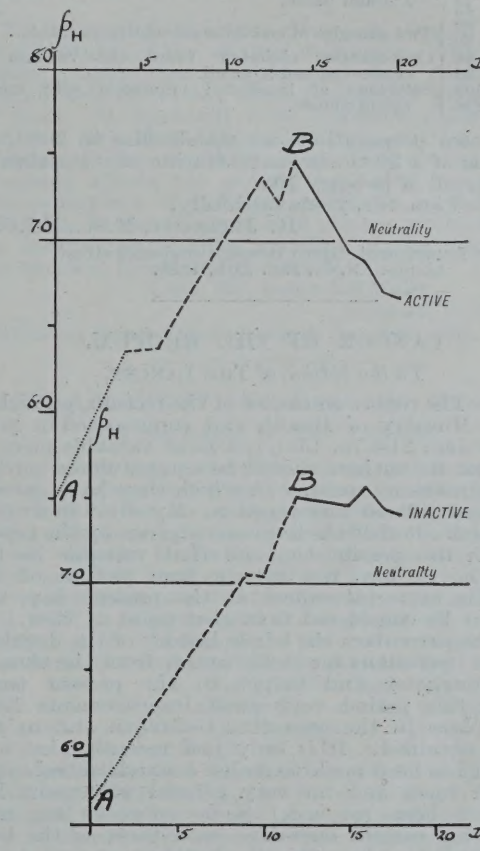
We were very forcibly compelled to recognise this difficulty when we began some four years ago to prepare from cod-liver oil a vitamin D concentrate. It was necessary, if this product was to give clinical satisfaction, to ensure its adequate content of vitamin D. This could only be achieved by assaying for vitamin D the oil used as raw material, by effectively controlling the manufacturing process, and by standardising the finished product. For such purposes a biological method of some accuracy and considerable rapidity was essential, in the absence of even the beginnings of a chemical test. After a survey of the various techniques then in use or proposed, it seemed clear that the only one likely to prove of service was that suggested by Zucker and Matzner.[1] This depends upon the change from alkalinity to acidity (pH over 7·0 to pH below 6·0) in the fæces of rats which have been placed upon certain diets high in calcium and low in phosphorus, and free from vitamin D. I personally had the advantage of instruction in the details of the test from Dr. Zucker himself in the laboratories of the College of Physicians and Surgeons, Columbia University, New York, and, after some slight modifications made in the light of experience, we adopted this method of assay. The procedure is fully described in a recent paper by myself and another.[2] After more than 2000 determinations of antirachitic potency carried out upon a wide variety of substances, and frequently checked both against chemical methods (bone analysis) and against histological methods (the so-called "line" test), we have been unable to avoid the conclusion that the rapidity and accuracy of this test gives it advantages over every other procedure. We may add that, since the publication of the paper referred to above, we have extended our observations upon the specificity of the test, and have found it quite negative in the cases of several inactive vegetable and animal oils, and positive in the cases of irradiated ergosterol, irradiated plant sterols, and other sources of vitamin D.

In order that determinations may be carried out in the shortest possible time a plentiful supply of young rats is essential. These are placed upon the experimental diet as a routine procedure, so that animals which have reached the desired fæcal alkalinity are always immediately available for use. In this way an estimation can be carried out with accuracy in five to seven days, using two, or at most four, animals. A considerable degree of skill in the technique is, however, essential, as is accurate (and incidentally expensive) apparatus for the electrometric determination of the fæcal pH. The progress of two typical assays from our routine test sheets is readily followed from the accompanying graph.



At A the animals have been placed on the experimental diet, and in the period A–B the pH of the fæces is steadily rising. At B the dose of the substance to be tested is given, and in the ensuing six days a rapid change in pH from an alkaline to an acid value is observed with the active, but not with the inactive, material. The test will only give the accuracy of a pharmacological assay if the dosage be adjusted so that the pH falls to below 6·90, but not below 6·60. If the fall is not to a point between these limits, the test must be repeated with the dosage adjusted to give the required fall; we have found the drop in pH to be reasonably closely proportionate to the vitamin D content over this range only. This point is being made the subject of a further communication from these laboratories to the Biochemical Society. The test, like the two colour tests for vitamin A, may be open to the objection of a want of specificity, but this does not seriously affect its usefulness. There is never any difficulty in discriminating between the "lactose effect" or "free acid effect" produced, as shown by Bergeim[3] and Zucker, Johnson, and Barnett[4] respectively, by relatively large quantities of appropriate substances and those produced by relatively small quantities of vitamin D-bearing material.

[1] T. F. Zucker and M. V. Matzner: Proc. Soc. Exp. Biol. Med., 1923, xxi., 186.
[2] H. Jephcott and A. L. Bacharach: Biochem. Jour., 1926, xx., 1351.
[3] O. Bergeim: Jour. Biol. Chem., 1926, lxx., 35.
[4] T. F. Zucker, W. C. Johnson, and M. Barnett: Proc. Soc. Exp. Biol. Med., 1922, xx., 20.

We entirely agree with the observations of Leigh Clare and Soames that there is great variation in the vitamin D content of cod-liver oils. We recently made a comparison of a number of oils with those which we have been using as our own raw material, as well as with a standard based on our examination of more than 200 samples of cod-liver oil during the last three years. Their relative vitamin D potency was as follows :—

A	100	Samples of our own oil before treatment.
B	113	
C	111	
D	108	
E	78	"Finest medicinal cod-liver oil"—one sold under a brand name.
F	53	
G	45	
H	90	Two samples of cod-liver oil sent from Cuba.
I	80	
J	86	Concentrates claiming twice the vitamin D content of cod-liver oil.
K	92	
L	500	Solutions of irradiated ergosterol sold under brand names.
M	230	

Our own preparations we standardise to 2000, on the basis of a 20 times concentration of "standard" cod-liver oil of potency 100.

I am, Sir, yours faithfully,

H. JEPHCOTT, M.Sc., F.I.C.

Ostelin Department, Glaxo House, Osnaburgh-street, London, N.W., Jan. 24th, 1928.

CANCER OF THE RECTUM.

To the Editor of THE LANCET.

SIR,—The report on cancer of the rectum, published by the Ministry of Health and summarised in your issue of Jan. 21st (p. 152), is a most valuable piece of work and its authors should be congratulated on the very painstaking manner in which they have carried out a most difficult investigation. My object in writing is to point out that the impression given by the report is much too pessimistic, and that valuable as the report is, it does not give a true picture of the prognosis in rectal cancer at the present day, nor should it be considered from that point of view.

The report covers the whole history of the development of operations for rectal cancer from the time of the Allinghams and Cripps to the present time. During this period very great improvements have taken place in the operative technique and in the results obtained. It is only just recently that any attempt has been made to realise a standard technique in such cases and no very general agreement has even yet been reached. Some surgeons are now recognising certain operative procedures as the best ones, but it is only within the last few years that any large numbers of cases treated by one standard technique have been performed. The figures in the Ministry's report include all the early cases, such as the operations of Allingham, Cripps, and Kraske, which have been completely out of date for a long time. It follows that both the mortality-rate and the survival-rate in the tables are quite unduly pessimistic as regards present-day conditions. Were it possible to compare the figures for the last decade with one of the earlier decades there would be a very marked difference, which, of course, cannot be brought out in the tables. For instance, the chief causes of death in the mortality tables are sepsis and shock, which account for no less than 370 out of a total of 452 deaths. Both these causes of death have been very greatly reduced by modern technique, and deaths from these causes should seldom occur at the present day. Again, the more extensive resections of the present day give a much better survival-rate than is indicated by the figures in the report. The chances of survival after a perineal operation for an average case of cancer of the rectum on a five years' basis (the tables only take a three years' basis) is over 50 per cent., while the chances for a case above the average, that is to say, an early case, is nearly 75 per cent.

Another most important factor cannot be allowed for in the tables. In the early days of operations for rectal cancer only the very favourable cases where t growth was within easy reach and comparative small were operated upon, the remainder being co sidered inoperable. With the improvement in t technique the limit of operability has been very mu extended, so that a far large proportion of cases a now operated upon than was formerly the case. Th while it improves the true figures—namely, the numb of cases cured out of 100 cases of cancer diagnos (a figure which up to the present no one has work out)—tends to give *a worse impression* of the figu based only upon cases operated upon. The tabl show clearly the advantages of the perineal operati over the combined route for the removal of rect growths where this is possible, and this conforms modern experience.

There is one conclusion from the tables whi I believe to be entirely erroneous. The tables appe to show that cancer of the rectum in young perso does not kill more rapidly than in older patien This is contrary to all surgical experience. In r experience most of the young patients (under 30 yea of age) who get cancer of the rectum are found to hopelessly inoperable when first seen ; this cannot shown in the tables. I have personally never seen case of cancer in a patient under 30 who survivl more than a few months, whether operated upon or n

I am, Sir, yours faithfully,

J. P. LOCKHART-MUMMERY.

Hyde Park-place, W., Jan. 28th, 1928.

COMMISSIONS IN THE R.A.M.C.

To the Editor of THE LANCET.

SIR,—Colonel J. Griffiths's letter of Jan. 2 showed the wisdom that any of his old fell students of years ago would expect. He thin the advantages of the R.A.M.C. are "almost beyo the conception and belief of the medical stude Would-be entrants are, however, few," and lest t splendid post-graduate college is scrapped, he wo pass some or all of the medical officers for overs through it. Certainly every free-trade nation h in the past, been forced to economise on its defens services. The benefits of the Service career regular, and now increased, pay, no bills to send fixity of tenure, constant help from friendly colleagu use of laboratories, and post-graduate instruct without cost. The drawbacks are changes of stat (to many their own compensation) and involunt retirement, by which the general practitione best years are lost. But there is the pension.

I submit that the attitude to the defensive servi is wrong. Recruiting is encouraged, the men well looked after in their services, but places are provided fo them afterwards. Vocational train is provided by the services. The Admiralty quali men for the City and Guilds of London Institut ecrtificate, which puts its electricians on an equal with others from outside when applying for po Why should not we see that the same thing is d for the best of the other ranks in the R.A.M.C. the sick berth staff ? I probed this when in Service, but the time was not auspicious. The Na has not the large scope of the Indian Service and R.A.M.C., but I cannot see why it is not joined w the Metropolitan Asylums Board, with which I ser for a short time in the war. It would take cour and time to make the change, passing officers fr one to the other every two or three years. Furth why should not officers be encouraged by th Directors-General to apply for billets in the hea or other services ; they will have done someth for their country in their spells of active serv And they would only capture civil posts if of spe record ; some would certainly succeed, for we h such conspicuously among us. And the more g men advertised the Services by winning good appo ments, the better would recruiting become.

I am, Sir, yours faithfully,

Piccadilly, W., Jan. 27th, 1928. W. E. HOME

AURAL SYSTEMIC INFECTION.

To the Editor of THE LANCET.

SIR—I am deeply indebted to a letter which appeared your issue of Jan. 7th from Mr. H. Ross Souper regard to the effects he obtained from the use of ntistreptococcus serum in cases of aural systemic fection.

A nurse at Cheltenham General Hospital became ill 3 A.M. on Jan. 1st with vomiting, sore-throat, eneral aching, and malaise. The following day there as follicular tonsillitis, and on Jan. 4th there was vere hæmaturia. On Jan. 6th there was acute ain in the right ear with slight œdema over the astoid, followed by profuse otorrhœa the following ay. On Jan. 10th cellulitis appeared on each side the nose, and spread over the whole face; small ebs formed over both cheeks and on the forehead. he patient had spasms of hiccough. On Jan. 12th iere was repeated vomiting. The temperature ictuated up to 104° F. On Jan. 13th streptococci ere recovered from blood taken from a vein in ie elbow on Jan. 11th. The patient now looked angerous ill, and I felt anxious about her recovery. n Jan. 14th 15 c.cm. of *Scarlet Fever* Antistrepto-occus serum (P., D. and Co.) were injected into ie glutei. The temperature fell to normal in 12 hours, id did not again rise above normal. The otorrhœa id the cellulitis of the face cleared up in a few days, ie hæmaturia ceased in 48 hours, and the albumin ll from 3½ parts to ½ per 1000. The improvement her whole condition was dramatic. I should ention that I had the collaboration of my colleague, r. N. H. Pike, in the treatment of the ear, and of r. J. B. Davey in the pathology of the case.

I am, Sir, yours faithfully,

Cheltenham, Jan. 30th, 1928. J. RUPERT COLLINS.

ITAMIN B AND THE ALIMENTARY CANAL.

To the Editor of THE LANCET.

SIR,—A number of communications have appeared ecently in which evidence was brought forward that itamin B exerts its action principally on the alimentary anal; thus Rowlands and Browning in your issue of an. 28th report dilatation of the stomach in vitamin B eficiency and refer to their previous finding of npaired motility of the intestines in this condition. is perhaps worth drawing attention to older work, hich has apparently been overlooked, in which very milar conclusions were come to, at a time when iochemical opinion inclined strongly to the view that itamin B (and the other accessory food factors) were ecessary for the normal metabolism of cells in general nd did not exert a selective action on the functions of pecial organs or tissues.

Thus Lumière [1] fed pigeons on decorticated rice and oticed a marked diminution of intake of food. There as evidence of stasis in the upper part of the digestive act. Trituration in the stomach was defective and ie onward passage of the bolus through the pylorus as greatly delayed. There was deficient glandular ecretion and hypotonus of the intestinal wall. A nall dose of extract of rice polishings provoked bundant glandular secretion and strong intestinal iovements which resulted in rapid evacuation of the lasses of polished rice lying in the upper intestine; err found in experiments on dogs [2] and I found in he case of rats [3] that in the absence of vitamin B the ntake of food was greatly diminished; when the itamin was restored to the diet food consumption as increased. Cowgill [4] utilised these results as a est for the presence of vitamin B in different food-tuffs. He found that the potency in promoting ppetite ran parallel to the potency in relieving symptoms in polyneuritic animals. Cramer and his co-workers showed in their important paper in THE LANCET [5] that in vitamin B deficiency there was lymphopenia, atrophy of the lymphoid tissues of the intestine and elsewhere, and defective absorption of fat. Both Cramer and I showed [6] that the stomach was dilated in this condition, and that there was probably "some defect in the power of the stomach to deal with its contents and propel them farther down the intestine." I suggested that the low food intake could be explained as follows: "The stomach is never empty; it is always partly distended with fermenting material. Hunger contractions do not take place, the craving for food becomes low, and the intake falls off."

The lowered food intake does not account for all the symptoms of the vitamin deficiency; Forster, for instance, found that dogs succumb more readily on a vitamin-free diet than when completely deprived of all food. It appeared from Cramer's observations and my own that the unhealthy condition of the intestine might result in toxic absorption which adversely affects the general health of the animal. The symptoms of beri-beri might be explained as being due to the absorption of poisons which damage the nervous or vascular systems, giving rise to the dry and wet forms of the disease.

I am, Sir, yours faithfully,

SAMSON WRIGHT.

THE APPARENT INCREASE OF CANCER.

To the Editor of THE LANCET.

SIR,—Will you permit me to say a few words on the annotation under this heading in your issue of Jan. 28th? It is to be regretted that my illustration of the difference between crude and standardised rates should appear to have done an injustice to Dr. Stevenson, and I will substitute, if I may, a comparison between similar rates for the buccal cavity in 1901–05 and 1925, as in your opinion it is preferable to take a group of years. In this period the crude rate per million rose from 113 to 142 while the standardised rate fell from 154 to 142, the standardised figures being 2834 and 2649, a fall which does not appear to be recorded in either of Dr. Stevenson's reports.

Your defence of the, to me, artificial division of sites into accessible and inaccessible rests on diagnostic facilities. There has been no increase of such facilities in regard to the buccal cavity, which must be regarded as a whole not only from the close anatomical relationship of its sites, but because, as a reference to the table given on p. 550 of the annual report for 1913 shows, even so recently as 1912, at no site in the group can the records be accepted as an accurate statement containing all deaths due to a primary cancer at that site and no others. There has been sufficient overlapping of sites to make it necessary to treat the group as a whole. Since 1901–05 there has been no increase of diagnostic facilities and no increase of cancer in the buccal cavity. At the other extreme there has been a marked increase of diagnostic facilities—e.g., X rays and bismuth meals, bronchoscopy, and genito-urinary surgery, and a coincident large increase of cancer at the sites corresponding. Diagnostic facilities may be a perfectly sound basis for instituting a comparison, but they do not form the distinguishing character between the groups termed accessible and inaccessible. The distinction made by the U.S.A. inquiry was between certain and uncertain diagnoses, a distinction which seems to me quite valueless for purposes of comparison.

I may add that a solution of the problem of the increase of cancer is not so much of importance in order to allay the alarms of the public as because it has a direct bearing on causation and hence on the direction in which research should move. It should be

[5] THE LANCET, 1921, ii., 1202.
[6] Loc. cit.

taken, if possible, out of the region of personal opinion; and we can start with the fact that cancer of the male buccal cavity has not increased from the beginning of the century up to 1925.

I am, Sir, yours faithfully,

London, Jan. 28th, 1928. D. F. SHEARER.

GASTRO-DUODENAL ULCERATION.

To the Editor of THE LANCET.

SIR,—I should like, as a general practitioner, to thank Prof. MacLean and his collaborators for their excellent and helpful article on the intensive alkaline treatment of gastric and duodenal ulceration. In the course of work as a hospital resident I have seen excellent results follow various other forms of medical treatment, but each of these required (*a*) special diet governed by long tables, (*b*) skilled nursing. These necessities make such treatment difficult for those whose work lies in small towns or villages scattered throughout Great Britain, and it was surely for such rather than for the pundits of Harley-street and Wimpole-street. It offers a method which can be quite easily carried out in the patient's own home, be that latter a two-roomed cottage.

Hundreds of general practitioners will be exceedingly glad if they can get immediate results as good as those put forward in the articles from St. Thomas's. Why should we be refused the information which will make this possible whilst cases are watched, like organisms under a microscope, for another 5, 10, 15, or 20 years? I, for one, feel deeply grateful to Prof. MacLean and his colleagues for having preferred to expose themselves to the accusation, by implication, of being unfair, unscientific, and extravagant. Very few can have read into the article in question any claim to infallibility.

One would like to hear from Dr. Ryle what proportion of men engaged in general practice can find the time, even if they have the inclination, to verify references given in the average bibliography.

I am, Sir, yours faithfully,

DONALD M. O'CONNOR.

Malmesbury, Wilts, Jan. 27th, 1928.

To the Editor of THE LANCET.

SIR,—May I, as one who was employed in general practice for 28 years and who has not long come from it, express the gratitude I felt on reading the paper by Prof. Hugh MacLean and his colleagues in the issue of Jan. 7th, the substance of which was so important and whose value to me was enhanced by the manner in which it was presented. My only regret was that such a fundamental matter was not settled years ago, for in retrospect one can see what relief might have been given to numbers of cases had one not been afraid of alkalosis, a bogy which is now laid low for ever.

To me it would be no surprise to hear that hundreds of people have been relieved already with an expeditiousness directly due to the fact that the paper was unencumbered with references. Time for reading is hard to find in any busy practice and my impression is that many do as I did; that is, read the papers with few or no references first and reserve those with a long list attached to them until one has the leisure to read them.

My recollection of Prof. MacLean's papers in the past is that they were rather of the latter kind, intensely interesting, but requiring much time to enjoy them thoroughly. Can we hope he may be persuaded to give us more in his recent vein? Were he to prove that other things which stay our hands at present are only bogies such relief, such gratitude would come, that few indeed will be found so churlish as to say this or that part of the work was only confirmatory—our sense of obligation would be too great.

I am, Sir, yours faithfully,

Guildford, Jan. 31st, 1928. HERBERT W. NOTT.

THE FUTURE OF MEDICAL PRACTICE.

To the Editor of THE LANCET.

SIR,—Dr. Cyril Doyle in your issue of Jan. 28 on the Future of Medical Practice asserts th "other clinics—e.g., tonsils and adenoids, dent maternity, and child welfare—are becoming increasingly unpopular with the patients and the practioners, so also are the poor-law hospitals." W regard to the latter point I agree with the stateme of Dr. J. C. Muir in THE LANCET of the same da that the poor-law hospitals are becoming increasing popular. Might not Dr. Doyle wait a few m years before he can judge so important a matte

I have had 12 years' experience of general pract and 18 years as medical officer of health and sch medical officer. When I first commenced my dut as school medical officer we had about half a doz patients in attendance at the clinics; now we aver between 80 and 90, disproving the unpopularity f the clinics. The general practitioners in this borou frequently refer cases to the clinic for treatment.

Dr. Doyle states that "the reasons for t unpopularity of the clinics are not difficult to tra because the general practitioner who has charge f the patient after clinic treatment hears the patien ideas and is able personally to observe the result f such treatment." But the operations for tons and adenoids are usually performed at hospitals a the cases are notified to the school medical offi to follow up—not to the general practitioner.

He further states "that compulsory medi examination at school sometimes leads to expressio of opinion by the school doctor which differ fr opinions previously given by the family practition These occasional conflicts of opinion do much towa weakening faith in school doctors." This is usua the reverse. He also says that "many a moth brings her child to me to enucleate its tonsils or 'give it an overhaul' rather than go to the provic centre." I have always understood that consulta would only see cases referred to them by gene practitioners.

Statistics show that the greatest reduction in mortality-rate is chiefly in the poor localities, beca it is the poorer people who are encouraged to atte the welfare centres. Our infant mortality-rate 1904 was 154 and 56 in 1926. I should like Doyle to visit any of our clinics to see and hear himself as to the alleged "unpopularity of clinic He would find that it is not for "the desire to something for nothing," as he states, but to obt treatment that would otherwise not be obtain I would further suggest that he obtains and re Sir George Newman's report on "The Health of School Child."—I am, Sir, yours faithfully,

W. BENTON,
M.O.H. and School M.O., County Boro
Jan. 30th, 1928. of East Ham.

NOMENCLATURE.

To the Editor of THE LANCET.

SIR,—Your leading article of Jan. 28th sta the position with an admirable clearness and brea of vision, but such clearness is by no means gene and it sometimes happens that scientific controver are entirely based on the different meaning attribu to the same word by various writers. The Minis of Health has recently and most usefully defi what is meant by "quiescent, arrested, and cure when applied to pulmonary tuberculosis, and it wo be similarly advantageous if an equally authoritat body would bring up to date the accepted meaning many words currently used in scientific medici The duties of such a definition committee would largely dictionary work, plus recommendations. finality would be attained or even aimed at. Almroth Wright has often pointed out that clearn of thought depends on a clear terminology.

I am, Sir, yours faithfully,

Paignton, Jan. 28th, 1928. E. WARD

Obituary.

ROBERT ARTHUR MILLIGAN, O.B.E., M.D. DURH., J.P.

By the death of Dr. R. A. Milligan on Jan. 25th orthampton loses one of its outstanding citizens d a medical man who was justly held in great teem in the town and county. Born at Dean, near mbolton, he came of a Scottish family, and was ucated at Clevedon College, Northampton. When ly 17 years of age he attached himself to the actice of Northampton Hospital, proceeding later Guy's where he showed himself an all-round hlete. He qualified as M.R.C.S. in 1881, and after ting as house surgeon and resident obstetrician at uy's, and anæsthetist at the Evelina Hospital, he urned to Northampton and was appointed surgeon the General Hospital there. In the 40 years ring which he held this post he acquired an mense experience, and established a reputation ich led practitioners over a wide area to ask his lp in difficult surgical and obstetrical cases. In dition to surgical practice, Dr. Milligan was senior dical officer to the venereal clinic for Northampton, d he was one of the pioneers in the ambulance vement in the neighbourhood. At the outbreak the war he gave up his private work to take a ajor's commission in the Royal Army Medical rps and gave able service in the First Eastern neral Hospital at Cambridge. In recognition of is work he was made an Officer of the Order of the itish Empire. Dr. Milligan became a magistrate 1908 and served as alderman on the town council 23 years, presiding over the public health comttee; his professional duties made it impossible him to accept the office of mayor, which was veral times offered to him. He was also keenly erested in Rugby football, and seldom missed ending a match on the local ground, where his ofessional services were often called upon.

A colleague and former house surgeon, to whom we e indebted for some of these biographical details, vites of him as follows: "Dr. Milligan was a man imposing physique, whose bluff and cheery manner de him popular with all classes. Of wide perience and sound judgment, he made up his nd quickly and was seldom wrong in diagnosis prognosis. As an operator, if not brilliant, he s essentially sound, and he obtained results surssed by few. Although not carried away by passing shs, he was quick to adopt new methods. A man of w words in professional matters, he inspired great nfidence in his patients. He loved his hospital rk, and although his large figure and loud voice ded to alarm a new probationer, the nursing staff re devoted to him. The amount of work that he d for nothing will never be known, but it was a mmon complaint, even among the comparatively ll-to-do patients, that they could not get a bill t of him. None knew better than he the end he ght expect and he faced it courageously."

Dr. Milligan leaves a widow and four daughters; fifth daughter died three years ago.

CLAUDE WILLIAM SCOTT SABERTON, M.D. MANCH., D.M.R.E.

WE have to record the death at Bournemouth on Jan. 16th of Dr. C. W. S. Saberton. Elder son of the late Dr. F. W. Saberton, of Manchester, he was educated at Owens College, and graduated as M.B. in the Victoria University in 1901. After a period as demonstrator of anatomy at Owens College, he practised for a short time as his father's partner, but early in his career he became interested in radiology and moved to Bournemouth where he was appointed hon. radiologist to the Royal Victoria and West Hants Hospital. Never robust, the strain of war-time work was responsible for his early exemption from military service, and in 1916 he went to Harrogate where he was appointed hon. radiologist to the Infirmary and to the Royal Bath Hospital. It was characteristic of him to undertake this work at a time when his physical condition would have justified him in avoiding any additional strain, and he put his fullest energy and enthusiasm into his hospital as well as his private practice. He took the D.M.R.E. at Cambridge in 1921, and during his seven years in Harrogate established a reputation as a leading radiologist. A pioneer in the application of diathermy he was also one of the first to introduce the deep X ray treatment into England, having made a journey to Erlangen to study the technique. His interests were various, and he was well known at St. Moritz as a skilful curler. Ill-health, however, forced his retirement a few years ago and he went back to live at Bournemouth. "Saberton," writes a colleague, "will be remembered by all who had the privilege of knowing him as one of the kindest and most generous of men. He made a very gallant fight against the ailment which caused his early retirement from practice in 1923, and which ultimately caused his untimely death."

He leaves a widow and one daughter.

JAMES CLEMENT BAXTER, L.R.C.P. IREL., J.P.

THE death occurred on Jan. 27th at his home in Everton, Liverpool, of Dr. J. C. Baxter, at the age of 71. A native of Liverpool, he was educated at St. Xavier's College, studied at the Liverpool School of Medicine, and qualified as L.R.C.P. in 1878. His practice in the district was considerable, and outside medical circles he was well known for his interest in Association football, serving for 38 years as a director of the Everton Football Club. He also acted as medical adviser to the club until a few years ago when he was succeeded in this office by his son, Dr. C. S. Baxter. He was appointed a magistrate for the city of Liverpool in 1906, and from that year until 1920 was a member of the city council. Dr. Baxter leaves a widow and two sons, both of whom are members of the medical profession.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lts. W. R. S. Panckridge to *Alecto* and S. G. Weldon to *Veronica*.

Surg. Lt. G. S. Rutherford to rank of Surg. Lt.-Comdr.

M.D.—A. A. Gemmell and E. H. V. Hodge.
M.B. and B.Chir.—E. S. Bolton, W. F. Cooper, and C. P. Pinckney.
M.B.—W. G. S. Hopkirk.
B.Chir.—J. W. D. Buttery and D. F. Lawson.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary quarterly Comitia of the College was held on Jan. 26th, with Sir John Rose Bradford, the President, in the chair. The following candidates, having satisfied the Censor's Board, were elected Members of the College:—

Roland George Anderson, Godfrey William Bamber, Donald Campbell, Clement Clapton Chesterman, Ronald Cove-Smith, William Hofmeyr Craib, Sheldon Francis Dudley, William Norwood East, Abd el Kader Hilmi El-Shurbagi, William Evans, John Rex Godsall, Cecil William Hutt, Una Christina Ledingham, Noel Vernon McKenna, Basil William Sholto Mackenzie, Richard Glyn Maliphant, Phillip Justin Markell, Albert Victor Neale, Alexander Adam McIntosh Nicol, Charles Bruce Perry, Ronald Arthur Phillips, John Douglas Procter, Reginald Hans Taylor Rea, Abd el-Azim Yousif Mostafa Salama, Sydney Watson Smith, Howard Hilton Stewart, Charles Cady Ungley, Marion Boyd Wanliss, and Lawrence Stuart Woolf.

Licences to practise were conferred upon 120 candidates (92 men and 28 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

R. Anderson, Cambridge and Birmingham; G. D. Augenlicht, Rostov and Westminster; L. Bernard, London; F. G. Booker, Cambridge and Guy's; G. N. Box, St. Thomas's; M. S. R. Broadbent, Cambridge and St. Bart.'s; J. W. Bromley, Cambridge and London; C. E. S. Bullen, Leeds; Eleanor M. Carless, Royal Free; A. M. Chaudhuri, Calcutta and St. Bart.'s; S. S. Chesser, Cambridge and St. Thomas's; T. L. Cleave, Bristol; G. A. Coggin, London; C. N. Cohen, Guy's; C. C. Cookson, Birmingham; N. Cox, Manchester; Pera R. C. Crawford, Royal Free; W. S. Creer, Liverpool; D. S. Davies, Oxford and Guy's; E. R. L. Davies, Cardiff; Helena M. de Hartog, Royal Free and St. Mary's; M. M. Dey, Leeds; Olivia F. Digby-Smith, Cardiff; H. Doyle, Calcutta and St. Mary's; M. R. Doyle and C. B. Drew, St. Thomas's; J. St. C. Elkington, Cambridge and St. Thomas's; Alexandra G. H. English, Royal Free; A. G. Ensor and H. Epstein, Guy's; M. M. Fikri, Cairo; John Foster, Cambridge and London; H. D. F. Fraser, St. Bart.'s; Mabel O. Cassels Freeston, Royal Free; T. R. Gaha, Sydney and St. Mary's; P. J. Ganner, Birmingham; Caterina P. Giles, Cambridge and King's Coll.; E. M. Goitein, University Coll.; R. A. P. Gray, Cambridge and St. Bart.'s; C. R. Green, Oxford and Westminster; C. S. Gross, Guy's; Bridget S. P. Gurney, Royal Free; B. Haring, Manchester; R. M. J. Harper, Oxford and St. Thomas's; J. Harris, Adelaide and London; R. L. Harward, Guy's; N. F. Haslam, Birmingham; J. C. Hatrick, University Coll.; L. Hennell, Manitoba and Middlesex; Margaret A. L. Herbertson, Oxford and King's Coll.; Anna M. Hilliard, Toronto; E. A. H. Hindhaugh London; N. M. Hodivala, Bombay and London; Josephine M. Howells, Westminster; W. H. Hubert, Cambridge and St. George's; W. L. Hurn, St. Bart.'s; A. L. Hyatt, Middlesex; Dorothy M. James, Cardiff; D. C. R. R. Jenkins, St. Bart.'s; I. J. Jones, St. Thomas's; R. T. Jones, Cardiff and Guy's; H. Kaitz, Guy's; Alison R. Kerridge, Royal Free; A. K. M. Khan, Bombay and Middlesex; P. Kuhne, Lausanne and Charing Cross; T. E. Lamech, Cambridge and St. Thomas's; B. A. Lamprell, King's Coll.; W. J. Lloyd, Cambridge and St. Bart.'s; Margaret I. Meacock, Cardiff and Westminster; A. A. Miles, Cambridge and St. Bart.'s; Mary M. Moore, Royal Free; C. F. Moore, St. Bart.'s; C. S. Morton, St. Thomas's; W. H. Myburgh, Cape and Guy's; J. O'Donoghue, London; Lois J. Ogle, Royal Free; E. N. O'Neill, St. Mary's; Ella M. Oswald, Royal Free; T. N. Parish, King's Coll.; W. E. C. Parry, Cambridge and University Coll.; P. I. Peltz, St. Bart.'s; P. P. Pess, Ceylon and King's Coll.; C. D. Politeyan, Cambridge and St. Thomas's; A. E. Porritt and Monica M. M. Power, St. Mary's; J. C. Preston, Manchester; Agnes M. Ramsbotham, Royal Free; W. G. Richards, St. Thomas's; J. H. Richmond, Cambridge and Guy's; T. McK. Robb, Guy's; F. E. Roberts, Birmingham; Elizabeth J. Robin, King's Coll.; Florence E. Robinson, Royal Free; F. S. Rudland, Birmingham; Margaret M. Russell, King's Coll.; R. W. Sabonadiere, St. Thomas's; W. J. M. Sa[illegible], University Coll.; H. A. Seidenberg, St. Bart.'s; Dori[illegible] Sharvelle, King's Coll.; D. C. Shields, St. Georg[illegible] Clarice A. Skidmore, St. Mary's; T. E. Skinner and W. D. Steel, Birmingham; G. Steinberg, Bristol; W. P. R. Swemmer, Guy's; B. A. Taylor, Manchester; Dor[illegible] Tims, Charing Cross; Ruth M. W. Turner, Cambridge and St. Mary's; D. R. Tweedie, Cambridge and St. Bar[illegible] G. P. A. van Rossum, Cape and St. Bart.'s; J. A. Ver[illegible] Guy's; Elizabeth H. Waller, Charing Cross; H. S. Wa[illegible] Cambridge and St. Mary's; K. H. Watkins, Manches[illegible] I. Waynik, Cape and Charing Cross; C. H. C. W[illegible] Guy's; H. O. White, St. Bart.'s; Hannah E. W[illegible] Royal Free; E. A. Wood, University Coll.; and N. R. Wynn Williams, Middlesex.

A supplemental list of licentiates will be issued later of the candidates whose examination is still in progress.

The undermentioned diplomas were also conferred conjointly with the Royal College of Surgeons, to following candidates:—

Diploma in Psychological Medicine.—W. A. Caldwell, I. Cook, I. Frost, N. G. Harris, E. J. C. Hewitt, R. G. Marsh, N. R. Phillips, R. P. Rees, and H. H. Steadman.
Diploma in Laryngology and Otology.—H. Bahgat, R. E. Buckingham, H. S. Chhachhi, H. A. Cowan, S. Da[illegible] E. M. Dearn, H. G. Downer, R. A. Highmoor, Barbar[illegible] Logan, P. MacMurray, J. H. O'Donnell, A. M. Ross, [illegible] Sen, J. J. Stander, P. Subbaramayya, and H. L. Vaid.
Diploma in Public Health.—F. Asker, A. D. Belilios, [illegible] Benjamin, W. A. Brown, Isabella M. G. Butler, Dor[illegible] M. Catchpool, N. E. Chadwick, Nancy M. Coutts, A. V. Crawford, R. N. Curnow, Gweneth M. Daniel, Hild[illegible] Dean, E. L. F. De Mel, Kathleen Dickinson, Christ[illegible] S. Eyre, Nancy K. Gibbs, Gladys Goument, W. H. Hamilton, R. S. Johnson, M. H. Khan, F. E. R. Labo[illegible] Eroica R. Lewis, K. L. Malhautra, H. L. Malhotra, [illegible] W. Morris, G. Napier, H. A. A. Pargeter, B. L. Pat[illegible] K. P. Pillai, T. A. Seekings, S. R. A. Shah, Kath[illegible] Shelton, C. H. C. Toussaint, S. N. Wasti, P. L. W[illegible] and C. A. Wood.
Diploma in Ophthalmic Medicine and Surgery.—H. K. [illegible] J. C. Bringan, A. E. F. Chaffer, E. J. Collins, S. D[illegible] G. I. Evans, B. F. Eminson, E. R. Jagger, M. S. K[illegible] B. Kay, R. B. Khare, L. R. Lalwani, G. D. Malho[illegible] M. A. Mithavala, D. Patwardhan, W. J. Riddell, Loui[illegible] Rubidge, D. D. S. Stewart, and C. R. Verling-Brown.

Dr. A. E. Russell was elected to the Council in the [illegible] of the late Sir Percy Bassett-Smith.—Communications [illegible] received: (1) from the Secretary of the Royal Colleg[illegible] Surgeons; (2) from the Medical Secretary of the Br[illegible] Medical Association; (3) from the President and Counc[illegible] the Institute of Chemistry of Great Britain and Ireland.—[illegible] Monckton Copeman was appointed to represent the Co[illegible] at the Thirty-ninth Congress of the Royal Sanitary Instit[illegible] —Sir Leonard Rogers was appointed as delegate to [illegible] centenary celebration of the Faculty of Medicine, Cair[illegible] response to the invitation of the Minister of Education of [illegible] Kingdom of Egypt.—Communications were received f[illegible] the President of the University of Toronto and from [illegible] R. D. Rudolph with reference to the recent celebration of [illegible] centenary of King's College, Toronto.—A report [illegible] received from the representative of the College on [illegible] General Medical Council.—Dr. C. O. Hawthorne reported [illegible] the Departmental Committee of the Optical Practitio[illegible] Registration Bill.—Books and other donations to the lib[illegible] presented during the last quarter were received and tha[illegible] were returned to the donors.—The annual report of [illegible] examiners for the Licence on the examination held in [illegible] year 1927 was received.

MEDICAL FACULTY OF INNSBRUCK.—Prof. Georg[illegible] Gruber, Dean of the Faculty, announces the holding [illegible] post-graduate course for practitioners at Innsbruck f[illegible] March 12th to 18th. Each morning is occupied f[illegible] 8 to 1 with a series of five systematic lectures or demons[illegible] tions in medicine, surgery, or special subjects, and a[illegible] from 3 to 5 in the afternoons except Wednesday. Instruc[illegible] is given in each case by the professor in the Faculty. T[illegible] is an entrance fee of 20 schillings (about 14*s.*), and all [illegible] wish to take part should register before March 10th [illegible] the Dean of the Medical Faculty, Innsbruck.

SOCIETY OF APOTHECARIES OF LONDON.—At recent minations the following candidates were successful:—
urgery.—G. N. Fox, St. Bart.'s Hosp.; A. W. Lassowsky, Basle and Middlesex Hosp.; and J. R. Mitchell, Liverpool.
Iedicine.—G. N. Fox, St. Bart.'s Hosp., and D. I. Jones, Univ. Coll. and St. George's Hosp.
'orensic Medicine.—G. N. Beeston, Charing Cross Hosp.; B. P. Jones, Manchester; D. I. Jones, Univ. Coll. and St. George's Hosps.; A. W. Lassowsky, Basle and Middlesex Hosp.; and J. R. Mitchell, Liverpool.
Iidwifery.—W. B. Hallums and H. T. Ince, St. Mary's Hosp.; E. A. Johnstone, Manchester; and H. D. K. Wright, St. Bart.'s Hosp.
he Diploma of the Society entitling candidates to practise licine, surgery, and midwifery was granted to D. I. Jones A. W. Lassowsky.

UNIVERSITY OF LONDON.—At a meeting of the ate held on Jan. 25th Mr. M. E. Delafield, M.B. Camb., P.H., was appointed as from a date to be determined sequently to the University Chair of Chemistry as applied Hygiene, tenable at the London School of Hygiene and pical Medicine. Dr. Delafield was educated at Merchant lors' School, Jesus College, Cambridge, and St. Thomas's spital. He took a first class in the Natural Science Tripos 1907, and graduated as M.B. in 1910. From that year il 1916 he was engaged in medical practice, and from 5–16 was a temporary medical school inspector for the don County Council. He saw military service from 1916 919, being awarded the Military Cross, and for the next years was deputy medical officer of health for Stoke vington and head of the Sanitary Science Department of L.C.C. Hackney Institute. From 1920–24 he was also stant in the Department of Public Health and Hygiene University College, and since 1925 he has been head of department.
r. E. L. Kennaway was awarded the William Julius kle Fellowship for 1928 in respect of the work he has ied out on cancer research during the past five years. Fellowship this year is of the value of about £275.
Ir. H. L. Eason was appointed to represent the University the General Medical Council.
r. W. J. O'Donovan, physician to the skin department he London Hospital, has been admitted to membership he Faculty of Medicine.
uy's Hospital Medical School.—Lectures on the Surgery he Kidney and Ureter will be given at this school by Mr. ham Simpson on Fridays, Feb. 10th, 17th, and 24th, 5.30 P.M. Admission free without ticket.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE DICAL ASSOCIATION.—On Monday, Feb. 6th, at 5 P.M., the Medical Society of London, 11, Chandos-street, endish-square, W. 1, Dr. R. M. Stewart will lecture Secondary Forms of Mental Deficiency. On the same , at 2.30 P.M., at St. Mark's Hospital, Mr. J. P. Lockhart-mmery will give a clinical demonstration. On Friday, . 10th, from 2 to 3 P.M., at the Paddington Green ldren's Hospital, Dr. G. A. Sutherland will give a clinical monstration, and on the same day, at 5 P.M., at the Royal stminster Ophthalmic Hospital, Mr. C. L. Gimblett will a clinical demonstration on Cataract. The lecture and demonstrations are open to members of the medical fession without fee. From Feb. 6th to Feb. 18th a cial course in Diseases of Children will be given at the ldington Green Children's Hospital and at the Victoria spital for Children; sessions will be held alternately at h hospital, and will include lectures, demonstrations, operations. From Feb. 20th, for four weeks, a course in ereal Diseases will be given at the London Lock Hospital ing the afternoons and some evenings, consisting of ical instruction and lectures. The course has been poned from Feb. 6th. As the lectures will only be given here is an entry of six, early application should be made. m Feb. 20th to March 3rd, at the Queen Mary's Hospital, tford, an all-day course will be held in medicine, surgery, the specialties, at which lectures and demonstrations be given and operations performed. Information, abuses of special and general courses, tickets, and copies he *Post-Graduate Medical Journal* may be had from the retary of the Fellowship at 1, Wimpole-street, London, W.

THE fifth International Medical Congress for ustrial Accidents and Occupational Diseases is to be held in lapest from Sept. 2nd to 8th. Addresses will be given, ongst others, by Prof. J. Liniger, Dr. F. Zollinger, Prof. B. Lehmann, Sir Thomas Oliver, Prof. J. G. Sleeswijk, Prof. ten, Prof. Koelsch, Prof. Julius van der Hoeve, and Prof. phan Jellinek. Although industrial diseases will receive sideration, particular prominence will be given in the gramme to industrial accidents, as in 1929 a congress cially devoted to diseases is to be held in Lyons under auspices of the Congress for Occupational Diseases. Council of Industrial Medicine has been nominated to as the British National Committee, and further informa- can be had from the Secretary, 12, Stratford-place, don, W. 1.

NAVAL MEDICAL COMPASSIONATE FUND.—At the quarterly meeting of the directors, held on Jan. 24th, the sum of £115 was distributed among the several applicants.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting will be held at the Miller General Hospital, Greenwich, on Friday, Feb. 10th, at 8.45 P.M., when Dr. M. Travers Smith will give an address on the Origin and Diagnosis of Cardiac Murmurs.

HOSPITAL DEVELOPMENTS AT LEAMINGTON.—An orthopædic clinic for children under 14 is to be established at the Warneford Hospital, Leamington. The hospital is also about to undertake the training of pupil midwives, which has hitherto been conducted by the Warwickshire Nursing Association with the aid of a grant from the county.

PROPOSED IRISH PHARMACY BILL.—It is understood that the Government of the Irish Free State has been in consultation with representatives of the Pharmaceutical Society of Ireland for the purpose of framing a Bill to govern the practice of pharmacy. The heads of a Bill have been agreed on, and it is probable that legislation will shortly be undertaken.

HOSPITAL NEEDS IN SALFORD.—The Salford Guardians contemplate the provision of considerable additional hospital accommodation at the Union Infirmary. It is proposed to allocate 100 beds to the Corporation and 50 to the Royal Hospital, while the Union Infirmary itself needs 250 additional beds, making a total of 400. Since, however, it is thought desirable to provide a margin of accommodation, it is intended to provide 500 beds in all.

DENTAL PRACTICE IN VICTORIA (AUSTRALIA).—The Acting Agent-General for Victoria informs us of the receipt of a cablegram from his Government intimating that under an Act recently passed in the State the registration of British dentists is restricted solely to licentiates of British medical authorities and that the restrictions apply to all dentists who had not embarked for Victoria prior to Dec. 8th last. Most of the Dominions have, we understand, already made a similar restriction.

A COTTAGE HOSPITAL'S TREASURE.—A few years ago there was left to the Cottage Hospital at Moreton-in-the-Marsh in Gloucestershire a chair reputed to be that in which Charles I. sat during his trial in Westminster Hall. It is stated that the authorities of the Victoria and Albert Museum see no reason to doubt its authenticity, and negotiations for its purchase are far advanced. The chair will be placed in the furniture section of the museum.

BIRMINGHAM DENTAL HOSPITAL.—The annual report of this institution states that nearly 37,000 operations were performed during the past year, an increase of 1000. An extended use was made of local anæsthesia, and the demonstration room is to be equipped with up-to-date electrical appliances, including a compressed air installation which will serve both the conservancy and prosthetic departments. The number of radiographic examinations doubled during the year.

DENBIGHSHIRE HOSPITALS.—A shilling fund in aid of the endowment of the Breconshire War Memorial Hospital has been set on foot. It is intended as a memorial of the late Lord Glanusk, who died in the act of opening the hospital. The committee of visitors of the North Wales Mental Hospital at Denbigh propose to spend £80,000 upon the extension of the buildings. The hospital contains 98 patients over and above the proper accommodation, and lunacy is said to be increasing in the five North Wales counties at the rate of 20 cases per annum.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—On Jan. 30th the officers and staff of this hospital held a festival dinner at the Mansion House, to celebrate the completion of seven years' work, and to attempt to raise the sum of £40,000, to pay for the 200 beds for which provision has already been made at the country branch at Stanmore. In proposing the toast of "The Hospital," Prince Henry, the President, described the miraculous results which took place not only in the physique of the patients but in their mentality, and urged the economy of curing the nation's cripples rather than supporting them. Dr. Graham Little, M.P., who seconded, extolled the virtues of the voluntary hospital system, described the new country branch, and vigorously championed orthopædic surgery against the pretentious modern craft of osteopathy. Mr. H. E. West, the chairman, made a witty reply, at the end of which he drew the guests' attention to the cheques and fountain-pens which had been placed by their sides. The health of "The Guests" was proposed by Mr. Reginald McKenna, and answered by Sir Philip Gibbs. The guests included the Lord Mayor and Corporation, and the mayors of many of the London boroughs. The President announced that the subscriptions and presents received that evening had reached a total of £10,100.

EXTENSION OF LEEDS MATERNITY HOSPITAL.—Princess Mary last week laid the "panel stone" of the first part of an extension which will add two wings to this institution. The cost will be £60,000, of which a little more than half has been raised.

IMMUNISATION AGAINST DIPHTHERIA.—The Manchester Education Committee at its meeting on Jan. 23rd, after considering a report by its subcommittee and a report by the medical officer of health for the city on diphtheria immunisation, adopted a resolution "to approve of the principle of voluntary preventive inoculation against diphtheria. To coöperate with the Public Health Committee in the practical application of a suitable scheme." Nothing will be done until a scheme has been brought before the committee.

DONATIONS AND BEQUESTS.—Mr. Edward Martin, of Bishopsgate, London, left £1000 each to the London Hospital, Dr. Barnado's Homes, and the Salvation Army, and £250 to the Victoria Hospital, Southend-on-Sea.—Sir Edward Burnet James, of Bristol, left £1000 to the Bristol General Hospital, £500 each to the Bristol Royal Infirmary and the Bristol Benevolent Institution.—Mr. Joseph Frederick Read, of Watermillock, Penrith, formerly of Liverpool, solicitor, left, on the death of his wife, £1000 to the Liverpool Open-air Hospital for Children, £500 each to the Samaritan Hospital for Women, Wallasey Cottage Hospital, Liverpool Bluecoat Hospital, the Royal Seamen's Orphan Institution, and £200 to the Eye and Ear Infirmary, Liverpool, and on like conditions one-half of the residue for charitable or philanthropic institutions within a radius of 10 miles from the town hall of Liverpool, as the executors may think fit.—Mr. Henry Westmacott, Manchester, chemist, who left estate of the gross value of £6368, after certain small bequests left the residue of his property, about £5000, to the Manchester Royal Infirmary.—Mr. Algernon Preston, of Penmaenmawr, late of Sale, left £2000 to the Dental Hospital, Manchester, in memory of his son, Dr. Charles Henry Preston.—Miss Matilda Margaret Reid, of Hampstead, left more than £35,000 to charities, including £10,000 to the National Institution for the Blind and Earl Haig's British Legion Fund, and £5000 to Dr. Barnardo's Homes and two other institutions.

Medical Diary.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurolog Department. 2 P.M., Mr. MacDonald: Gen urinary Department. 2 P.M., Mr. Bishop Harm Eye Department.

FRIDAY.—10 A.M., Dr. Pritchard: Special Medical Tr ment Clinic. 2 P.M., Mr. Vlasto: Throat, Nose Ear Department. 2 P.M., Dr. Shaw: Medical C patients.

SATURDAY.—10 A.M., Dr. Burnford: Bacterial Thera 10 A.M., Dr. Owen: Medical Diseases of Children. Medical and Surgical Out-patients, Operations, Spe Departments, daily, 10 A.M. to 5 P.M., Saturd 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLE Prince of Wales's General Hospital, Tottenham.

MONDAY, Feb. 6th.—2.30 to 5 P.M., Medical, Surgical, Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Thr Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P Medical, Surgical, and Ear, Nose and Throat Clir Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clir 2.30 to 5 P.M., Surgical, Medical, and Childr Diseases Clinics. Operations.

On TUESDAY, Feb. 7th, and THURSDAY, Feb. 9th, at 2 P there will also be Special Demonstrations of Ear, N and Throat Cases and Medical Cases by Mr. Ibbotson and Dr. A. J. Whiting respectively.

NATIONAL HOSPITAL, Queen-square, Bloomsbury.

MONDAY, Feb. 6th.—2 P.M., Dr. Hinds Howell: patient Clinic. 3.30 P.M., Mr. Paton: Papilloedema

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Cli 3.30 P.M., Dr. Grainger Stewart: Principles Un lying the Diagnosis of Spinal Tumours (2).

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-pat Clinic. 3.30 P.M., Dr. Walshe: Neurosyphilis

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P Mr. Elmquist: Demonstration of Re-educa Methods.

HOSPITAL FOR SICK CHILDREN, Great Ormond-str W.C.

THURSDAY, Feb. 9th.—4 P.M., Mr. O. L. Addison: Cy scopy.

YAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, Feb. 7th.—3.15 P.M., Dr. A. Whitfield: Lichen Planus, Varieties and Treatment.
NTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, ray's Inn-road, W.C.
WEDNESDAY, Feb. 8th.—4 P.M., Consultations and Demonstrations.
FRIDAY.—4 P.M., Dr. Dan MacKenzie: Early Mastoid Operations.
PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Feb. 8th.—4.30 P.M., Mr. R. H. Jocelyn-Swan: Enlarged Prostate.
YAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-quare, W.C.
WEDNESDAY, Feb. 8th.—4.30 P.M., Dr. W. N. East: Some Problems of Forensic Psychiatry.
NDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 9, Leicester-square, W.C.
TUESDAY, Feb. 7th.—5 P.M., Dr. Graham Little: Lichen Planus.
THURSDAY.—5 P.M., Dr. J. E. M. Wigley: Lupus Erythematosus.
LGRAVE HOSPITAL FOR CHILDREN, Clapham-road, .W.
WEDNESDAY, Feb. 8th.—4.30 P.M., Dr. Norman H. Hill: Clinical Meeting.
OPLE'S LEAGUE OF HEALTH.
WEDNESDAY, Feb. 8th.—6 P.M. (at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, W.), Dr. R. D. Gillespie: Habit and Adaptation.
MARY'S HOSPITALS, MANCHESTER (Post-Graduate ecture).
FRIDAY, Feb. 10th.—4.30 P.M. (at the Whitworth-street West Branch), Dr. Bride: Obstetric Operations.
IVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Feb. 10th.—3.30 P.M., Dr. Yates: Clinical Cases.

Appointments.

FCHER, W. H., M.D. Oxf., D.P.H., has been appointed Medical Officer of Health, Godstone R.D.C.
RKE, EILEEN M., M.B., B.S. Lond., Medical Officer to the Nottingham Board of Guardians.
DISON, H. W., M.B., B.Chir. Camb., Medical Superintendent of Wonford House Mental Hospital, Exeter.
GG, R. A., M.D. Edin., D.P.H., County Medical Officer of Health for East Sussex.
ES, A. M., M.D., F.R.C.S. Edin., Honorary Surgeon to the Ear, Nose and Throat Department of Cardiff Royal Infirmary.
LEAN, J. ALLAN, M.B., Ch.B. Glasg., Assistant Surgeon, Dewsbury and District General Infirmary.
NSON, M., M.D., Ch.B. Glasg., D.P.H., Medical Officer of Health and School Medical Officer, Wood Green U.D.C.
SHALL, C. M., M.B., Ch.B. New Zealand, Resident Medical Officer to the Freemasons' Hospital and Nursing Home, Fulham-road, S.W.

Vacancies.

For further information refer to the advertisement columns.

Saints' Hospital for Genito-Urinary Diseases, 91, Finchley-road, N.W.—Hon. Consulting Phys. and Hon. Surg. Reg.
ford County Hospital.—Asst. H.S. At rate of £130.
ngbroke Hospital, Wandsworth Common S.W.—H.S. At rate of £120.
hton, Royal Sussex County Hospital.—H.S. £150.
tol General Hospital.—H.P., H.S., and Res. Obstet. O., &c. Each at rate of £80.
iff Royal Infirmary.—Hon. Asst. Surg. to Ear, Nose, and Throat Department.
isle, Cumberland Infirmary.—R.M.O. At rate of £155. Also Jun. H.S. At rate of £135.
of London Hospital for Diseases of Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
of London Maternity Hospital, City-road, E.C.—Asst. Res. M.O. At rate of £80.
don, Children's Medical Home, Waddon.—Visiting M.O. (V.D.). £150.
don County Borough.—Deputy M.O.H., &c. £780.
nshire County Council.—M.O. £600.
African Medical Service.—Sanitation Officer. £600.
Suffolk and Ipswich Hospital.—Cas. O. (Male). £150.
burgh Royal Infirmary, Ophth. Dept.—Sen. Clin. Asst. £145.
er, Royal Devon and Exeter Hospital.—Res. Cas. O. At rate of £100.
ge Town Municipality, Penang, Straits Settlements.—Deputy Municipal Health O. $7200.
t Yarmouth General Hospital.—H.S. £150.
dford Union Institution, Warren-road.—Res. Asst. M.O.
tford County Hospital.—Hon. Asst. S.
g-Kong Government.—Radiologist Electrologist. £740.
pital for Tropical Diseases, Endsleigh-gardens, W.C.—Hon. Asst. P.
vich, Heathfield Infirmary, &c.—Asst. Res. M.O. £250.
ester Royal Infirmary.—Hon. P. and Asst. Hon. P. Asst. Pathologist. £500.
isham, Metropolitan Borough of.—Asst. M.O.H., &c. £650.
Liverpool, Hospital for Consumption and Diseases of Chest.—Asst. M.O., &c. £150.
London School of Hygiene and Tropical Medicine, 23, Endsleigh-gardens, W.C.—University Chair of Biochemistry. £1300. Also Research Studentship in Protozoology. £250.
Manchester and Salford Hospital for Skin Diseases.—H.S. £100.
Middlesbrough County Borough.—Asst. to M.O.H. £450.
Ministry of Health, Whitehall, S.W.—M.O. £600.
Omdurman, C.M.S. Hospital.—Doctor required.
Preston County Borough.—Asst. S.M.O. £600.
Queen's Hospital for Children, Hackney-road, E.—Res. M.O. £200. Also Cas. O. At rate of £100.
Rochester, St. Bartholomew's Hospital.—H.P. At rate of £175.
Royal Free Hospital School of Medicine for Women.—University Chair of Pathology. £1000.
Royal Free Hospital and London School of Medicine for Women, Obstet. and Gynæcol. Unit.—Anæsthetist. £100.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—H.S. At rate of £150.
Royal National Orthopædic Hospital (Country Branch), Stanmore, Middlesex.—H.S. At rate of £150.
Royal Naval Dental Service.—Five Dental Surgeons.
Royal Northern Hospital, Holloway, N.—Ophth. Surg.
St. John's Hospital, Lewisham, S.E.—Asst. P.
St. Thomas's Hospital.—Phys. in charge of Out-patients.
Sleaford, Kesteven Mental Hospital.—Asst. M.O. £350.
Smethwick County Borough.—Asst. M.O.H., &c. £600.
Stoke-on-Trent, City of.—M.O. of Venereal Diseases Centre. £850.
Truro, Royal Cornwall Infirmary.—H.S. £170.
University College Hospital Medical School.—Radcliffe Crocker Travelling Scholarship in Dermatology. £280.
Warwick County Mental Hospital, Halton.—Asst. M.O. £300.
West London Hospital, Hammersmith-road, W.—Hon. Obstet. Reg.
West Riding County Council.—School Oculist. £600.
Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Lochaber District (Sheriffdom of Inverness, Elgin, and Nairn). Applications should reach the Private Secretary, Scottish Office, Whitehall, London, S.W., not later than Feb. 15th.

Births, Marriages, and Deaths.

BIRTHS.

BREWERTON.—On Jan. 24th, at Harley-street, W., the wife of Elmore Wright Brewerton, F.R.C.S., of a son.
YEOMAN.—On Jan. 25th, at White Croft, Fetcham Park, Leatherhead, the wife of J. Clark Yeoman, L.D.S., of a son.

MARRIAGES.

CAMPBELL—STANSFIELD.—On Jan. 25th, at the Parish Church, East Hoathly, by the Rector, the Rev. J. F. Groves, M.A., Angus Henry Campbell, M.B., Ch.B. Edin., B.Sc., D.P.H., only son of the late Alexander Campbell and of Mrs. W. M. Campbell, of Edinburgh, to Helen Lucy, younger daughter of Mr. and Mrs. J. E. Stansfield, of Caburn, Halland, Sussex.
FINLAYSON—LAWSON.—On Jan. 25th, 1928, at the Cathedral Calcutta, John Taylor Finlayson, elder son of the late J. H. Finlayson and of Mrs. Finlayson, of Kingswood, Surrey, to Miriam Lawson, M.R.C.S., L.R.C.P., only daughter of the late Dr. H. A. Lawson and of Mrs. E. Lawson, of Celci, Epping.
MOSS—EDGE.—On Jan. 26th, at St. Gregory's Church, Cheltenham, Dr. Leslie Newell Moss, of Ipswich, to Hilda Mary Cécile, elder daughter of R. C. Edge, late P.W.D., India, and Mrs. Edge.

DEATHS.

BRAMWELL.—On Jan. 19th, of pneumonia, Hugh Ransom Bramwell, M.B., in his 66th year.
MILLIGAN.—On Jan. 25th, at Cheyne-walk, Northampton, Robert Arthur Milligan, M.D., M.R.C.S., L.R.C.P., aged 69 years.
WEBSTER.—On Jan. 26th, at Inverkip, Ryde, I.O.W., Lieut.-Colonel C. G. Webster, F.R.C.S. Edin., I.M.S. (retired), aged 56.
WILSON.—On Jan. 12th, at Rollestone, Southbourne, Bournemouth, R. O. Murray Wilson, M.R.C.S. Eng., L.R.C.P. Lond.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. II., 1927.

THE Index and Title-page to Vol. II., 1927, which was completed with the issue of Dec. 31st, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

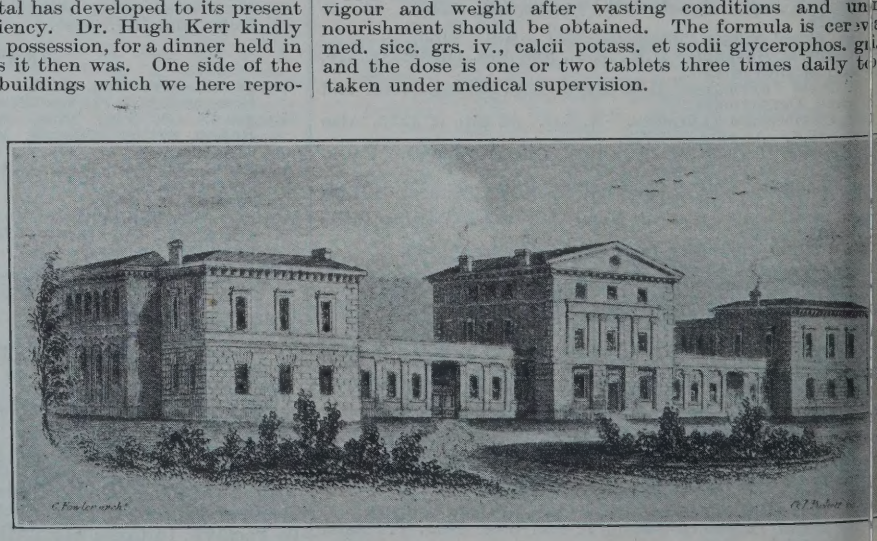
Notes, Comments, and Abstracts.

VILLEMIN AND THE ELIMINATION OF TUBERCLE.

Jean-Antoine Villemin, professor in the Army Medical School of Val-de-Grâce, was the first to prove (in 1860–61) that tubercle was spread by infection, and to propose reasoned measures for its prevention. The centenary of his birth was celebrated in Paris last October, as our correspondent then noted (THE LANCET, 1927, ii., 1257), and a fuller account is now given in the *Archives de Médicine et de Pharmacie Militaires*. Among the guests were Sir Matthew Fell and Major Voncken, President and Secretary respectively of the Committee of the International Association of Military Surgeons, whose fifth congress will take place in London next year, under General Fell's presidency. Prof. A. Calmette, who presided over the scientific meeting at the Val-de-Grâce, said that, as a recent example of Villemin's teaching, over 48,000 French children had been rendered immune to tuberculosis by B.C.G. vaccine, given by the mouth in the first fortnight of life, during which the intestines are permeable to the bacilli. Similar protection was now being given subcutaneously to older children, and he called attention to the experiment of inoculating 200 nurses in training at Oslo for tuberculosis work. Dr. Rousseau, of the Medical Service of the Colonial Army, said that in Indo-China 20,000 infants had been inoculated with B.C.G., and over 800 in Senegal. Dr. Grosfillez, of the same Service, said that in 1923 the phthisis death-rate of "native" troops employed in France was, for Senegalese, 14 per 1000; for Malagasy, 6·6; for men from Indo-China, 10. Active measures were taken, and half of the detachments of 1925 were protected by B.C.G.; this year the inoculation will be repeated for the Senegalese, and the results minutely examined. Figures are not available, but the results so far are considered encouraging. For the prevention of tuberculosis in the Navy, a matter which is giving the authorities some concern, Surgeon-Captain Gazamian proposed that no one should be allowed on board with open tuberculosis, while doubtful cases should be carefully watched, and, if necessary, eliminated. Some people, he said, laugh at such proposals—"the Navy is not a pre-tuberculous colony"—but to neglect them costs the public dear. Men who work within the armour should sleep in the open air, at any rate in peace-time, although (be it noted) the paymaster's staff and the telegraphists who live high up have more tubercle than the engine-room staff in the depths. Food and clothing are now good on French ships, personal cleanliness is easy, and antituberculous propaganda assiduously pushed in films, lectures, tracts, and by games. Fonssagrives, the great French naval hygienist of 1860, said that disaster came to the ship whose men did not sing. The incidence of phthisis had dropped from 12·5 per 1000 in 1900 to 5 in 1920–26, but still compared unfavourably with 2·7 (2·24 in 1924) in the English, and 2·85 in the United States Navy.

THE LONDON FEVER HOSPITAL.

THE death of Sir Mackenzie Chalmers, recently noted in our columns (Jan. 21st, p. 142), was a reminder of the London Fever Hospital as it is, for it was largely owing to his untiring effort that the hospital has developed to its present level of equipment and efficiency. Dr. Hugh Kerr kindly sends us a ticket, now in his possession, for a dinner held in 1850 in aid of the hospital as it then was. One side of the ticket gives the view of the buildings which we here reproduce, whilst the other states that a public dinner for the benefit of the London Fever Hospital (Patron, H.R.H. Prince Albert) will take place at the Freemasons' Tavern on Tuesday, May 14th, 1850, the Right Hon. the Earl of Devon, President, in the chair. The stewards were to be His Grace the Duke of Buccleuch, the Earl of Carlisle, Lord Robert Grosvenor, Lord Ashley, the Master of the Temple, W. A. Anderson, Esq., J. A. Bostock, Esq., Dr. Bushnan, R. H. Coote, Esq., Thomas Corney, Esq., Dr. C. J. Cox, the Rev. Dr. Cumming, Richard Davis, Esq., W. T. Dyer, Esq., W. Everett, Esq., Henry Hyde, Esq., Dr. Jones, Dr. Jenner, V... Lawrence, Esq., J. L. Mallett, Esq., Dr. Roget, ... Rev. Edward Scobell, Dr. Southwood Smith, San... Turner, Esq., Henry Wakefield, Esq., John Ashton Ya... Esq., and James Yates, Esq. The ticket, whose p... was one guinea, is signed by the secretary, Charles H... of 33, Ely-place; it bears the number 329, and conclu... with a statement that dinner will be on the table ... half-past 5 o'clock.



The London Fever Hospital, Liverpool-road, Islington, as it was in 1850.

LETTERS TO YOUNG DOG OWNERS.

A Record

OF

FIFTY CONSECUTIVE CASES OF PREGNANCY AND PARTURITION IN PATIENTS WITH CRIPPLED HEARTS.

A Paper read at Liverpool Medical Institution.

BY JOHN HAY, D.L., M.D. LIVERP., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, LIVERPOOL UNIVERSITY; SENIOR PHYSICIAN AND PHYSICIAN IN CHARGE OF HEART DEPARTMENT, LIVERPOOL ROYAL INFIRMARY; CONSULTING PHYSICIAN TO LIVERPOOL MATERNITY HOSPITAL;

AND

ELIZABETH HUNT, M.D. LIVERP.,
LATE SAMUELS RESEARCH SCHOLAR; LATE CLINICAL ASSISTANT TO THE HEART DEPARTMENT OF THE ROYAL INFIRMARY.

OUR object is to correlate the difficulties and dangers of pregnancy and labour with the disadvantages and disabilities of valvular disease of the heart. For the last five years we have watched and kept records of pregnant women suffering from valvular disease who have passed through our rest home and maternity hospital. In many instances they have subsequently been kept under observation at the Heart Clinic of the Royal Infirmary. We have also discussed with colleagues in the maternity hospital the various difficulties and problems as they presented themselves. It is more than probable that the type of case met with in the rest home and maternity hospital, and on which this record is based, is on the whole of a more serious nature than the average type of case.

Various Practical Problems.

The problem is one of considerable practical importance and confronts us in various ways: 1. Is marriage advisable in the presence of a crippled heart, appreciated either by valvular disease or by gross arrhythmia? 2. Should a pregnancy be terminated or allowed to go to full term? 3. If it is to be terminated, when and how? 4. If to full term, what can be done to help the heart during the stress of labour? 5. After the birth of the child how is the patient to be managed?

Pregnancy and labour, even under normal conditions, place the heart under strain. It is essential that we should fully appreciate the nature of this strain when considering the reaction of a crippled heart to pregnancy. The circulation is embarrassed in three ways: 1. The weight of the patient increases. The work of the heart varies with the weight of the individual. 2. The placenta, the large uterus with hugely dilated vessels, the growing breasts, all make extra demands on the maternal heart. 3. The large uterine tumour after the sixth month interferes with the movements of the diaphragm; there are changes in the shape of the chest; the circumference increases; the costal angle widens; the heart is pushed up and out. In later months the bases of the lungs are compressed. Pressure shows itself in varicose veins, piles, and œdema.

Many of these effects are more noticeable in a primigravida, and there is gradual increase in the difficulties and discomforts as pregnancy advances. The crucial test, however, is the hour of deliverance.

The period of dilatation, from the commencement of labour until the cervix is completely dilated, does not put a severe strain on the heart, although the pains may cause a condition of general exhaustion, especially if the first stage is unduly prolonged. There is both general and nervous exhaustion, and pain, fatigue, and sleeplessness are the detrimental factors.

The period of expulsion, from complete dilatation of the cervix until the birth of the child, is the important phase. With each pain the patient braces her body, gets her feet against something solid, takes a deep inspiration, closes the glottis, and makes forcible straining movements with the abdominal and respiratory muscles, accompanied by a grunt. Her face becomes congested and may be covered with sweat. In a patient with valvular disease cyanosis is frequent. As the pain subsides the glottis is opened and respiration re-established. During each pain the arterial blood pressure is raised and the heart quickens. Prolongation of this stage may cause very great physical and cardiac exhaustion.

Between the birth of the child and the birth of the placenta there is a sudden drop in the blood pressure. The patient may collapse and there may be severe hæmorrhage.

I think it will be readily admitted that pregnancy and labour do throw a definite strain on the heart, a strain which may be very great if labour is unduly prolonged, and in which the reserve power of the heart is called upon to meet the stress. The crippled heart is less equal to meet this severe call on its powers. Three points must be remembered: 1. In rheumatic valvular disease the myocardium is probably damaged as well as the valves. 2. In mitral stenosis, the commonest lesion: (*a*) the output of blood per minute is considerably diminished, and is probably not more than 2 to 5 litres; (*b*) there is persistent engorgement of the alveolar walls, and an engorged alveolar wall is inelastic; (*c*) there is frequently emphysema, especially in the long-standing cases, with the inevitable dependence on free movement of the diaphragm. 3. Auricular fibrillation is a grave handicap to any heart and a very serious additional load in pregnancy and labour. It is probably the most disastrous of all the cardiac disabilities in labour.

Bearing these facts in mind it is clear that in pregnancy and parturition there is an increased liability to cardiac failure, and it is this liability which has to be met and diminished by careful supervision and treatment.

Evidences of Cardiac Failure.

A mild degree of *dyspnœa* is usually a feature of the last month or two of every pregnancy. In cardiac cases it manifests itself earlier, especially in those with emphysema. It may become excessive, preventing recumbency and interfering with sleep.

Pain is not common, but there may be an ache over the cardiac thrust.

Œdema of the bases of the lungs is suggestive of commencing cardiac failure.

A steady increase in pulse-rate, progressive venous engorgement and cyanosis are clear and important danger signals.

The extent and severity of symptoms must be the guide to management.

Table I. shows the very large preponderance patients suffering from mitral stenosis.

TABLE I.—*Classification of Cases.*

Congenital heart	1
Mitral stenosis—	
Moderate degree	20
Advanced degree	15
Mitral stenosis and aortic regurgitation	7
Aortic regurgitation	2
Auricular fibrillation—	
With advanced mitral stenosis	4
" " and aortic regurgitation	1
Total	50

Of these: Primipara, 13; deaths, 3. Multipara, 37; deaths, 2.

TABLE II.—*Ætiology: In 26 Cases of V.D.H. in Pregnancy.*

	Age at onset.	No.	
Chorea	8 to 20	9	21
Chorea and rheumatic fever	8 to 15	3	
Rheumatic fever	15 to 25	3	
Rheumatic pains	11 to 16	3	
Growing pains and sore-throats	—	2	
Acute rheumatism	26	1	
Scarlet fever	12	1	
Scarlet fever and muscular rheumatism	6	1	
Scarlet fever and growing pains	—	1	
No history of any illness	—	2	

The ætiology was carefully investigated in 26 patients, and was interesting from the cardiological

point of view. It demonstrated the preponderance of chorea and rheumatism as the primary cause of valvular disease. In several instances there were acute rheumatic manifestations after parturition.

The Frequency of Hæmoptysis.

We noted a peculiar liability to hæmoptysis among pregnant women, and our records showed that it occurred in 30 per cent. Of the 38 cases of mitral stenosis 11 suffered from hæmoptysis; of 8 cases of mitral stenosis and aortic regurgitation 2 suffered from hæmoptysis; while 2 out of the 4 cases of auricular fibrillation combined with mitral stenosis suffered from hæmoptysis. It is noteworthy that the tendency is for the hæmoptysis to occur in the earlier months of pregnancy, before the uterine condition can be said to have interfered mechanically with the circulation. Records of 75 non-pregnant patients suffering from mitral stenosis in the wards of the Royal Infirmary showed that the incidence of hæmoptysis in this series was 22·7 per cent. Cowan and Ritchie give 17·6 per cent. for hæmoptysis in cases of mitral stenosis. Table III. gives details of these 75 patients.

TABLE III.

—	No.	Hæmoptysis.	Remarks.
Mitral stenosis	25	6	Three of the 6 cases were admitted with acute cardiac failure, dropsy, &c. One had subacute infective endocarditis.
Mitral stenosis and aortic regurgitation.	9	3	One of the 3 died of subacute infective endocarditis, and in 1 there was terminal thrombosis of right jugular vein.
Auricular fibrillation and mitral stenosis.	41	8	Four of the 8 were admitted with acute cardiac failure. Another died. In a sixth X rays reported T.B., but no T.B. was found.

It is obvious that in this series the cardiac disease was graver in type than that found in the pregnancy series, so that I think there can be no doubt that we have a definite predisposition to hæmoptysis among pregnant women with mitral stenosis.

Auricular Fibrillation.

Auricular fibrillation does not in itself justify induction until specific treatment with digitalis has been given a full trial and has failed. In this series there are five patients in whom fibrillation was present, with one death—a death not due primarily to the cardiac condition, but to the associated grave kidney disease. In this woman induction was performed at 36 weeks and the patient died of uræmia. In the remaining four labour was normal, precipitate in one, and premature in another. All were patients suffering from advanced mitral stenosis, and had been under careful supervision and treatment during the later months of pregnancy, and I have no hesitation in saying that it was to this that they owed their lives.

In one of the four full doses of digitalis had steadied the heart and everything was progressing favourably until the patient returned home and ceased taking any medicine for nine days. She returned to the maternity hospital with the onset of labour, in great cardiac distress with a heart-rate between 140 and 150. She received great benefit from the intravenous injection of strophanthin, which acted with sufficient rapidity to control the heart before the onset of the second stage.

Dr. Leyland Robinson recently reported the deaths of four patients admitted urgently for delivery, suffering from auricular fibrillation that had received no treatment previous to admission. This indicates the increased risk to life when untreated auricular fibrillation is present. He later [1] reported 18 cases of pregnancy complicated by auricular fibrillation, which had not received adequate antenatal care. Many of them were frankly emergencies. Of these 13 died and, with two exceptions, death was immediately related to labour. Herrick [2] records three patients w valvular disease and auricular fibrillation in a se of 40 patients; one had a normal labour, and in t he procured therapeutic abortion at the second third months respectively. The outlook in patie suffering from auricular fibrillation depends on results of specific treatment with full doses of digita and the careful supervision of the terminal month pregnancy, and assistance during the second stag labour. It depends also on the degree to which fibrillation is distressing and handicapping the he In this hearts vary. As soon as the child is viable sign of progressive cardiac failure justifies interventi

Termination of Pregnancy: Induction v. *Cæsarea Section.*

This raises the question of the relative value induction and Cæsarean section. In Table patients are classified according to the nature of termination of pregnancy.

It is not easy to determine the relative valu induction and Cæsarean section, and each case to be decided on its merits. The first aim is to en the uterus with the least strain to the mother's he the second is to obtain a living child when poss even by a post-mortem Cæsarean section. I Blair Bell emphasised the following points:—

1. "All other things being equal, induction of labo a less severe procedure than Cæsarean section.

2. If there is any considerable degree of contractio the pelvis Cæsarean section should be considered: (*a*) the point of view of the child; (*b*) from the point of of long and difficult labour even after induction.

3. Induction should be practised three to four w before the expected date of parturition, if the full be is to be obtained for the mother.

4. A grave difficulty arises in the presence of a brea compensation associated with œdema. Both proce become more grave, and it might be necessary to put induction, because of the extensive œdema of the v In these circumstances one might be compelled to Cæsarean section with spinal anæsthesia.

These are, of course, general remarks; every case mu considered absolutely on its own merits; fatness, thin multiparity, and so on, influence the decision."

Bellingham Smith,[3] of Guy's, comparing the dan of induction with those of labour, says:—

"Induction, if anything, is a more serious trial labour at term, and I hold the view that those patients would survive induction would pass equally well thr labour at full time, and that those who appeared like die in the course of labour were equally as likely to d the result of induction."

The matron of the maternity hospital, who has a very wide experience, has been impressed by easy labour following induction in most ca patients. The actual strain to the mother is prob less with a Cæsarean section, but there is gr distress and discomfort during the subsequent or ten days. The convalescence is not infrequ painful and the sleep disturbed. On the other h Cæsarean section saves the heart from the stra the second stage of labour with its obvious risks

[1] THE LANCET, 1927, i., 170.

[2] Amer. Jour. of Obstet. and Gynecol., 1922, iv., 83.

[3] Brit. Med. Jour., 1925, i., 442.

desirable the woman can be sterilised. This is sometimes deferred to the second Cæsarean section. My impression is that the induction of labour is the wiser course unless there is a clear indication that, from any cause, labour is likely to be long and difficult and the viability of the child is in question. It is generally agreed that induction is more easily induced and less of a trial in a multipara than in a primigravida. If Cæsarean section is carried out under general anæsthesia there is the danger of subsequent vomiting and of bronchitis or broncho-pneumonia—serious complications in a patient with advanced mitral stenosis. Fortunately spinal anæsthesia can be used to obviate the risk. The best general anæsthetic is ether or ethanesal as a vapour, warmed by Shipway's apparatus and accompanied by oxygen.

The Fatal Cases.

In this series of 50 consecutive cases there are five deaths, and it was a little disturbing that the first and second patients in the series both died. It is significant that there was no death from acute cardiac failure of the ordinary type during or immediately after labour. A short epitome is given below of the five fatal cases.

CASE 1.—Aged 24; multipara. Advanced mitral stenosis. Large heart. Left rest home after five weeks treatment, free from œdema. Five days later, normal labour, eight months' child. On tenth day got up and œdema returned. Death 24 days after labour. Cause unknown.

CASE 2.—Aged 30; multipara. Mitral stenosis and aortic regurgitation. Fifty-four days before labour sudden onset of auricular fibrillation followed by acute cardiac distress. Temporarily controlled by intravenous strophanthin and digitalis. Signs of nephritis. Condition became critical. Induction thirty-second week. Anuria and death from uræmia 0 hours after delivery. Autopsy: "Large white kidney."

CASE 32.—Aged 35; primipara. Advanced mitral stenosis; slight regurgitation. Parenchymatous nephritis. Cæsarean section at 31 weeks. Died three days later, comatose; uræmia.

CASE 46.—Aged 21; primipara. Advanced mitral stenosis; slight regurgitation. Clinical signs of nephritis, slight and atypical. Died suddenly undelivered at 36 weeks from acute pulmonary œdema. Autopsy: "Acute parenchymatous nephritis."

CASE 48.—Aged 29; primipara. Advanced mitral stenosis. Premature labour at 34 weeks. Clinical signs of acute parenchymatous nephritis more marked after labour. On eighth day insisted on leaving hospital. Died thirteenth day after parturition.

There was no evidence of nephritis in the earlier stages of pregnancy. An autopsy was obtained in two of the four patients and, in the opinion of the pathologist, the nephritis was of recent origin.

Damaged Kidneys.

The toxic albuminuria of pregnancy sometimes proceeds to marked degeneration or even necrosis of the renal parenchyma. There is also the "nephritic toxæmia" of pregnancy, which may be the result of the deleterious toxic effects of pregnancy upon a kidney already pathological. In such patients the symptoms appear early in the pregnancy. The four patients in our series do not conform to either of these groups. Nor do they, in the details of their symptomatology, fall accurately into line with the usual examples of acute or subacute parenchymatous nephritis. It would appear that a woman with advanced mitral disease is liable to develop an atypical form of parenchymatous nephritis as a result of pregnancy, and that this manifests itself late in pregnancy and greatly increases the gravity of the outlook. It is significant that in four of the five fatal cases there was grave kidney damage, and I have no doubt that this rather than the valvular disease was the determining factor responsible for death. The combination of mitral stenosis with chronic nephritis is well known, and is more common in women than men. Pregnancy may be the determining factor in this preponderance.

Management after Labour.

Pregnancy and parturition cause less permanent damage than one would expect. It is remarkable how satisfactorily most cardiac patients progress after labour is past, if they have been carefully piloted through the difficulties and adequately treated before, during, and after labour.

Unassisted labour at full term in a decompensated heart (even if the patient survives) will probably leave the heart permanently less efficient. Patients with advanced aortic regurgitation are especially liable to suffer, but moderate grades of aortic regurgitation with a good myocardium tolerate labour well.

Since there is, after labour, a risk of permanent depreciation of the heart muscle, great care should be taken to enable the myocardium to recover fully before allowing the patient to return to the ordinary stress of life. A long period of rest must be enforced. Any anæmia should receive prompt and adequate treatment.

It is not unusual for a woman to put on weight rapidly after the birth of a child. For this there are probably several reasons, one of which is a condition of hypopituitarism, which may result from the over-activity of the pituitary during pregnancy. This increase in weight is a real danger to a woman with a damaged heart. Obesity must be prevented or treated, for as everyone knows, the work of the heart bears a definite relationship to the weight of the body.

In our experience there is no valid objection to lactation; in fact our patients appeared to do better when suckling. The artificial feeding of a child entails more labour and strain on a heart than the normal method.

Survey of General Conduct.

Pregnant women with diseased hearts must be treated primarily as cardiac patients, and the first indications of cardiac failure noted. They must be under regular medical supervision throughout. Among the poor an antenatal clinic and a rest home are of the very greatest value. In every patient the reserve power of the heart must be increased by adequate rest and symptomatic treatment. Rest is essential, more especially in the four to six weeks before labour. Dyspepsia, flatulency, constipation, insomnia, bronchitis, and other discomforts must be remedied. If there is auricular fibrillation it must be controlled with digitalis and the optimum dose found and maintained. Any woman with auricular fibrillation must be kept under constant supervision.

During labour the aim is to lessen the nervous and physical exhaustion of the first stage and to diminish the physical strain of the second stage. Light anæsthesia during the second stage is helpful, and narcotics are valuable; they reduce the voluntary effort. An early resort to instrumental help is most important.

In the earlier months cardiac failure which refuses to respond to treatment justifies immediate intervention, especially if there be persistent retching and vomiting. At times there is a peculiar and unexplained cardiac failure in earlier months—certainly not due to mechanical causes—which resists treatment and is only relieved by terminating the pregnancy. Induction, however, should never be attempted until compensation has been restored as far as possible by rest and drugs. The stress of labour is likely to prove fatal to a woman whose heart is already struggling with difficulty to maintain the circulation.

Experience has shown that the majority of women with crippled hearts, in whom the cardiac reserve is good, are capable of pregnancy and labour without any great additional risk. This is especially true if the cardiac lesion is not progressive and if there is no history of a previous cardiac breakdown. There is admittedly an increased risk, but it is one that many women are prepared to take and which is not unreasonable under constant supervision. In multiparæ a knowledge of the manner in which the previous pregnancy was tolerated is an excellent guide.

Veto on Child-bearing.

The mere presence of mitral stenosis or even aortic regurgitation, the occurrence of premature beats, the existence of cardiac pain and tenderness over the cardiac thrust, and the presence of cardio-respiratory bruits, do not in themselves justify a childless

marriage. So long as the cardiac reserve is good, so long as the response to effort is satisfactory and there is no undue enlargement of the heart, the presence of valvular disease is no bar either to marriage or pregnancy. When, however, there is a clear history of cardiac failure and distress during a previous pregnancy, and if it is known that after labour convalescence was unduly prolonged, owing to cardiac weakness, then a definite veto must be given. Such a decision is all the more imperative if the cardiac distress had increased as pregnancy progressed and become urgent and alarming during the act of parturition.

The same opinion is justifiable in cases with auricular fibrillation; advanced mitral stenosis, as shown by a large heart, a long diastolic bruit, and small cardiac reserve; and advanced aortic regurgitation with a big heart, Corrigan's pulse, and defective reserve.

It is the borderland cases that present the greatest difficulty. In them any abnormality in the pelvis likely to prolong labour becomes of very great importance.

A pregnant woman who is aware of her cardiac disability should be reassured. Too often the risks are unduly stressed, and her pregnancy is overclouded by fear and apprehension—an apprehension frequently aggravated and intensified by a fussy spouse. The necessity for careful supervision must be emphasised, and the importance of rest and sensible behaviour discussed with her quite freely. Motherhood is woman's peculiar privilege and prerogative, a privilege which we have no right to refuse her without adequate reason.

Pregnancy inevitably entails certain risks, which a woman accepts in order that she may have a child. A crippled heart is an added risk, and it may be an unjustifiable risk. But the more I have studied these patients the more I have been impressed with the wonderful manner in which their hearts have responded to care and treatment during pregnancy. I believe that a woman with valvular disease is entitled to know to what extent the normal dangers of pregnancy are increased by her cardiac lesion, and if she is prepared to face the ordeal, then we must do all we can (and we can do a very great deal) to minimise the dangers of pregnancy and parturition by constant supervision and prompt and efficient treatment—both medical and surgical.

A CRITICAL EXAMINATION OF SOME CASES OF A SCARLATINIFORM TYPE.*

BY G. E. FRIEND, M.A. OXF., M.R.C.S. ENG.,
MEDICAL OFFICER, CHRIST'S HOSPITAL.

Historical.

To Sydenham is due the differentiation of scarlet fever from morbilli, and only comparatively recently has rubella been recognised as a distinct disease; as late as 1895 Donald Hood, among others, inclined to the view that rubella as a separate entity did not exist. In 1884 Filatow observed an epidemic in one family which he thought was an abnormal form of scarlet fever, and told the parents that their children would, as a consequence, be protected against this disease. But in 1885 scarlet fever attacked three of the children who had been affected in the previous epidemic. He then described, under the name of scarlatiniform rubella, an infectious disease, acute, contagious and epidemic, characterised by a scarlatiniform rash, but distinguished by the mildness of its course and other peculiarities. In 1886 he abandoned this view and thought he had to deal with an ordinary rubella with a polymorphic rash, but later still he inclined to the view, formulated by Lebert in 1851, that morbilliform rubella and scarlatiniform rubella should be considered two distinct diseases. In 1894 Dukes published an instructive paper on the features which distinguish epidemic roseola (roserash) from measles and from scarlet fever. In 1900 he published in THE LANCET his paper on the fourth disease.[1] In 1901 Weaver (M.O.H., for Southport) in a paper published in the Dublin *Journal of Medical Science*,[2] described several cases occurring in the Borough Fever Hospital in 1900.

In THE LANCET (1900, ii., 289) Sir William Broadbent stated that he accepted "without hesitation the differentiation of rubella into two distinct diseases which Dr. Clement Dukes has made." Drs. Kidd and Romer also supported this view, while abroad Trammer, Bokai, Ruhemann, Unruh, Ardin Delteil and Chenisse all reported epidemics resembling Filatow-Dukes disease. My own experience of some 73 cases fully agrees with the accounts published by Dukes and Weaver, and, as far as it goes, the description given by Filatow, and I am convinced that these cases are not aberrant forms of either scarlet fever or rubella. Dr. H. Aldersmith, my predecessor at Christ's Hospital for 44 years, saw several small epidemics and was definitely of the opinion that Dukes was right. On the other side, in most modern text-books, fourth disease is usually only alluded to when discussing the differential diagnosis of scarlet fever and rubella. J. D. Rolleston, in his book published in 1925,[3] gives an account of it under its own name, but sums up against it as a separate entity. Prof. Teissier, of the Paris Faculty of Medicine, gives a good account of the discussions that had arisen around it in his book on infectious diseases published in 1922,[4] but sums up against Dukes, though he makes no mention of any personal experience of the disease.

In favour of the separate entity many authorities state that the diagnosis of rubella is often difficult owing to the variety of type of rash or to the indefinity of incubation, while the Code of Infectious Diseases in Public Schools, first published in 1889 by the Medical Officers of Schools Association, has in all its eight editions stressed the difficulty of diagnosis in scarlet fever.

In January, 1920, Dr. C. R. Box[5] wrote to THE LANCET describing certain cases which were then being sent to the London Fever Hospital as scarlet fever, but which were in his opinion atypical, and contrasted these cases with those described by Dukes as fourth disease. His letter was headed, Is there a Para-scarlet Fever? A short correspondence ensued from this letter which neither advanced nor disproved the thesis. On August 19th, 1922, Dr. F. Simpson,[6] in an article in THE LANCET, described a series of cases admitted to the Croydon Borough Hospital. Fifteen cases occurred in a diphtheria ward, apparently from a convalescent diphtheria patient who was found to be desquamating, and about the same time thirteen or more cases were discovered among the admissions to the scarlet fever wards. He gave the apparent incubation among the diphtheria patients as "about three days," but otherwise his description of the symptoms and the rash agrees practically word for word with my records of the cases I have called para-scarlet A. For the sake of brevity I have drawn up a table of different diagnosis for morbilli, scarlet fever, para-scarlet A and B and rubella. He concludes with these words:—

"There would seem, finally, little or no justification for including the above series of cases as falling within the province of rubella any more than within the hazy and ill-defined boundaries of a so-called fourth disease, while the distinctness of the type from ordinary scarlet fever is practically certain. Although it is not pretended that the foregoing remarks are at all exhaustive of the several exanthematous conditions which have from time to time been described under the name of a fourth disease, it yet seems justifiable to conclude that mild scarlet fever, possibly and as suggested of the nature of a para infection, may be responsible for many instances of an exanthematous outbreak resembling scarlet fever but described as a 'fourth infection.'"

In THE LANCET (1923, i., 950) there appeared an article by Dr. H. M. Raven,[7] describing a series of 12 cases which occurred in a school of 80 girls and staff, as an epidemic of fourth disease, with which diagnosis I was inclined to agree when I first read his

* A paper read before the Fever Group of the Society of Medical Officers of Health on Nov. 25th, 1927.

article in MSS., but on re-reading it in print I am bound to confess that the evidence seems to favour very decidedly the diagnosis of scarlet fever. The occurrence of albuminuria and secondary enlarged glands, and especially the fact that the second batch of cases occurred six days after the return of the maid (who had tonsillitis seven days before the first batch) from sick leave, is strongly suggestive of scarlet fever. On the other hand, three of the staff subsequently developed the disease 18–20 days after the second batch of girls, and another girl was taken ill at home 20 days after the first batch and diagnosed independently as mild rubella. The case can undoubtedly be argued either way without the possibility of a definite conclusion.

The historical ground, therefore, proves that I do not need an excuse for the subject of this paper. Indeed, I think that when the clinical facts of the fourth disease are fully and fairly considered there is ground for maintaining that it is a separate disease, and I suggest that there are probably two forms of this pseudo-scarlet fever, and that when all the facts are considered they will be found to be to scarlet fever what the para-typhoids are to enteric fever.

Experience at Christ's Hospital.

During the 14 years I have been medical officer to Christ's Hospital Boys' School at Horsham I have seen and treated about 1200 cases in which rashes of a morbilliform or scarlatiniform type were present. 1044 of these were definite cases of exanthem, and the remainder include food or drug rashes, urticarias, and eczemas. Before 1916 I was familiar with Dr. Clement Dukes's description of fourth disease, but had never to my knowledge seen a case.

Between September, 1913, and March, 1916, there occurred at Christ's Hospital six cases of definite scarlet fever in two batches of five and one respectively; one batch of six cases of doubtful rubella, and 109 cases of definite rubella in six batches, the largest being an epidemic of 82 cases in the summer of 1915, when also the single case of scarlet fever occurred. There were also 15 cases of rubella, coincident with five cases of scarlet fever in the Lent term of 1915. With these exceptions all the cases occurred in small batches, presented no difficulties in diagnosis, and were easily stopped by early isolation, thorough disinfection, and the tracing of contacts where possible. Up to this date no rationing of food had come into force, and the outbreaks of exanthemata in the training camps all over the country did not start on any large scale until late in 1915 or early in 1916.

In the epidemic of 82 cases of rubella in the summer of 1915 I was struck by the fact that many rashes were erythematous from the start and never papular, and that none of the patients was ill in proportion to the amount of rash. As a rash of this type is described as the third variety of rubella rash I accepted them as such, though clinically some of the cases rather resembled mild scarlet fever. The incubation periods were unknown.

In the summer of 1916, however, a big epidemic of 204 cases occurred. This started at the beginning of term as ordinary rubella, and went on as a mixed epidemic of rubella, scarlet fever, and what I regarded then as fourth disease, to which I propose to allude below as para-scarlet A. In this epidemic, also, the incubation periods were difficult to make out, owing to the numbers and cross-infections which at first were unavoidable. According to my classification the cases were as follows:—

11 scarlet fever with	1	death, and	0	other cases of complication
45 para-S.F.A.	„ 1	„	8	
148 rubella	„ 0	„	0	

—i.e., a total of 204 cases with a mortality of 1 per cent, or 5 scarlatiniform cases with a mortality of 4 per cent.

There were no cases of cross-infection between scarlet fever and para-scarlet A. Two boys developed scarlet fever five and six days after admission with rubella, both probably, but not certainly, by cross-infection. Two boys developed para-scarlet A 15 and 34 days after admission with rubella. There was no possibility of cross-infection in either case. The first might have been infected with para-scarlet A just before admission, but the second must have been infected after admission, and it is to be noted that he developed para-scarlet A 15 days after the last definite case of scarlet fever.

Of	11	scarlet fever cases	none	gave a previous history of	scarlet fever or rubella.
„	45	para-scarlet	3	gave a history of recent	rubella.
„	45	„	3	„ „ „	scarlet fever.
„	148	rubella	1	„ „ „	rubella.
„	148	„	4	„ „ „	scarlet fever.

Dr. F. A. Juckes, of Horsham, and Dr. Rawdon Wood, then acting M.O.H., saw several of these cases of para-scarlet A, and both agreed that they were not at all typical scarlet fever cases. The latter told me that he had had two outbreaks with similar cases among troops near Brighton that year. Other cases were reported at Aldershot.

The following term there were five isolated cases of para-scarlet. The first occurred eight days after the school returned, and I am satisfied that infection was acquired during the holidays, but there was one boy isolated in the infirmary from the epidemic of the term before. There was no possible direct contact with him, and indirect contact was practically out of the question, as he had his own nurse and was on the top floor of the building, and the new case had not visited the infirmary before coming over with para-scarlet. I mention this as it will be noticed that the cases of para-scarlet occur in three groups, each group involving two consecutive terms. In the winter 1920—Lent, 1921, group the second batch occurred two months after term had begun. Although in the Lent-summer, 1922, group the second batch began with a case seven days after the beginning of term, and the four cases the previous term occurred at the end of term, if the house incidence and class contacts are ruled out, as they can be, there is no reasonable doubt that this too is an infection acquired during the holidays and not a reinfection at the school.

From the winter term of 1916 to the winter term of 1920 there were no cases of scarlet fever or para-scarlet, since when there has been one epidemic of scarlet fever with 15 cases, and four small outbreaks of para-scarlet A. There has been one large epidemic of rubella since the Lent term 1917. The two epidemics described below illustrate the importance of the incubation period and the difficulty of diagnosing a severe and fully developed case of para-scarlet from scarlet fever.

Winter, 1922.—Fifteen cases of mild scarlet fever, except that one boy had simple endocarditis. There were definite contacts in each case, the longest incubation being six days. The epidemic began from a boy who proved to be a carrier after a mild unrecognised attack during the holidays. He infected three boys after being back at school 15 days. The first case came in on Sept. 29th, just 15 days after the beginning of term. His was a very mild infection, and the possibility of a 15-day incubation made the diagnosis between mild scarlet fever and para-scarlet A difficult, until another case occurred, as his rash was fully out on admission. Two more boys from the same house came in on Oct. 4th (six days later), also very mild in type. The same evening I examined every boy in the house and found that the monitor in the same dormitory as the two last boys was peeling on both feet in large flakes. (Being a monitor he had been allowed, unofficially and unfortunately, to escape the matron's inspections.) I isolated him at once, and next day found a small slough hidden between the right tonsil and the posterior pillar of the fauces. A swab from this gave a growth of a hæmolytic streptococcus in large numbers. On cross-examination he gave a history of having been at various camps all August, and of having felt ill one day with a slight sore-throat on returning home in the first week of September. He had noticed that his hands peeled slightly about a week after, and his feet began to peel about the time he came back to school—i.e., about 14 days after the throat. This history would do very well for para-scarlet A, and at first sight the apparent incubations of the three cases would support this, but on further inquiry a definite single contact with the first boy, dating three days before his illness, was discovered, and the carrier was found to have been in closer contact with the other two in the dormitory during the second week than during the first week of term. This supported the diagnosis of scarlet fever and the subsequent cases gave definite house

TABLE OF DISTINGUISHING FEATURES.

—	Morbilli.	Rubella.	Scarlet fever.	Para-scarlet A. (Fourth disease.)	Para-scarlet B. (Epidemic roseo of Dukes.)
Incubation.	10 days to prodromata. 13–14 days to rash, body. 10–16 days extreme limit.	No prodromata. 12–16 days to rash. 14–15 average.	1–6 days. 4 average.	(?) 8–12 days. 10 average.	12–16 (? 22) day 14–15 average.
Prodromata.	Fever with remissions. Coryza. Sneezing. Cough at first hard and dry. Malaise 2 or 3 days.	Usually no fever. Occasionally sneezing; slight sore-throat.	Continued fever. Vomiting. Sore-throat. Headache and pain in back and limbs. Sometimes rigor.	Fever unusual. Occasionally slight sore-throat or headache. Often entirely absent.	Usually entire absent.
Temperature.	101–104 or more. Often remits. lasts 4–8 days.	Often none. May be 103. If present always remits. Lasts 1–3 days.	101–103 mild cases. 103–106 severe. Usually continued. Lasts 4–8 days.	Often none. May be 104. Usually normal or 99 in 24 hours.	Usually none 99, and norm in 24 hours. O casionally high
Pulse.	In proportion to fever.	Unaffected.	Much out of proportion to fever.	Often unaffected, if quick, not in proportion to fever.	Usually unaffect
Malaise.	Considerable.	Usually absent.	Considerable.	Usually absent, if present is very short. (*See A at foot.*)	Usually absent
Eyes.	Red, watery, with marked photophobia.	Pink, but without any photophobia as a rule.	Bright.	Usually unaffected.	Unaffected.
Mouth.	Koplik's spots appear 2 days before rash on body in 75 per cent. of cases.	Rash appears on soft palate at the same time as on body.	Gums injected, but no typical rash.	Mucous membrane, as	a rule, unaffecte
Throat.	Tonsils and palate red and swollen.	Tonsils red but not septic.	Tonsils dark red like raw beef. Sloughy or follicular.	Tonsils red, usually not so sloughy as in S.F.	Tonsils usual unaffected.
Nose.	Occasional epistaxis.	Epistaxis rare.	Epistaxis rare. Nose clean.	Epistaxis common. Nose and sinuses blocked with thick pus often from onset.	Epistaxis rar Nose clean.
Tongue.	Thick white fur. Rarely peels.	Normal or slight fur. Never peels.	Covered at start with thick yellowy-white fur (white strawberry) through which the enlarged papillæ show red. In 4 to 5 days peels from edges and tip, backwards (red strawberry).	Moderate fur or normal. Papillæ may be enlarged. If furred peels quickly on 2nd day. Not typical strawberry.	Usually unafecte
Glands.	Cervical, swollen, tender, seldom suppurate. Body, unaffected.	Cervical, chain of posterior glands enlarged, may be hard or soft. Often not tender. Axillary and inguinal often affected.	Tonsillar and anterior cervical, large and tender. There may be a good deal of periadenitis and even suppuration. Often there is a secondary adenitis during convalescence. Body not affected.	Tonsillar enlarged. Often not tender. Never suppurate. Axillary and inguinal sometimes affected.	Usually no affected.
Rash.	Appears 3rd to 4th day in the mouth; 2nd day (Koplik's spots). After the mouth appears on face and behind ears, then generally on body and limbs. Consists of red papular dots which enlarge and coalesce into irregular crescents and patches. May resemble urticaria in pressure areas. Brick-red at first, then dusty. Skin stained after rash has gone.	Appears usually first day of disease. Often is first thing noticed. Usually first on face and chest, spreading thence to body and limbs. Often coalescing to resemble in parts the rash of morbilli. The typical rash consists of discrete rose-red papules. If profuse, skin may be left stained.	Appears usually 1st to 2nd day of disease. Begins on chest and then spreads in regular order over trunk and limbs from above, downwards. Never on face, soles, or palms. Circum-oral pallor is marked. Is a diffuse punctate erythema. Skin is markedly hot to the touch.	Appears 1st to 4th day of disease. May be first thing noticed. Usually begins over lower abdomen and upper and inner thigh area; then inside knees and ankles. May spread thence irregularly over body. Face often puffy but not definitely erythematous. Palms and soles may be involved. Is a diffuse erythema occasionally punctate, especially over pressure areas.	Resembles i general featur distribution a onset, that para-scarlet but is usual much less inten and often lar areas of the bo are unaffected.
General constitutional symptoms.	In proportion to the amount of fever and rash.	Usually slight.	In proportion to the amount of fever and rash.	Markedly slight in proportion to fever and rash.	Usually ver slight.
Desquamation.	Branny.	Branny, if any.	Usually complete and massive. On tongue from 4th to 8th day. On body commences as a fine peach bloom below clavicles about 8th day, followed by fine desquamation spreading thence over trunk and limbs. (*See B.*) Lasts 8–28 days or longer.	Occasionally absent. When present tongue peels completely in 1–2 days, usually on 2nd or 3rd day of disease. On body, varies fromnone, to slight branny, to shreds, but is not "glove" or typically "pin-point." Lasts 1–3 weeks, may be longer.	Tongue neve Body usual absent; if it c curs, resembl that of par scarlet A.
Period of infectivity.	From start of prodromata (at maximum before rash is out on body) for about 14 days, if throat, ear, and kidney are then clear.	Over with rash. Maximum before rash is out.	Probably from start of prodromata (maximum during 1st week) till end of 3rd week if throat, ear, and kidney are then clear.	Probably from start of prodromata (maximum before rash is out on body) for about 10 days if throat and sinuses are then clear.	Over with ras Maximum befo rash appears.

A = Patient feels well and can read books even with considerable fever, in striking contrast to condition in S.F.
B = Later on scales and shreds, especially on limbs; "glove" peeling on hands and feet, and "pin-point" on trunk and limbs distinctive.

TABLE OF COMPLICATIONS AND SEQUELÆ.

—	Morbilli.	Rubella.	Scarlet fever.	Para-scarlet A. (Fourth disease.)	Para-scarlet B. (Epidemic roseola of Dukes.)
Kidneys.	Transient albuminuria rarely during fever. Nephritis very rare.	Transient albuminuria very rare. Nephritis never.	Transient albuminuria during fever common. Nephritis fairly common.	Transient albuminuria during fever rare. Nephritis very rare, if ever.	Transient albuminuria very rare Nephritis never.
Lungs.	Bronchitis practically a symptom of the disease. (*See C.*)	Nil.	Pleurisy, especially after pneumonia, if this occurs.	Nil.	Nil.
Heart.	Rarely affected.	Never.	Endocarditis, simple, not uncommon; infective, uncommon. Myocarditis, not rare.	Endocarditis, as in scarlet fever.	Never.
Middle ear.	Pneumococcal infection common.	Never unless previously affected.	Streptococcal infection common.	Infection uncommon.	Never.

class contacts of two to six days, confirming the diagnosis. ne carrier and one other boy were said to have had pre-ous attacks of scarlet fever in 1909 and 1916 respectively, it both at home. One boy had had rubella.

Summer, 1922.—Para-scarlet A. Seven mild cases, cept for one boy who had had definite severe scarlet fever home in 1912. In the present attack he was not at first ry ill. His aspect was typical of severe para-scarlet A, se blocked with muco-pus, voice thick, tongue not thickly rred, temperature high, but pulse-rate not in proportion to ver. The rash came out on the second day, first on the wer abdomen and groins, then knees and feet, and then l over. With this he did not at first feel very ill, but on e third day he suddenly became delirious and developed gns of meningeal irritation. He was then treated with veral doses of polyvalent antistreptococcic serum, and ereafter steadily improved, being well out of danger in o days. Of the seven cases three had had definite pre-ous scarlet fever, and one definite previous rubella. able II.)

1918.—Nil. L = Lent; S = Summer; W = Winter.

The epidemics of scarlet fever, para-scarlet, and ubella have only occurred together once—viz., in ne summer term of 1916, when there were 148 cases rubella, 45 of para-scarlet, and 11 of scarlet fever. carlet and para-scarlet occur in two groups; from ne Lent term of 1915 to the winter term of 1916 arlet fever occurred three times and para-scarlet ree times, but only once coincidently. From the inter term of 1920 to the winter term of 1922 scarlet ver occurred once and para-scarlet four times, but ot coincidently. Rubella occurred coincidently ith scarlet fever three times in the first group, and with para-scarlet twice, once in each group. Table III. gives these dates graphically.

Rubella occurred in nine other terms unaccompanied by either scarlet or para-scarlet fever, the numbers in each epidemic being 3, 1, 5, 54, 2, 1, 1, 275, and 9. In none of these outbreaks were there any cases of

erythematous rash. Morbilli epidemics occurred four times in association with rubella and once with para-scarlet, and once alone, in the summer term of 1921, in the Preparatory School. In the Lent term of 1917 there was an epidemic of 59 cases of morbilli, together with one of 54 cases of rubella which was associated with 236 cases of pink-eye. This is the only epidemic of pink-eye I have seen in ten years. Other isolated cases have occurred from term to term, but it has never become epidemic, possibly because each case is now immediately isolated until cured. It is highly infectious, and I have often noticed occasional cases occurring during an outbreak of rubella.

In a school run on the lines of Christ's Hospital it is possible to trace out contacts in most epidemics until the third or fourth batch of cases, when the incubation periods become concurrent or overlap, as one can find out the movements and whereabouts of any boy for any hour of the day. My experience is that the dormitory and dayroom are more probable areas of infection than classrooms, with the exception of the art and manual schools, but that the tuck shop is a congregational danger-spot that unfortunately defies too often the efforts of the epidemiological detective. In 1916 I satisfied myself and the art master that infection was conveyed from boy to boy by pencil and paint-brush, and a system of routine disinfection with formalin was instituted and is still carried on. The para-scarlet epidemic of the summer of 1922 showed another unsuspected focus in the art models; it was proved that the two boys concerned here had not used the same tools, but had, in

consecutive periods, sat at the same table and used a common model.

Diagnosis of Para-scarlet A and Para-scarlet B.

The diagnosis from scarlet fever of the para-A variety is a matter of some difficulty and, with a first case, depends mainly on seeing the rash come out. The rash usually begins over the bathing drawers area and spreads from there both up and down very quickly. It spreads up the trunk to the neck and face, though the circum-oral and post-auricular regions often escape. It spreads irregularly down, appearing first at the inner sides of the knees and ankles, and from there over the legs and feet. The arms are usually invaded last. The other outstanding features are the very slight constitutional disturbance, as compared with the profuse rash, and the absence of the typical tongue and throat. The diagnosis of this variety from rubella presents less difficulty. The incubation period is from 8 to 12 days, usually 9 or 10.

The para-B form corresponds to the milder form of scarlatiniform rubella (the epidemic roseola of Dukes). Here the whole picture is very mild and the rash often indefinite and very patchy, large areas often escaping invasion. The incubation period is from 12 to 22 days, usually 14 or 15 days.

In four of the outbreaks of para-scarlet A, where it is possible to trace contacts, there were found to be known contacts between cases giving incubation periods of 9 to 15 days. It is hardly possible that an unknown S.F. carrier would be missed in four different outbreaks, or that if he were missed the epidemics would have stopped with so few cases. This suggests that we have to deal with a disease that in many respects resembles scarlet fever, but which differs from it in definite symptoms and which has an incubation of 9 to 15 days, or possibly longer. Either this disease is not scarlet fever or the incubation period of scarlet fever is longer than six days.

In Osler[8] the rash of rubella is described simply as papular; in Allbutt and Rolleston[9] as papular or pseudo-crescentic, and mention is made of an aberrant scarlatiniform type, but in all the school books dealing with infections that I have seen three types of rash are given: (1) the rose-red papule; (2) the crescentic morbilliform; (3) the erythematous or scarlatiniform. It is also stated that a constant sign is enlargement of the posterior cervical glands. Now I have never found a typical chain of enlarged posterior cervical glands in cases of the so-called erythematous type of rubella where the rash is erythematous from the start. In my experience the enlargement of these glands is most marked in the papular variety, and present, but less markedly so, in the morbilliform type of case. This is what one would expect if it is a defensive enlargement.

I believe that there is only one anatomical type of rash for any one acute infection, and it is my experience that in true rubella the rose-red papule is always present at first, but in moderately severe or serious cases it tends to become confluent in areas, giving the crescentic or morbilliform appearence. It is surely unscientific to expect the toxin of an acute fever to produce more than one type of rash. A mild dose of scarlet fever toxin dose not produce a morbilliform or rubelliform eruption; why, therefore, should the rubella toxin sometimes produce a scarlatiniform rash? Undoubtedly cases occur of a scarlatiniform rash associated with enlargement of all the cervical glands, but not especially the posterior, and these cases appear to have a long incubation of 15 or more days, with a possible maximum of 22 days, thus resembling the incubation period of rubella.

I suggest that these erythemata with longer incubation periods are para-scarlet B. The fact that three types of rash are described, and that so many names have been attached to the disease, is good evidence that there is a considerable diversity of opinion about rubella.

I suggest that there are two para-scarlet fevers and a scarlet fever, and not one scarlet fever, one fourth disease, and a third variety of rubella. The first two types of rubella, as commonly described are, I believe, one—the papular which may become confluent. The third type I believe to be para-scarlet B. Thus we have:—

Scarlet fever	Incubation	1–6 days, commonly
Para-scarlet A (fourth disease)	,,	9–15 ,, 1
Para-scarlet B (scarlatiniform rubella)	,,	14–22 ,, 1

I also believe that the causative organism is a hæmolytic streptococcus, and I think there is an increasing body of evidence in favour of this view.*

Complications and Treatment.

Para-scarlet B is very mild and only requires rest in bed during the period of the rash, an initial purge and a regular mouth-wash. A precautionary examination of the urine after the appearance of the rash is advisable.

Scarlet fever and para-scarlet A may be taken together. Severe cases of para-scarlet A can be much worse than the modern form of scarlet fever. It may assume a fulminating or malignant form with death in a few hours from a massive dose of toxin. On the other hand, it may be very mild from the start. The complications of the para form differ markedly from those commonly associated with scarlet fever. Septicæmia and endocarditis may occur but the commonest complication (almost a symptom) is a purulent infection of any of the accessory sinuses of the face, and very occasionally the middle ear. The two antra or the frontal sinuses are often attacked at the commencement of the illness, and require very frequent and active treatment. I have not seen nephritis or rheumatism either as an early or late complication in para-scarlet. Albuminuria is usually absent even in the acute febrile period. I use Milne's method of inunction with eucalyptus oil combined with painting the fauces with 25 per cent. carbolic in glycerine, and so far I have found this perfectly safe in preventing the spread of infection, so much so that when pressed for room I nurse the cases in a small ward in the general block on the same floor as the general work. If the ordinary work is heavy it is wise to have a special day nurse to carry out the main treatment, but if it is not I let one nurse attend both infectious and non-infectious cases. I have not so far had a case of cross-infection under these conditions. The inunction is done all over twice daily during the first week or while the fever lasts, whichever is the longer, and then once daily for a second week. The throat is swabbed thrice daily at first, with a cotton-wool swab on a stick or glass rod and not with a paint-brush. The paint forms a clean scar over the mucous membrane and can be changed for a carbolic and potash gargle as soon as the throat is clear of exudate, usually in two days. It is important to prevent spread from the mouth and throat, and also from the ear, if there is any otorrhœa. Every case should have a nasal douche given with a soft catheter and funnel at least three times a day so long as there is any discharge or secretion in the posterior nares. Bad cases may require douching every two hours. Before I insisted on this as a routine I saw two cases of para-scarlet in which a membranous cast of the posterior nares formed during the first two days of illness and caused very considerable trouble. I find the best lotions for nasal douching are the eucalyptus colloid made up in half the strength advised on the label, or pot. permanganate 1/10,000. The usual pill and senna should be given in every case the first or second day, and I usually give at the start the first night a powder of aspirin grs. v., phenacetin grs. iiss and pulv. ipecac. co. grs. iis., and repeat if the temperature does not come down.

* This was originally written in 1923 before the general acceptance of the *Streptococcus hæmolyticus*, and before the Dick and Schultz-Charlton tests were available in this country; as will be evident from the dates of my epidemics I have since had no opportunity of using these tests in corroboration or the reverse of my thesis.

I now give as a routine an initial dose of 10 to 20 c.cm. of polyvalent antistreptococcic serum (B. W. and Co.) to all cases of both scarlet and para-scarlet A, and repeat this in 10 c.cm. doses if the temperature has not markedly fallen in 24 hours. I am sure that this shortens the toxic stage, and either checks the supply or helps the elimination of toxin, thus lessening the chance of complications. It also seems to shorten the period of convalescence.

The importance of distinguishing these diseases from one another is twofold :—

(1) As the cases quoted by Filatow, Dukes, Weaver, and myself show, neither scarlet fever, the para forms, nor rubella protect against each other, and a wider recognition of their separate nature will help to prevent the admission of the para forms into hospital with cases of scarlet fever.

(2) Recognition will facilitate the early discharge of the para B and the mild cases of para A from hospital; there are few, if any, medical officers who would regard it as safe or expedient to liberate a case of scarlet fever, however mild, under four weeks; while the majority of cases of para A and all of para B can be discharged to ordinary life with perfect safety in two weeks. This is important on the grounds of finance, public opinion, and school management.

THE CONSERVATIVE MASTOID OPERATION.

BY CHARLES J. HEATH, F.R.C.S. ENG.,
CONSULTING AURAL SURGEON, THE DOWNS HOSPITAL FOR CHILDREN; LATE SURGEON, THROAT HOSPITAL, GOLDEN-SQUARE, LONDON.

IN this paper I propose to show to what an extent a change in physiology may prove an aid to surgery in restoring the hearing of the discharging ear. Few medical men realise that the largest ear hospital in this country, probably, indeed, in the world, is maintained by the Metropolitan Asylums Board and is known as the Downs Hospital for Children. Hundreds of children are sent thither every year for mastoid operations, mostly for the cure of chronic aural suppuration, often on both sides. The resident surgeons of this hospital have therefore unique opportunities for practice and experience. A recent annual report of the Board contains a contribution by Dr. Anthony Wrench (assistant medical officer at the Downs Hospital), entitled Some Guiding Principles in the Post-operative Treatment of Mastoid Disease. A note runs thus :—

"These remarks apply to the radical and Heath's conservative mastoid operations. The Schwartze operation is now never performed at the Downs Hospital, as this method of dealing with mastoid disease has not infrequently been found to be followed by dangerous recurrences. The dressings also are more painful; the scar is unsightly; and, worst fault of all, the site of the antral cavity and the drum-head are left practically inaccessible."

These four reasons are given by Dr. Wrench for the definite decision of the resident staff at the Downs Hospital to discontinue the performance of mastoid operations by Schwartze's method. I propose to deal with them seriatim and then to add some others.

Dangerous Recurrences.

The Schwartze operation, designed for the cure of acute mastoiditis (i.e., pus pent up in the mastoid antrum) in early cases of otitis media, is not infrequently followed by recurrences of the acute condition which are dangerous because this operation does not provide for permanent outward drainage of the antrum. This cavity is the only part of the ear in which septic discharge is likely to be pent up so as to destroy life and is also, in chronic cases (in the absence of adenoids and tonsils) the source of that persistent discharge which, in its passage through the tympanum, perpetuates disease there and thus destroys the hearing. At the Ninth International Otological Congress (in America) I cited the statistics of six different observers, embracing 739 mastoid operations for the cure of discharging ears (360 of them my own at the Throat Hospital), in which, without a single exception, disease was found in the mastoid antrum both in acute and chronic cases. This dangerous mucous cavity, less than a pea in size, surrounded by bone, lined with a variable mucous membrane, drained inwards to the tympanum by a tiny channel (the aditus), and situated barely one-sixteenth of an inch (often indeed less) from the brain and the lateral sinus, is only accessible for treatment, surgically or otherwise, by means of a mastoid operation. Operation has proved to be the best remedy in disease of the mastoid cul-de-sac, just as it has in appendicitis.

I have seen dangerous cases of recurrence after the Schwartze operation, most often in public hospitals, such as the Downs, and at fever hospitals, and always in patients who had undergone operations elsewhere. The conditions in these recurrent cases may be as bad as, or indeed worse than, those existing at the time of the original operation. I was gratified, therefore, to learn from Dr. Wrench's article that the Schwartze operation had been abandoned at the Downs Hospital.

Painful Dressings.

The problem of painful dressings in children is so serious that if it had not been solved it is doubtful if the Downs Hospital could have been maintained. Elsewhere I have known chloroform given as often as twice a week for six months for the dressings after Stacke's (radical) operation. Manifestly this would be impossible for the 150 children at the Downs Hospital. At this hospital the after-treatment designed by me (of which Dr. Wrench's article gives the guiding principles) enables one person to dress over 100 patients in a morning. These dressings are carried out more easily after the conservative operation than after any other, because the mastoid antrum—the only part packed—has purposely been rendered easily visible and accessible through the meatus.

An elderly doctor, on whom I recently operated to save hearing, and who feared the operation mainly because of what he described as "the horribly painful dressings" he had previously seen after Schwartze operations, wrote from the country three weeks later, when he had quite recovered: "The painlessness of the dressings has most deeply impressed me."

Unsightly Scars and Inaccessibility.

After the Schwartze operation the wound is left open and disfigurement results; I have, indeed, known plastic operations to be necessary.

The inaccessibility of the mastoid antrum is responsible for danger, and even loss of life, in recurrences after the Schwartze operation, because it does not secure that severance of the mastoid antrum from the middle ear, which is an essential feature of my operation. I ensure that the antrum—through the complete destruction of its lining mucosa—shall permanently cease to be a mucus-secreting cavity draining inwards through a very narrow channel into the middle ear; that it shall be severed from all connexion with the middle ear; that it shall open widely outwards, and become part and parcel of an enlarged and dry external auditory meatus, widely open to the air, so that discharge cannot possibly be pent up. This constitutes a complete physiological change in the function of this dangerous, mucus-secreting cavity, and necessitates a surgical re-arrangement of the hinder end of the middle ear. This rearrangement has a double purpose; first,

that of ensuring the immediate and future safety of the patient's life, and secondly, of arresting the septic antral discharge and resulting tympanic destruction, in order to save the hearing. The procedure entails the removal of nearly the whole front wall of the antrum, so that it is as widely open and as easily visible and accessible as the meatus itself. It was because the tiny antrum is embedded in bone in a dangerous locality and therefore cannot, like the cæcal appendix, be completely removed, that I devised this method of rendering it permanently safe. I have only seen two recurrences of acute otitis media after operations by my method, one 10, the other 14 years later—each being due to a "cold in the head"—a complication against which we can never permanently provide. In each case both the safety-valves gave way under pressure, so both are obviously required. One is the thin membrane which forms across the aditus after the operation (thus separating the antrum from the middle ear), the other is the scar which heals the perforation of the drum-head. Neither of these patients was away from work during the short period of healing. To one patient I was called too late, and I know of other recent recurrences of mastoid disease after the Schwartze method which also ended fatally in spite of repeated operations within four months of the original treatment.

The less serious recurrences after Schwartze operations, admitted into the Downs Hospital, are usually dealt with as follows: (1) A conservative mastoid operation is performed through an entirely fresh skin incision farther forward and close to the ear (as in a primary conservative operation); and (2) the disfiguring scar, and the suppurating sinus, if present, are excised and the wound sewn up. In this way future danger and disfigurement are both obviated.

Prolonged After-treatment.

Open wounds are left after the Schwartze operation and sometimes these never heal; consequently the disfigurement and the foul and visible discharge are a life-long nuisance. Considering the complete and rapid cure effected by timely conservative mastoid operations, even when both ears have been operated upon at one sitting, there seems no justification for allowing thousands of ears to be destroyed in London every year by prolonged suppuration. In the conservative operation there is no shock, pain, or loss of blood to cause anxiety and, but for the sickness from the anæsthetic, the patient would not be at all ill. Not only is the hearing restored, but if both ears are treated the patient seems subsequently to be proof against injury to the hearing by the concussions of big guns.

Facial paralysis and deafness are also liable to be induced during the Schwartze operation through injury of the nerve or dislocation of the incus, because of the difficulty in locating these structures. The tympanic ring and drum-head are not exposed for the purpose of locating them in the Schwartze operation, whereas in the conservative operation they are. This explains some of the hitherto inexplicable cases of deafness following the Schwartze operation.

Suppuration within the sheath of the temporal muscle is apt to occur both in Stacke's (radical) and in the Schwartze operation, because the sheath is opened and the exposed muscle may become involved in the septic process. In the conservative operation the sheath is not opened.

Schwartze's old and so-called "simple" mastoid operation, like the earliest abdominal operations, is altogether too primitive. It constituted an early phase in the genesis of aural operations. While abdominal operations have been improved out of all knowledge since their initiation, the Schwartze operation has remained what it always was—a mere emergency measure, hurriedly improvised to save life by providing temporary drainage for a dangerously situated acute abscess in bone. This operation does not secure the patient against an equally, or even more, serious recurrence; moreover, it was not devised for the preservation of the hearing. In my experience the Schwartze operation is a far more extensive proceeding than the limits of the disease usually justify.

Aural surgery is proverbially unsuccessful in saving the hearing, and it is important that the reason for this should be widely known, that nearly all mastoid operations are performed much too late—that is to say, after the hearing apparatus has been ruined by disease. This deplorable state of things usually arises from inability to diagnose the tympanic conditions; this is not surprising, since the necessary information is not given in any text-book. The surgeon who cannot diagnose these conditions cannot possibly know when he ought to operate to save the hearing. While he waits hearing is lost beyond recovery. It is in this disastrous condition of lost hearing from neglecting to operate when the hearing is endangered that most of the children are sent to the Downs Hospital for operation, and in consequence of this a large majority of the mastoid operations performed there are by Stacke's "radical" method. This operation may put an end to disease and danger, but it does not save the hearing; it was not devised or intended for that purpose. If these children are sent to hospital in time to save their hearing they all undergo operation by the conservative method. Last year no more than 105 cases were admitted for my operation, whereas 267 Stacke's radical operations were necessary. As this entails removal of the drum-head and ossicles, permanently defective hearing in a large majority of these children was the inevitable result.

I have persistently condemned the prolonged treatment of suppurating ears by syringing and drops, and the treatment by ionisation, now in vogue, is little if any, more effective. Thousands of the children who are being thus treated will never hear properly again; the disease has been allowed to exist too long. With few exceptions the longer the disease lasts the more damage is done to the hearing. Persistent suppuration in any situation is destructive, and it is especially so in the tiny channels of the ear.

Short of a conservative mastoid operation the earliest possible removal of adenoids offers far the best prospect of curing a suppurating ear. Attendance as an out-patient at a hospital or school clinic, for the treatment of a chronically discharging ear, is usually a waste of time and, through the delay in admission for operation, often results in the loss of hearing. Destruction of the ear through chronic suppuration is sometimes very rapid and, as pain may be absent, it may not attract attention.

After my introduction of the conservative operation at the Throat Hospital I performed 360 mastoid operations there with only one death; most of these were cases of acute mastoiditis arising in ears that had long been diseased, for which Stacke's radical operation had been previously designed and used. The average duration of the disease in these 360 patients was six years. The long delay was mainly due to lack of beds; but even six weeks is far too long to delay operation if perfect restoration of the hearing is to be made probable. These statistics indicate that a mastoid operation should not in itself be dangerous, though the conditions which call for it often are.

Summary.

The characteristics of the three mastoid operations can now be briefly summed up and compared.

(1) Schwartze's "simple" operation was devised as an emergency measure for use in early acute disease to save the patient's life. It is unsatisfactory, mainly because it was not designed to ensure the future safety of the patient. It has, moreover, many other very serious drawbacks, as pointed out by Dr. Wrench and described above.

(2) Stacke's radical operation was also not devised for saving the hearing, but for curing chronic disease, or acute mastoiditis arising in chronic cases—i.e., it also is life-saving, for the future as well as the immediate present. Nevertheless, it is unsatisfactory, entailing as it does the removal of the drum-head and

ossicles, and rendering the hearing permanently defective.

(3) My method, the conservative operation, besides being life-saving, immediate and remote, is the only one of the three which is designed to preserve the hearing. These twofold advantages are only rendered possible by the physiological change brought about in the function of the mastoid antrum—the distinctive and outstanding feature of the operation.

If the hearing of the persistently discharging ear is to be made and kept safe the only effective and permanent remedy available is a timely conservative mastoid operation—i.e., one which is performed in time to arrest the disease before it has ruined the ear.

ON PORPHYRIN IN THE MOUTH.

BY A. A. HYMANS VAN DEN BERGH,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF UTRECHT, HOLLAND.

I RECENTLY had the opportunity of observing a case of congenital hæmatoporphyrinuria, and this article describes an investigation to which the study of the patient gave rise. Various substances have been classed as porphyrins, partly because of their spectroscopic and other qualities and partly because of their chemical composition. The table shows some of the porphyrins as they are described in current literature with some of their properties. This list is still incomplete, and it is possible that in the future more porphyrins will be added.

Table showing the Qualities of Porphyrins Detected in the Urine.

—	Position of the two principal bands in HCl-acid solution.		Solubility in æther.	From HCl into chloroform.
Coproporphyrin	594	551	Soluble.	Does not enter.
Uroporphyrin..	598	554	Insoluble.	
Kämmerer's porphyrin	602	557	Soluble.	Enters.

The porphyrin hitherto found in the urine of the few cases of congenital porphyrinuria which have been thoroughly examined is uroporphyrin. The traces of porphyrin which can be found in the urine and fæces of normal persons are coproporphyrin.

In the fæces of healthy people who have eaten food containing blood and those of sufferers from gastric or intestinal hæmorrhage another sort of porphyrin is found; to this the name of Kämmerer's porphyrin may be given. This author prepared in vitro, by adding various microbes to blood, a sort of porphyrin, which had the same properties as the substance appearing in the fæces after partaking of meat or blood (Snapper, Pappendieck).

When trying to trace small quantities of porphyrin I made use of their property of displaying a red fluorescence in a dark room when irradiated with ultra-violet light with exclusion of the visible rays. The same method had already been used by other workers (Keller, Langecker, Derrien).[1] The fluorescence test must, however, be accepted with considerable reserve, for many reasons. The solvent and accompanying substances exert a great influence on the phenomenon, so that mixtures or impure solutions are often not fluorescent or do not give the typical colour. On the other hand, various substances (which are, however, generally related) can cause the same fluorescence. Chlorophyll in alcoholic solution, for instance, can produce a fluorescence very similar to that of porphyrin. This does not alter the fact that the phenomenon of fluorescence, on account of the extraordinary sensitivity and simplicity of the method, is of great value as a means of orientation, enabling us rapidly to trace small quantities of a substance. Solutions which appear to be completely colourless by ordinary light give a strong fluorescence. This physical property must, however, always be controlled by other physical and chemical investigations.

Fluorescence of the Teeth and Tongue.

Garrod's[2] work on porphyrinuria dates from 1892, and he was the pioneer of the clinical investigation of this pigment; he[3] and, later on, other English writers[4] noticed that in some cases of congenital porphyrinuria in children the teeth show a beautiful red fluorescence when irradiated with filtered ultra-violet light. My patient's teeth also showed a red fluorescence, not previously described in adults suffering from this disease. When, however, I examined several middle-aged healthy individuals, and patients of all kinds, the same fluorescence was seen in most of them. Closer examination showed that it was near to the implantation in the gums, and varied in amount in different persons. It was easy to demonstrate that this fluorescence was not caused by the dentine (as in Garrod's patient), but by the tartar deposited on the teeth. In the same way, in my case of congenital porphyrinuria it proved not to be the teeth themselves which showed fluorescence, but the tartar. The phenomenon in this case must, therefore, be quite different from that observed by Garrod. Moreover, the back of the tongue also showed a more or less visible red fluorescence in almost every case. Bommer[5] examined by filtered ultra-violet light various organs after death and also the skin and mucous membranes during life. He also found that the tongue and teeth displayed a red fluorescence and, in the latter, that it was the tartar which must be regarded as the cause of the phenomenon.

Porphyrin the Cause of the Fluorescence.

Bommer, however, made no chemical investigations into the nature of the substance causing the fluorescence. My line of research lay in determining whether or not the cause of the fluorescence of the tartar was porphyrin. Recently I learned that in 1924 Derrien,[6] studying porphyrin by means of filtered ultra-violet light, observed red fluorescent spots in fragments of teeth. These he ascribed to the action of microbes, making Kämmerer's porphyrin out of the blood of the foods. Derrien did not, however, actually examine the substance chemically or spectroscopically.

In order to get a sufficient quantity of substance I used a number of teeth extracted in the Dental Institute of the University. The tartar was scratched off and ground fine in a mortar. This powder showed a red fluorescence, as might be expected. By extracting it with a mixture of glacial acetic acid and ethyl-acetate (1 : 4) a solution was obtained which, after filtering, again showed a beautiful red fluorescence. This solution was shaken up with a small quantity of 5 per cent. hydrochloric acid. As is characteristic of porphyrin, the substance passed into the hydrochloric acid, which it coloured red if the concentration was sufficiently strong. The hydrochloric solution of the substance, separated from the upper acetic acid-ether layer in a separation funnel, gave a beautiful red fluorescence, and the typical spectrum of acid coproporphyrin. When the powder or the hydrochloric solution were extracted with chloroform the substance did not enter the chloroform. It is permissible to conclude that the tartar of the teeth contains a substance which, as far as can at present be traced, is identical with, or at least very closely related to, coproporphyrin. It is not difficult to understand how the porphyrin is deposited in the tartar. If an elderly person whose enamel is no longer perfectly smooth does not brush his teeth for one or more days (even this omission is not absolutely necessary) the teeth, some hours after breakfast, will yield a greater or lesser quantity of white deposit, "the materia alba" of Leeuwenhoek.[7] This deposit is soft, pappy, and easily rubbed off. The coating from the surface of the tongue and the dental deposit both give a beautiful red fluorescence in filtered ultra-violet light. If this material is extracted with a mixture of glacial acetic acid and ethyl acetate, the mixture washed out with water, from which it is separated in a separating funnel, and the acetic-ether-solution extracted with 5 per cent. hydrochloric acid, the resulting solution gives the spectrum of acid coproporphyrin. The porphyrin in

this deposit is retained by the calcium salts of the tartar. Tartar, indeed, consists largely of calcium salts, by which porphyrin is readily adsorbed. The material alba gives the fluorescent phenomenon, and —after extraction—the spectrum of coproporphyrin, after a breakfast consisting only of milk and bread, without any meat, blood-containing food, or green vegetables.

The Origin of Porphyrin in the Mouth.

The intensity of the red fluorescence of the materia alba was not greater on the parts touching the gums than it was further up towards the distal portion of the teeth. From this we may conclude that the porphyrin in the mouth does not necessarily arise from hæmoglobin (neither from the hæmoglobin contained in the food, nor from small hæmorrhages out of the gums). Nor is it formed out of chlorophyll from vegetable foods. (I once found the same red fluorescence in the tartar of a horse's teeth.) Moreover, the spectrum of the tartar and the tongue- and teeth-porphyrin does not correspond with that of the porphyrin formed by bacteria from hæmoglobin or that found in the fæces after swallowing blood. Microscopic inspection of a small quantity of the materia alba, smeared directly upon a slide or rubbed with glycerine and water, showed no traces of food particles. In patients who had only eaten bread, milk, and cereals I found no more starch a few hours later. Addition of lugol solution did not produce a blue colouring. Evidently all the residues of the food had been dissolved and the starch had been saccharified. The whole mass of materia alba appeared to consist of a dense net of threads (leptothrix), between which might be seen granules (spores) as well as bacteria. These slide specimens gave off an intense red fluorescence in filtered ultra-violet light. When, however, they were examined microscopically with ultra-violet filtered light the leptothrix threads did not produce fluorescence. After cultivation of the microbes of the mouth (leptothrix has not yet been cultivated on artificial media) we did not discover which of them gave rise to the porphyrin.

Another possible source of the porphyrin in the mouth is the saliva. We have already remarked that the urine of all normal persons contains coproporphyrin, though in very small quantities; we also found traces in the bile. It is probable, therefore, that under physiological conditions it may also be secreted by other glands, for instance, by the salivary glands—and we succeeded in extracting coproporphyrin from the saliva of normal persons in relatively greater quantities than from the urine. The absolute quantity in the saliva is, nevertheless, so small that it seems unreasonable to suggest that the relatively large quantities of porphyrin in the materia alba and on the tongue, formed in a short time, may be ascribed to the porphyrin content of the saliva.

Whether or not the microbes of the teeth play an important rôle in forming the porphyrin of the materia alba, the components of the food are its most likely source. As milk and bread had produced it we examined these foodstuffs for porphyrin and extracted it from both. Fischer had already shown that milk contained small quantities of porphyrin, and we extracted an even larger quantity out of bread. It further appeared that much larger quantities of porphyrin could be obtained from a mixture of milk and bread kept in the incubator for 24–48 hours at a temperature of 37° C., than from the same quantities of milk and bread kept separately. In ordinary baker's yeast kept in the incubator, as Fischer has discovered, large quantities of porphyrin are formed. After incubating yeast for three days we could even see the fluorescence by ultra-violet rays without previous extraction. The formation of porphyrin in bread might be attributed, therefore, to the living yeast cells which are always found in it, but this explanation does not seem plausible, because the cells in bread are so few. It seems more probable that microbes, developing in a mixture of milk and bread in the incubator, are responsible for the formation of porphyrin. It is noticeable that, whilst the mixture did not show a direct fluorescence after several days of incubation, and yeast only showed a faint fluorescence in ultra-violet light after three days, the materia alba of the teeth, which is formed in a few hours, showed an intensive fluorescence without previous extraction.

We do not yet know what happens to the porphyrin formed in the mouth. It is not unreasonable to suppose that a smaller or larger proportion of it is swallowed, but it is not known whether it is decomposed, absorbed, or excreted with the fæces, nor whether it may be a source of error in detecting traces of blood in the fæces according to Snapper's method, and if so how such error may be avoided.

Finally, it may be mentioned that the coating on the tongue which gives the fluorescent phenomenon can only be partially removed. After the surface of the tongue has been scraped rather vigorously it remains fluorescent in ultra-violet light.

TWO CASES OF CONJOINED TWINS.

I.—A THORACOPAGUS.

By C. VINCENT PATRICK, M.B. Camb., F.R.C.S. Eng.,
RESIDENT ASSISTANT SURGEON, ST. THOMAS'S HOSPITAL.

THE thoracopagous or xiphopagous twin monster is only one of the large variety of twin monsters described and classified by Schwalbe.[1] This type consists of two individuals, usually of the same size and always of the same sex, each trunk being complete with normal limbs and head, but joined down the front of the thorax to its twin, face to face. A living example, aged 18 months, has been described by Baudouin[2]; another case very similar to the present is described by Bennett and Patten[3]; and other cases have been described by Berry,[4] Crouzat,[5] and Condon.[6] A similar lamb monster has been described by Berry and Sinclair.[7] Omphalopagous twins, where the union is on the ventral surface but does not involve the thorax, are to be distinguished.

FIG. 1.

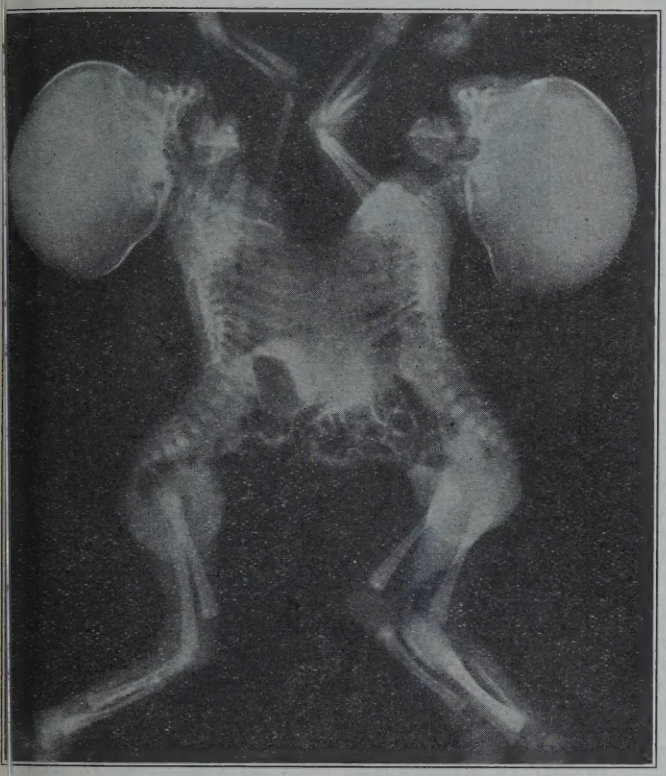
Photograph of the thoracopagous twins during life.

The monster here described was born at nearly full term, and survived four and a half days; its two components behaved as two separate individuals, and died within a few minutes of each other.

Antenatal Examination and Birth.

The mother, aged 27, had previously borne one ild. The delivery was normal, and the child is now ur years old and quite normal and healthy. The

FIG. 2.



Radiogram of the thoracopagus.

t period before the abnormal pregnancy ended on c. 20th, 1926, making the expected date of confine- nt Sept. 27th, 1927. The mother presented herself the antenatal clinic of the General Lying-in spital, York-road, on August 9th, 1927, and I am ebted to Dr. G. W. S. de Jersey, late resident dical officer at York-road, for the following ount of the antenatal findings and of the labour, ich was conducted in the patient's home by a trict midwife.

"August 9th: Liquor amnii above the average. Number limbs felt, — ? twins. One back felt to right, head well pelvis. Only one fœtal heart heard, out in right flank. be seen again on Sept. 6th.

"Sept. 2nd: Called at 4.30 P.M. History of membranes turing at 1 A.M., and slight pains since. Abdomen small, nor evidently having drained away. Head in pelvis. On h right side and left side what appeared to be a back. second head could be found, but an unusual number of bbly parts felt. No fœtal heart heard. Per vaginam: d well in cavity, membranes ruptured, os two-thirds ated. The pains were irregular and short. A soap-and- ter enema was given with good result.

"6.15 P.M.: Per vaginam, os only a rim all round; d seemed small, and delivery expected in a few good ns. After showing at the vulva, the head progressed y slowly, so it was delivered between pains by post-anal ssure. After delivery of the head, no progress was made h the next pain, so slight traction was exerted on the erior shoulder, which came down under the pubic arch. e head was carried forwards, and the posterior shoulder ught under the perineum. No progress was made, and he indefinite obstruction seemed to be occurring above pubes. Locked twins were suspected, and the following nœuvre was made: the shoulders were drawn back in, and the legs fell out under the pubic arch over the erior shoulder. Firm traction backwards was made on shoulders while the patient bore down with a good pain, an assistant used fundal pressure; the buttocks of the t baby were then born under the pubes, followed immediately by the legs and buttocks of the second baby, whose head must have gone back into the hollow of the sacrum, the child having performed version in the cavity of the pelvis. The bodies and legs were now lying forwards, and the head of the first baby backwards and externally near the anus, separated from the head of the second child, which was inside the pelvis, by the perineum. The head of the second child was now born easily, by carrying the whole mass forwards. One baby cried feebly and both breathed well. The cord was ligatured; the placenta was expelled in ten minutes. The placenta, membranes, and cord were normal. There was no damage to the perineum."

Subsequent History.

The monster was admitted to St. Thomas's Hospital on Sept. 3rd, 15 hours after delivery. The external appearance was of two complete female infants, joined together on their anterior surfaces from the angle of Ludwig to the umbilicus (Fig. 1). The area of fusion was 4½ inches long, and approximately 3 inches wide, occupying almost the full width of the anterior surfaces, and showing a sulcus on either side at the line of junction of the two bodies. A single ligatured umbilical cord entered at a common umbilicus at the lower end of the junction. One child was slightly cyanosed, the other a more normal colour. Both were approximately the same size, the total weight was ten pounds. All eight limbs were normal, and each twin cried and moved its limbs independently of the other.

Radiograms (Fig. 2) taken by Dr. Geoffrey Fildes, showed that there was no bony union between the thoracic cavities. Except for the sternal elements, which were displaced upwards and lay in the upper part of the junction, the skeletons were seen to be normal. The hearts and livers were in apposition, and probably fused; each twin was seen to possess its own stomach, but loops of intestine crossed from one to the other, the peritoneal cavity being evidently common.

The pulse- and respiration-rates of one twin differed from the rates of the other; simultaneous counts of the pulses being 120 : 128, 132 : 136, and 132 : 124 on different occasions while in hospital. The rectal temperatures varied between 95° and 97·6°, the cyanosed twin usually having a temperature about one

degree below that of the other. On Sept. 4th both were taking water, and passing urine and meconium. Both cried feebly at times, but seemed

to have a very weak hold on life. On Sept. 5th the cyanosed twin was a better colour. They both took expressed breast milk in three-hourly feeds; they seemed stronger, and their survival appeared possible. The next day however they both became cyanosed and markedly weaker; the one originally cyanosed died at 6.30 A.M. on Sept. 7th, and the other died two minutes later.

Post-mortem Appearances.

A partial post-mortem dissection was made by Prof. F. G. Parsons after the specimen had been hardened in formalin. A complete dissection of the hearts and great vessels was not carried out, as it was intended to keep the specimen as intact as possible for museum purposes.

The thorax contained two pleural cavities and one pericardial cavity. The right lung of one twin and the left lung of the other lay in the same pleural cavity; the lungs were not fused. The two hearts were fused, and lay in a common pericardial cavity. The external appearance of the hearts suggested that they were two normal hearts joined together. A window was cut in the fused cardiac mass, which showed that the wall of the left ventricle of one twin was fused with the wall of the right ventricle of the other, but that there was no communication between them. Beneath the diaphragm, which was continuous across the plane of fusion, there was a single large common peritoneal cavity. The livers were fused, but there were sulci indicating the line of fusion. Each liver had its own gall-bladder and bile-ducts. Each twin had a stomach (Fig. 3), which passed into a short narrow duodenum, into which the common bile-duct of its own liver entered. The two duodenums then joined together in the midline of the plane of fusion, and a common proximal loop of small bowel, with a mesentery, proceeded from the point of junction and lay in loops in the upper part of the common peritoneal cavity. At a point rather above the mid-point of the small bowel, marked by a small blind diverticulum, the intestine divided again; each lower loop of small intestine passed to its own cæcum, colon, and rectum. All the parts of the small and large bowel, with the exception of the duodenum, had mesenteries, and were freely mobile, lying partially in each half of the common peritoneal cavity. There was no fusion of the bladders, and no other abnormalities were observed.

Prof. Parsons points out that the condition of the intestines may be explained developmentally by the fusion of the proximal limbs of the two umbilical loops, the other segments of the intestine remaining separate. This common loop of intestine alone would have rendered impossible the operative separation of the twins, had this been contemplated.

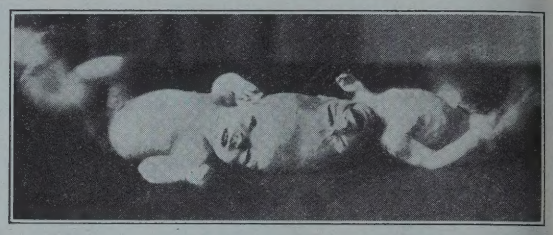
II.—A CRANIOPAGUS.

BY H. C. CAMERON, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN IN CHARGE OF THE DEPARTMENT FOR DISEASES OF CHILDREN, GUY'S HOSPITAL.

THE craniopagous monster was admitted to Guy's Hospital on Dec. 14th, 1927, four days after delivery. The external appearance, reproduced in the photographs, was that of two complete females joined together by the whole extent of the vertex of the skull. The infant referred to throughout as No. 1 was somewhat larger than that referred to as No. 2, had a better colour, and was generally stronger and more active. No. 2 had a left-sided facial paralysis. Both took food well, but No. 2 steadily deteriorated during the six days passed in hospital, growing daily more feeble and suffering for the last two days from diarrhœa. The condition of No. 1 remained good throughout.

FIG. 1.



Photograph of the craniopagous twins during life

We were informed that No. 1 had been born first a breech presentation, the breech of No. 2 being the last part to be delivered.

The pulse-rate in No. 1 was on the average five beats per minute faster than in No. 2. No difference in the temperature and rate of respiration could be noted. Blood counts showed little difference from each other and no abnormality. The infants acted quite independently. At times one would cry, flushing and moving restlessly with bulging fontanelle, while the other slept quietly with a fontanelle quite unchanged. Urine and fæces were passed independently, and vomiting took place at different times in each. The stimulus applied to one produced movement and reaction without disturbing the other. Indigo carmine, 3 c.cm., was injected into the buttock of No. 1 and the dye was found freely in the urine in one and a half hours. In much less amount it appeared in the urine of No. 2 after five and a half hours. The long axis of the infants was not on the same plane, with the result that it was by no means easy to arrange that each lay comfortably. If one lay flat on the surface of the mattress, it was necessary to incline the support slightly for the other in order to attain a position which was not resented.

Since the infants continued to live and No. 2 appeared even to thrive I very reluctantly advised an

FIG. 2.

Lateral view of the fused vertexes.

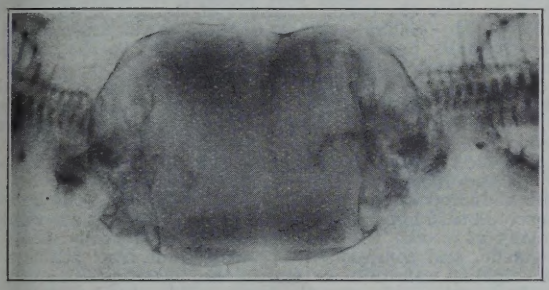
attempt at separation. It was evident from the behaviour of the infants and from the test with indigo carmine that the circulation was continuous only to a slight extent. There was, no doubt, some superficial cutaneous anastomosis, and it was to be expected that the superior longitudinal sinuses were in communication.

Some years ago I had the experience of watching an infant who, on the tenth day of life, suffered from embolic occlusion of the femoral artery of the right leg. A complete line of demarcation formed within a few days, and the infant shed the gangrenous limb with extreme rapidity. On the seventh day after the accident Mr. L. Bromley completed the removal of the limb which had almost completely separated itself. The constitutional disturbance was so slight that the infant actually gained several ounces in weight

allowing for the weight of the amputated limb, during the week in which the separation took place.

With this experience in mind, I thought that it was just possible that the removal of the smaller infant, whose life was already in great danger, might not necessarily entail the death of the larger, provided always that the dura mater in each child was complete, and the subdural spaces separate. During removal of No. 2 it was clear that No. 1 would require no anæsthetic and would lose only minimal amounts of blood if the line of separation was made well to the farther side of the actual line of junction. I thought it possible that if No. 1 survived that any still adhering portions of No. 2 might be shed by the formation of a line of demarcation, and that later some plastic operation might be performed to minimise the resulting deformity. On Dec. 22nd Mr. Bromley was good enough to consent to make the attempt. As a preliminary, blood was withdrawn from No. 2 by Mr. F. N. Reynolds, who kindly attended for the purpose, and stood ready if need had been to transfuse the

FIG. 3.



Radiogram of craniopagus.

infant No. 1. Mr. Bromley then rapidly attempted the removal of infant No. 2, which was anæsthetised by Dr. Eric Scott. During the whole of the early stages of the operation the infant No. 1 rested peacefully, had a good colour, and showed no sign of pain or disturbance, from the active removal of No. 2 which was proceeding. At the point, however, when the subdural space of infant No. 2 was opened the pulse of No. 1 suddenly failed and death was instantaneous. The reason at the same time became apparent. There was a common subarachnoid space, with great deficiency in the development of the dura, and the cerebro-spinal fluid was in free communication, so that the fall in pressure was instantly communicated to that of No. 1.

On post-mortem inspection it was clear that the folds of dura mater were completely developed on the left side of No. 1 and the right side of No. 2, and that the falx cerebri in each case was well-formed. On the right side of No. 1 and the left side of No. 2 the dura mater was defective, so that the corresponding hemispheres of the two infants were only separated by pia mater. The superior longitudinal sinuses communicated about one inch in front of each circular herophili by a wide sinus. The weight of infant No. 1 after death was 4 lb. 9½ oz., of infant No. 2 2 lb. 12½ oz. The length of infant No. 1 was 18¾ in., of No. 2 17 in. The weight of the combined infants at birth had been 8 lb. 4 oz.

In studying these two cases of conjoined twin monsters the most striking feature is the community of the pleural, pericardial, and peritoneal cavities in the thoracopagus and of the intradural space in the craniopagus, a fusion which renders attempts at separation useless.

RECORDER'S SALARY FOR A HOSPITAL.—Mr. R. H. Vernon Wragge, Recorder of Pontefract, announces that he intends to bequeath the whole of the salary he has received, or will in the future receive, as Recorder to the Pontefract Infirmary. Mr. Wragge has held the position for 23 years and the total amounts at present to about £1000.

LEUCOCYTIC CHANGES RESULTING FROM THE TREATMENT OF PERNICIOUS ANÆMIA WITH LIVER.

BY L. E. H. WHITBY, M.D. CAMB., M.R.C.P. LOND.,
ASSISTANT PATHOLOGIST, MIDDLESEX HOSPITAL.

IN observing and recording dramatic alterations in the blood of a case of pernicious anæmia under liver treatment it is not surprising that attention should concentrate on the red cells and hæmoglobin, for these two factors are the essential features of the disease. Nevertheless, liver treatment appears to have a definite effect also on the leucopenia of pernicious anæmia and to produce transient but obvious changes in the differential count.

Four cases only are recorded here, but what might have been an individual reaction in the first and most striking case seems to be quite usual in view of the similar though less marked results in three further consecutive cases. The common leucocytic blood picture in pernicious anæmia is a leucopenia with a relative lymphocytosis, a picture common to many chronic intoxications. Adequate liver diet appears to stimulate the production of leucocytes so that the leucopenia is abolished. In two of the cases here described the relative lymphocytosis disappeared and the differential count became normal except for a transient but definite eosinophilia. Eosinophilia was found in all four cases; it was so marked in the first case, rising to 26 per cent. after 11 weeks' treatment, that the same feature was carefully searched for in the other three, and though never reaching so high a figure was always present to the extent of a few points above the somewhat generous maximum normal figure of 5 per cent. The eosinophilia seems

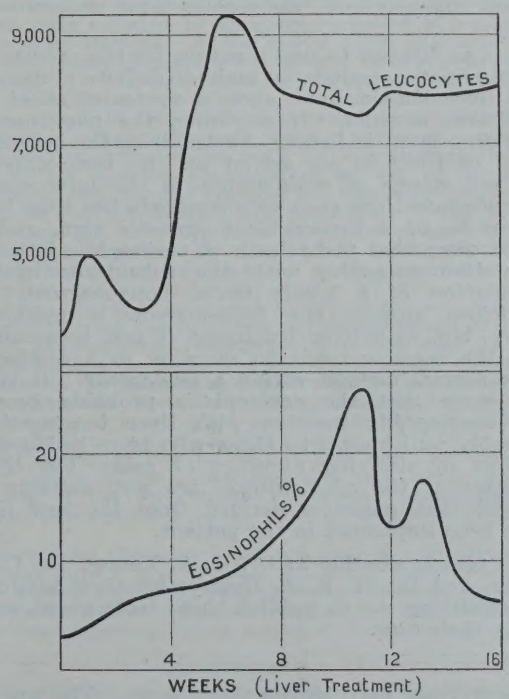


Chart showing alterations in leucocyte count in Case 1.

to be a part of the patient's reaction to the treatment, and the transient nature of the phenomenon points to a parallel between the reticulocyte reaction and the increase in eosinophils. The appearance of reticulocytes in the blood is the earliest favourable indication as to the prospect of a good result; the eosinophilia appears after the reticulocytes have gone and when

the patient is well on the way to having a normal blood count. It is conceivable, therefore, that eosinophilia will be found to be another favourable prognostic sign, and in support of this suggestion it may be stated that all the present four cases have done well with liver treatment.

The following extracts from the blood count records of the four cases show the essential features commented on above, expressed in relation to the time interval after beginning liver treatment. The red cell count in all the cases was greater than 4 million by the time the eosinophilia exceeded 5 per cent.

CASE 1 (see chart).—Treated with 4 oz. raw liver per diem given as a cocktail in orange juice. Eosinophilia 7 per cent. after five weeks' treatment, rose to 26 per cent. in 11 weeks, and subsided slowly to 5 per cent. in 15 weeks. Leucocytes rose to normal figure. Relative lymphocytosis not greatly affected.

Blood Count after Commencing Liver Treatment.

	CASE 2.			CASE 3.		CASE 4.	
Time in weeks:—	0	5	8	0	10	0	7
Total leucocytes..	4,800	11,200	13,200	6,000	6,000	3,200	5,100
Polymorpho-nuclears (%).	64	69	64	51	68	47·5	44
Lymphocytes (%)	32	24·5	26	41·5	23	49	40
Eosinophils (%)..	1·5	0·5	8	0·5	6	1	7

CASE 2.—Treated with 6 oz. cooked liver per diem. Mild leucocytosis with disappearance of relative lymphocytosis within five weeks. Eosinophilia 8 per cent. in eight weeks.

CASE 3.—Treated with 4 oz. raw liver per diem given as sandwiches. No effect on total leucocytes within ten weeks but relative lymphocytosis disappeared. Eosinophilia 6 per cent. in ten weeks.

CASE 4.—Treated with 3 oz. cooked liver and 3 oz. raw liver per diem. Total leucocytes increased. No effect on relative lymphocytosis. Eosinophilia 7 per cent. in seven weeks.

It is as difficult to find a reason for the occurrence of eosinophilia as it is to make a definite statement why liver should have such a profound effect on pernicious anæmia. If anything, the phenomenon is another point in favour of attributing the beneficial effect of liver to its action on the bone-marrow. The occurrence of eosinophilia in the later stages of acute infections such as pneumonia has long been known to be a favourable prognostic sign, and it would seem that the release of eosinophils into the circulation coincides with the subsidence in the stimulation of a highly taxed bone-marrow. In pernicious anæmia the bone-marrow is markedly active, but with liver treatment it can be assumed that the marrow tends to function in a distinctly more normal fashion within a few weeks. It is at this stage that the eosinophilia probably occurs. The eosinophilic reaction with liver treatment is probably well known to those who have had opportunities of studying numbers of cases, but those unaware of the phenomenon are not unlikely to suspect that parasites derived from the raw liver have been implanted in the patient.

My thanks are due to Dr. R. A. Young, Dr. C. E. Lakin, and Dr. H. E. A. Boldero for their kindness in permitting me to publish these facts about cases under their care.

HOSPITALS AND MOTOR ACCIDENTS.—The annual report of Manchester Royal Infirmary states that the average daily number of casualty cases in 1920 was 50. It is now 80, chiefly road accidents. This means, the report points out, that a casualty case is brought in every 18 minutes throughout the day and night.—The chairman of the Hounslow Hospital of 47 beds states that the heavy traffic on the Great West Road has compelled the setting up of a casualty service quite outside its normal function as a local institution. Last year 80 motor accident cases occupied beds for 1680 days, and only £74 10*s.* was received on account of them.

Clinical and Laboratory Notes.

A CASE OF TETANUS.

BY S. BERMAN, M.B. LOND., M.R.C.S. ENG.,
MEDICAL OFFICER, FULHAM HOSPITAL.

THE following case of tetanus seems to be worthy o record, not only because of the comparative rarit of the disease in civilian practice, but also on accoun of the unusual route of infection, the isolation of th bacillus, usually so difficult to cultivate, and th course and result of treatment by antitetanic serun only.

The patient, a boy of 10, was admitted to the Fulhan Hospital on Sept. 10th, 1927, with the following history Twelve days previously, while playing with other children i a public park, one of them poured some lemonade into hi left ear—he strenuously denies that anything except thi lemonade was put in—and the same evening he complaine of pain in the ear; the next day this became more sever and he "felt a lump in the ear"; this was soon followe by a discharge of pus from the left meatus, which continued Six days after the commencement of the ear trouble—i.e. on Sept. 6th—a slight stiffness of the jaw was first noticed this gradually became worse and extended to the cervica and dorsal muscles.

Condition on Admission.—He lay stiff and rigid on the bed his teeth clenched, palpebral apertures narrowed, the angle of the mouth drawn down, giving the typical "risu sardonicus." His head was markedly retracted and th back arched; his upper limbs held stiff and slightly abducte at the shoulders, the elbows semiflexed; the lower limb were abducted at the hips and slightly flexed at the knees One could turn him bodily from side to side just as one woul a plank of wood. He was clear and alert mentally, had n headache, and complained of nothing but his "stiffness. This rigidity was most marked in the masseters—one coul barely insert a thin spatula between his clenched teeth— and in the muscles of the neck and back, where the rigidit could not be overcome at all. In the limbs the stiffness wa most marked in the proximal joints and was not absolute There was a frank discharge of rather foul-smelling pus fro the left meatus which, on examination, showed a norma tympanic membrane but granulations and debris on th posterior meatal wall. All the tendon reflexes were bris and the plantar reflex was flexor. The pupils were equa and reacted well to light and accommodation. The cardia and respiratory systems were normal. There were definit taches cérébrales. Temp. 98° F., pulse-rate 100, and respira tions 24. A careful search revealed no abrasion or woun on the body.

The case was obviously one of severe tetanus, and was decided to institute intensive treatment with antitetan serum by the intrathecal and subcutaneous routes. Th was commenced on Sept. 12th. Under general anæsthes 25 c.cm. of cerebro-spinal fluid, which was quite norma both macroscopically and on detailed examination, wer withdrawn by lumbar puncture and 20,000 units antitetan serum were injected intrathecally; at the same tim 10,000 units were given subcutaneously. The temperatur which had hitherto been normal, rose to 102·2° abou 12 hours after the injection, but dropped to normal agai within four hours. A similar but less marked pyrexia transient duration occurred after each further intrathec injection; otherwise the temperature was normal throug out the illness. The rigidity remained as before, but th patient was comparatively comfortable, swallowed fluid easily, and slept well. On Sept. 13th it was noticed th just before waking from a sleep there were some clon twitchings of the limbs, which were also more rigid ther this lasted for a few minutes only. A second lumbar punctu was performed that day, and the pathologist's report on th cerebro-spinal fluid was as follows: "Turbid fluid wit flocculent deposit. Excess of polymorph cells, 250 per c.cr Albumin: 0·36 per cent. Aufrecht. Globulin presen Dextrose completely absent. pH, 9·5. A film preparatio revealed the presence of Gram-negative intra- and extr cellular diplococci; the fluid was sterile on repeate cultivation." This demonstrates the "meningitic" reactio following intrathecal serum injection; one cannot accoun for the presence of the cocci in the film; they were seen the third specimen examined, but then disappeared com pletely; repeated specimens were constantly sterile energetic cultivation. The patient was given a furth 20,000 units of serum intrathecally and 8000 units subc taneously, and this was again repeated on the following da By Sept. 15th he had received a total of 94,000 units of seru and a slight but definite improvement was noted, especial

n the rigidity of the limbs and back; on this day he was given 8000 units subcutaneously only. He developed a well-marked facial herpes at this time. The following day there were further clonic spasms of the limbs, if anything slightly more severe than previously, and he was given a fourth intrathecal injection of 20,000 units and 8000 subcutaneously. There was a marked improvement from then on, and the patient only received a further 8000 units subcutaneously, making a total of 130,000 units in all.

The bacteriologist's report on a specimen of the pus from the meatal discharge revealed the presence of tetanus bacilli after several days' incubation; they were associated with other sporing anaerobes. The meatitis rapidly cleared up under local treatment. The report on a final examination of the cerebro-spinal fluid on Oct. 5th was as follows: "No absolute increase in cells, but relatively lymphocytes appear in excess. Albumin 0·17 per cent. Globulin present. Dextrose, a trace. Chlorides, 0·7 per cent. Sterile on film and culture. The excess in protein probably a residual effect of earlier reaction."

Apart from a slight stiffness in the legs when first up, the patient made an uneventful recovery and was discharged completely cured.

I have to thank Dr. C. Thackray Parsons, the medical superintendent, for his invaluable aid and for permission to publish this case.

A CASE OF BORAX POISONING.

By John Birch, M.R.C.S. Eng.,
LUTON.

THE following is an account of the fatal case of borax poisoning in a newborn child, to which reference was made in THE LANCET of Feb. 4th, p. 255:—

Clinical History.

I attended the mother for her confinement on Jan. 1st. The child was born an hour before my arrival and appeared normal except than an icterus developed—commonly ascribed to late ligation of the cord—which faded as the days passed. My visits ceased on Jan. 12th, but I was summoned on Sunday evening, Jan. 15th, by a message from the nurse stating that the child was dying.

On arrival I found the child had wasted extremely in the three days which had passed since my previous visit, though regularly fed. He was unconscious and the eyelids were closed. The thighs were flexed close to the abdomen; the legs flexed on the thighs. The arms were pressed to the trunk and the forearms fully flexed on the arms so that each closed hand was pressed to the side of the head just below and touching the ears. The heart beats were normal and the rectal temperature subnormal. The respiration was occasionally jerky—a fact noted by the mother also. The finger-nails and terminal phalanges of the left hand were coloured a bright red or pink, as if painted. The forefinger was red and swollen as far as the wrist. The right hand was normal but the mother stated that the previous day that too was red but the redness had disappeared during the night. The whole of the scrotum, a ring round the anus, and both lips had a similar red appearance, a spot as visible at the external angle of right eye. I found that at least 2 oz. of borax and honey had been given "to prevent thrush"—there was not any thrush.

The colon was immediately washed out with warm water; the washings contained a substance having the appearance of cooked spinach, and the last of them brought away about 3 or 4 inches of what appeared like a mucous cast of the bowel stained green. On Tuesday and Wednesday the child appeared to be reviving and took milk but died suddenly on Wednesday night.

Post-mortem Findings.—The brain appeared normal; pale; ventricles empty; heart empty; bladder empty; intestines almost empty; pylorus normal; duodenum extremely thin walls; liver normal; kidneys very dark, swollen; punctate hæmorrhages under capsule which stripped easily. Lungs normal and expanded. The arterial blood had a pink appearance similar to that seen in carbon monoxide poisoning; post-mortem staining, pink. The stomach contained about 1 oz. of a yellow opaque material having the appearance and consistence of moderately thin honey.

The public seems in general to be unaware that borax is poisonous. For some time I have been in the habit of advising my patients against its use, and in my opinion the two preparations, glycerinum boracis and mel boracis, should find no place in the British Pharmacopœia in their present form.

A NOTE ON NIGHT TERRORS.

By J. W. Shackle, M.A. Camb., M.R.C.S. Eng.,
MEDICAL ASSISTANT, GUY'S HOSPITAL.

NIGHT terrors are often confused with dreams and nightmares, for their outward manifestations are similar. The confusion may arise because writers on this subject have to rely on evidence furnished by a child—as yet unable to express itself and anxious to forget (actively if not passively) an agonising experience—or by a pair of harassed parents. It may therefore be worth while to give a subjective account of night terrors and nightmares, vividly remembered from childhood, which suggests that there is a very sharp dividing line between the two conditions. Briefly stated, the chief distinctions between them were that a nightmare might occur on any night, but especially after excitement or digestive disturbance, and might be repeated several times in the same night, giving no warning of its approach; definite visual images were seen. The night terrors, on the other hand, presented no visual images, occurred only once in the same night, and always gave warning of their approach. Their features were more or less constant, and those from which I suffered had the following character.

On going to bed after a perfectly normal day I usually slept soundly, but occasionally, without any apparent exciting cause, I would be conscious of a feeling of malaise. A small night-light was left burning, and, by the dim light of this, objects normally familiar took on a peculiar aspect. This is best described by saying that they looked larger than usual and possessed an uncanny hardness and what the photographer would call "contrastiness" of appearance; Meryon's famous etching of the Morgue has exactly the grimness and intensity of black and white contrast that was characteristic of the aura of the night terror. In keeping with this the pattern of the wallpaper stood up with peculiar unnatural hardness. There frequently appeared, just before the onset of the terror itself, a phenomenon which I have since come to recognise as a type of fortification figure; it was often replaced by an image consisting of black and white cross-hatching. At the end of about half an hour's continuous aura the night terror followed without perceptible interval. All consciousness of surrounding objects was lost and an image appeared which was peculiar to the night terror. Vague ill-defined masses were seen, some enormously large and others excessively small, conveying a general impression of prodigious contrast. The sensation experienced can be but inadequately described as fear of the most paralysing and dreadful kind, no fear experienced in nightmares or real life bearing any relation to it whatsoever. How long this lasted there is no means of gauging; it seemed an eternity. At the end I awoke exhausted. Objects in the room now had their normal appearance, but my nerve was always greatly shaken by the occurrence, and I had always to be reassured. My mother soon came to understand what had happened and always turned over the pillow, and this action, together with the cool fresh surface, always soothed me to sleep at once. The attack was never repeated in the same night, and attacks mercifully occurred at rare intervals. The aura preceding each attack was so well marked that I never failed to recognise it, and, realising what was about to happen, used to strive to keep "awake," if the expression can be used in this case, and thereby stave off an attack. This succeeded only once, on the occasion of the last attack experienced, when, after a normal aura, nothing further followed, to my unspeakable relief.

Apart from the aura I did not have a true attack of migraine until I was 13 years old, when there were two, after which I remained free until the age of nearly 30, when fortification figures were seen unassociated with headache, on several occasions during a spell of hard reading.

Ætiology.

The number of causes suggested by many writers indicates that the condition is not clearly understood. Among those mentioned are rheumatism, anæmia, tubercle, adenoids, and "gouty gastritis," whilst some authorities suggest that there is usually a family history of neurosis, epilepsy, or migraine. None of these factors, except the last, apply in the case described, but it seems possible that the attacks are the expression of a form of migraine, the aura and visual images affording evidence in favour of this

view. Somnambulism is regarded by some writers as an associated disorder ; but the two solitary occasions on which I walked in my sleep did not coincide with night terrors and were not associated with night terror phenomena.

Most writers seem to agree that there is no recollection of a true night terror, but it is highly probable that the cases they cite are pure nightmare, as indeed their descriptions suggest. An aura occurring during consciousness is not likely to be forgotten, even if the night terror itself were not remembered. The nightmare due to stifling by the pillow is definitely different and has also been experienced by the writer ; adenoids seem more likely to cause this than a night terror.

H. C. Cameron regards night terrors as due to a form of acidosis, and claims to be able to cure them by the administration of glucose. Cyclical vomiting and the allied disorder migraine may be associated with slight acidosis, and the success of this treatment would in that case support the view that migraine may be an ætiological, or at least a related, factor. As, however, most children with night terrors have long periods of freedom, treatment of any kind is likely, apart from suggestion, to meet with apparent success, and the fact that only one attack occurs in a night seems definitely against the suggestion that acidosis bears any relation to the disorder. In fact each attack seems to be a little "brainstorm" on its own, and once it is over nothing further remains to mark its passage. What trigger fires it off in the first place we have yet to discover.

Conclusions.

1. Night terrors are well-defined phenomena bearing no relationship or resemblance to nightmares. 2. They may be preceded by a definite aura resembling migraine. 3. The visual images of a night terror never take the form of objects seen in real life. 4. There is definite recollection on waking. 5. The sensation that predominates is one of overwhelming fear that is out of all proportion to the apparent significance of the stimulus. 6. The terror never recurs in the same night. 7. These observations are compatible with the suggestion made in Garrod, Batten, and Thursfield's "Diseases of Children" that migraine may be a related factor.

I am indebted to Dr. R. D. Gillespie for valuable suggestions.

Medical Societies.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Feb. 1st, Dr. W. T. ROWE being in the chair, when Dr. JOHN FREEMAN read the following paper upon the

PATHOLOGICAL MECHANISM OF THE ASTHMA SYNDROME.

"Asthma syndrome" signifies here that family of diseases or disabilities of which asthma is such a conspicuous example. It will be convenient to have this list before us at the outset.

Bronchi and bronchioles	Asthma itself.
Air passages ..	Paroxysmal or vasomotor rhinitis ; hay-fever is perhaps the best example, and, indeed, serves as a type for the whole syndrome for purposes of experiment.
Gut..	Food idiosyncrasies– e.g., egg or fish sensitiveness.
Skin	Urticaria, eczema, ichthyosis ; also mixtures of, and intermediate stages between, any of these three.
Subcutaneous	Angioneurotic œdema.
Kidneys.. ..	Functional albuminuria.
Joints	Paroxysmal hydrarthrosis.
Brain	Migraine and epilepsy.

There are almost certainly other symptoms, and I would like to put in tentatively :—

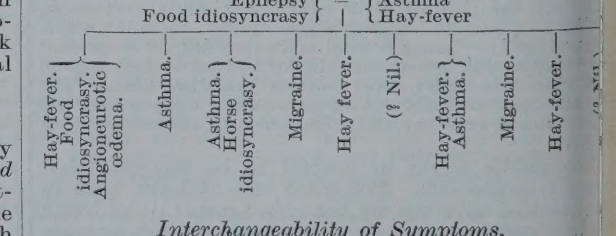
Skin	Dermographia ; this is clearly connected with our group by heredity.
Gut..	Paroxysmal colitis.
Lymphatic ..	White leg.

Now in looking at such a list one notices that some, at any rate, of these items are mere symptoms (urticaria and migraine, for example). I suggest that *all* these conditions are, or may be, symptoms of a particular abnormality, disorder, or kink in the immunological mechanism. It is true, of course, that the whole question can be surveyed from other standpoints : the psychologists, for example, make enormous claims ; the metabolists have their own point of view ; and the laryngologist thinks laryngologically about rhinitis, for example. If you ask an immunologist to talk he will state the pathological mechanism in terms of immunology.

Immunological Specificity.

This immunological disorder is a kind of hereditary and most capricious "anaphylaxy." The *specified* people who have it have in consequence blood circulating in their veins which, when mixed with some *specified* but quite innocuous substance, will make with it a poison mixture. This poison mixture promotes œdema or urticaria (by a very complicated mechanism), it may cause non-striated muscle to contract, and it promotes mucous discharge. It is these various reactions which build up the various items in the syndrome. Note that specified people react to specified foreign substances. This extreme specificity is a well-marked feature of immunological phenomena. An example will make this plain. A hay-fever patient is a man apart ; a normal man can put into his own vein 100 times the dose of pollen which lays any hay-fever patient flat on the floor ; it will circulate round, producing no symptom whatever, the effect on him will be no greater than, say, the effect on a crocodile of 1000 times the human lethal dose of tetanus toxin. If at midsummer the normal man goes into sunny meadows during the week-end he will return on Monday morning feeling all the better for the outing, but he will have so much grass pollen circulating in his veins that a drop of his serum will set up a marked urticarial reaction when injected into the skin of the hay-fever patient. Or conversely, the injection of hay-fever serum into the skin of our week-ender will provoke the Prausnitz reaction which I shall mention later. Then, again, the grass pollen is specific ; no other substance will bring on an attack of hay-fever in a hay-fever subject, though, as we shall see, he may have several other sensitisations going on at the same time. Pollen is the one substance which will make, with his serum, a poison mixture.

The underlying immunological disease is hereditary ; indeed, it is doubtful if it can be acquired in any other way ; but it is handed down not as hay-fever, asthma, epilepsy, &c., but as a tendency to an immunological kink which may give rise to any of these symptoms. It is true that sometimes one particular disability– e.g., hay-fever—tends to run in a family, but far more frequently the type of symptom varies from individual to individual ; for example, an asthmatic father may have a child with bad migraine, who, in turn, may have children showing angioneurotic œdema, hay-fever, and so forth. Evidence of this can be multiplied to any extent, but one example will serve.



Interchangeability of Symptoms.

If our thesis is true, and these various manifestations are symptoms of some underlying lifelo

ondition, we shall expect to find that they are orrelated; they will alternate, or synchronise, or nerge into one another, &c. This is exactly what appens. The life-history of an asthmatic patient requently starts with food difficulties—e.g., diffi-ulties of weaning, &c.; and special food idio-yncrasies may be accentuated to almost any extent nd may persist through life. Often, however, these ade out, and we hear in early school-days of eczema; hen, perhaps, hay-fever through early adult life; nd bronchial asthma in old age. The symptoms may lternate; mothers will say, "I am really glad to ee the eczema coming out, doctor, for I know the oor little thing will not have the terrible head-ches." Or, on asking a patient how the asthma as been this last week, "Oh! I have been having he bumps (i.e., angioneurotic œdema) this week"; nd then perhaps a week later the report will be nettlerash this time, doctor, but now and then have had attacks of asthma too." That these ymptoms synchronise is an everyday experience; rticaria with food idiosyncrasies is almost the rule; nd migraine is extraordinarily common with any of iem. To look at this matter of synchronisation another way, if we are anxious to find the supposed arities, such as ichthyosis, paroxysmal hydrarthrosis, r functional albuminuria, it is only necessary to ook through a biggish asthma clinic (such as the one t St. Mary's Hospital) to find that they are not at ll uncommon, if one knows where to look for them.

Ringing these Changes on Hay-fever.

The artificially produced symptoms give, perhaps, he most striking proof that they all proceed from he immunological abnormality. As usual, hay-ever is our best case for experiment; normally, he pollen lands on the eyes, nose, and throat of the usceptible person, giving rise to the well-known linical entity, hay-fever. This can be reproduced n say, December, by causing our patient to snuff up ollen. If a small quantity of pollen extract is njected into his skin, you will produce an urticaria rrounded by an erythema—the well-known dermal eaction in fact. If the pollen is given in his food or rink he will get abdominal symptoms, sickness, and iarrhœa (it should be noted, however, that it takes large quantity of pollen to produce this reaction). f the pollen extract is injected into the vein (or ubcutaneously for that matter), one is, so to speak, roadcasting the irritant over the whole body of the usceptible person, and varied symptoms follow; here is usually some urticaria in about seven minutes, ith a tingling of the skin; equally common is n attack of angioneurotic œdema, generally in the ace, but it may be in any selected part of the body; hen perhaps migraine; if the patient is at all given o asthma from any cause he will almost certainly et an attack; vomiting and diarrhœa are fairly ommon; and with any really well-marked general eaction one gets albuminuria. (As albuminuria is symptom which has not previously been described, is as well to give details. The albumin is well arked in the urine an hour after the dose, reaches s height at about two hours after, and after this falls apidly, showing the merest trace, or nothing at all, n four hours. I have found it as heavy as 0·2 per cent. n the two-hours specimen: the proportion of albumin o globulin being about 2 to 1—i.e., the proportion ne would expect in a true functional albuminuria.) nce, by an injudiciously large dose of pollen vaccine n my hay-fever clinic, I have produced a fit of pilepsy. Symptoms of rhinorrhœa—i.e., the natural ymptoms of hay-fever—though they occur, are not t all prominent, perhaps because both the patient nd the doctor are distracted by more novel or larming symptoms.

The Prausnitz Reaction.

One may make the disease artificially in the normal an. If the serum of a hay-fever patient is injected nto a normal man's skin this injected area becomes nd remains sensitised to pollen; and a reaction may be produced either by injecting pollen into this area or by injecting pollen into the blood stream and allowing it to be carried to the area. This disease by proxy, the Prausnitz reaction, has about it the elements of a crucial laboratory experiment, and it is worth while to give an example in illustration. If sera are taken from a hay-fever subject, from a horse asthmatic, and from an egg-sensitive subject respectively, and are injected into three several areas of the skin of a normal man we shall have three sensitised patches. Let us allow them all to lie fallow for a day or so and then inject into the vein of the other arm a good dose of pollen. Nothing will happen to the body generally, but where the hay-fever serum has been injected, and there only, will appear a reaction; this will approximate to urticaria or angioneurotic œdema, according as the serum has remained superficial or gone deep. If a day or so later we inject horse substance into the three areas, we should get a reaction only on the area injected with horse serum. Finally, our experimental man, who has been kept off all eggs in his dietary up to this moment, if he is made to drink an egg-flip will find a tingling in the "egg" area after 20 minutes, which will reach its height in urticaria in perhaps an hour and a half, thereafter to fade slowly.

The Localising Factors.

If all these varied symptoms may follow from the immunological kink, why do we sometimes get the lungs affected, sometimes the skin, or the gut, or the brain? Why, again, do the attacks suddenly come on with a run or stop as suddenly; in fact, why do they come on more at one time than another? First with regard to locality. When the irritant arrives in one definite spot—e.g., pollen on the mucous membrane, or food in the bowel—we shall naturally find symptoms arising in that area; they will only become general if the irritant is absorbed into and distributed by the blood. But when the poison is broadcast by the blood why should the symptoms be localised? Or, if you like to put it so, why are certain tissues sensitised and others not by the universally distributed poison mixture? No doubt there are factors here that we know little or nothing about; but very frequently indeed it is possible to discern trauma as a predisposing cause. Angioneurotic œdema is curiously and capriciously localised; no doubt the lips, eyelids, and to a lesser degree the tongue and throat offer special facilities for œdema; in waking hours these parts are always on the move; sometimes, too, there are angioneurotic swellings of the fatigued fingers of typists; and though this is perhaps not "trauma," yet one's mind plays with the idea of histamine. But, putting these particular swellings aside, the remainder seem to arise where there has been damage done, where the skin has been rubbed by the corsets or the braces; one patient described how an angioneurotic attack began at the point where a jagged tooth was scratching the side of his cheek. Eczema notoriously comes on in areas exposed to damage from wind, from washing, or from sweat. Cases of epilepsy which are clearly connected up with these other symptoms are frequently reported as only arising after "the baby was dropped on his head," or "after the old gentleman tumbled down the stairs"—these accidents furnishing the trauma. In migraine it looks very much as if eye-strain was often the localising factor. In angioneurotic and urticarial cases sometimes the patient will only have migraine accompanying these symptoms when there is an œdema of the scalp, suggesting that there is perhaps an œdema occurring on both sides of the skull bone. Lastly, asthma shows frequent traces of trauma, since it is reported so often as only occurring after bronchitis, pneumonia, or having been gassed; up to that time the patient had experienced merely migraine or urticaria.

The Timing Factors.

The timing of the various symptoms depends very largely, of course, upon the arrival of the foreign

irritant. People get hay-fever in June, not in December; they get food sickness 20 minutes after swallowing the specified food; an attack of cat asthma may depend upon the presence of a cat (though the dust of a room in which a cat has been is equally provocative). The commonest time for asthma to commence is in the night, usually on waking—that is to say 6 to 8 A.M.; this is due, no doubt, to the recumbent position and the consequent congestion and collection of secretions. It seems probable that these night asthmas are usually bacterial sensitisations; but the whole question of night asthma needs working over.

Adrenalin or pituitrin will lessen or stop attacks of all the symptoms we have been considering, and will often do it so dramatically as to suggest that the endocrines have been playing a large part in determining the onset or cessation of attacks. If one works through all the endocrine preparations on the market, testing them, for example, on the Prausnitz reaction, only two of them—adrenalin and pituitrin—will check the urticaria, and none of them will hasten or accentuate the reaction.

Nerve reactions and the psychical state of patients play a striking part—in the unphilosophical language of the patient they "cause the attack." Coming into a bright light, changing from hot to cold atmospheres, any smell, "even the smell of my dinner," any excitement, such as watching a dog-fight, hearing of a sudden death, emotional music, may easily precipitate an expected attack. When once an attack has been so caused, then suggestion comes into play. Suggestion, for example, may start an attack of hay-fever by the smelling of an artificial rose, or by the vivid description of a place where an attack has been produced previously. This psychical factor is so important that it is worth accentuating by an example. A lawyer experienced his first attack of urticaria during the extreme annoyance of just missing a railway train, and thereafter always had an attack when giving evidence in the witness-box; his first attack of angioneurotic œdema occurred while watching a particularly harrowing cinema film. No wonder the word "neurotic" gets emphasised in such cases; and yet both the urticaria and the angioneurotic œdema were completely stopped by treating his sensitisation. Naturally the psychologists are not slow to explain the whole syndrome from their point of view; they will claim that there is a specific trauma provocative of hay-fever, another one provocative of asthma, another one of angioneurotic, &c.; and one may grant to them that psychical influences may affect the area selected for attack—e.g., the lungs, skin, gut. So far as a non-psychologist may venture an opinion 100 hay-fever patients are (at any time other than midsummer) just as well balanced mentally as 100 doctors or 100 railway porters. This will seem unconvincing to the Freudian, and I refer him to the Prausnitz reaction. Here you have the trouble arising in the selected area of your experimental man; certainly the psychological apparatus has not been transferred from the original owner of the serum. And to clinch the matter we find that emotion in the experimental man at the moment of the experiment will profoundly affect the result of the reaction. It is convenient at this point to emphasise the fact that no variety of the asthma syndrome is demonstrable in the lower animals.[1] Also it is impossible to produce any variety of the Prausnitz reaction in them by injecting sensitive human serum, together with the appropriate foreign irritant. This failure is so striking as to make one suspect that it is perhaps the psychical factor which is wanting. The whole question needs further work, though it has received much already.

[1] Dr. Freeman mentioned that he had been trying to get positive evidence on this point for the last three or four years, and had uniformly failed, and that if anyone could help with facts they would be much appreciated. It was necessary, of course, to get much more definite evidence than that a dog was frequently sick, a horse had trouble with its breathing, or that an ox repeatedly sneezed or had urticaria.

Dr. Freeman concluded by saying that trauma endocrine secretion, and the psychological state wer important but secondary factors. The underlyin mechanism behind all the varied symptoms unde discussion was the inherited immunological kinl This connected them all just in the same way tha the incapacity to face tubercle bacillus immun logically connected together lupus, phthisis, tube culous cystitis, arthritis, meningitis, and so o In fact, they were all one disease.

MEDICAL WOMEN'S FEDERATION.

AT a meeting of this Association held on Jan. 24t Miss E. BOLTON, the President, in the chair, D SIBYL R. EASTWOOD related the results of an invest gation into the

Gastric Secretion and Other Digestive Factors in Rosace

Dr. Eastwood defined rosacea as essentially chronic congestion of the facial skin, affecting mainl the central two-thirds of the face and leading t permanent vascular dilatation. Papules and pustule eczematous scaling, ocular lesions, hypertrophy of th subcutaneous tissues leading to rhinophyma, thoug seen in varying degrees in the clinical picture, were t be regarded as complications of the underlying vascul condition. The eyes were affected far more frequentl than appeared from the literature on skin disease Since Arlt described a case in 1864, there had bee constant reports of cases in ophthalmological journal and Dr. Eastwood explained this discrepancy fir as due to rosaceal keratitis occurring often in mi forms of facial rosacea, and secondly to the great importance attached by patients to a conditio affecting their eyesight than to their appearanc It was not until the recognition, even now not genera of the relationship between the two that the cas had been freely interchanged between the eye ar skin departments of hospitals.

Dr. Eastwood had been led to rosacea by her intere in the digestive system, and had hoped to obtain series of patients with achlorhydria or extren degrees of hypochlorhydria, as Barber and Ryle ha reported this anomaly of gastric secretion as prese in as many as 7 the 12 rosacea cases examin by them. In a series of over 50 cases of rosace seven of whom had ocular complications, Dr. Eas wood had found that digestive disturbance w present in nearly 90 per cent., that it was almo always "functional" in the sense that no orgar lesion of the gastro-intestinal tract could be demo strated. Fractional test-meals had been given to patients, and 9 per cent. had shown achlorhydr 24·5 per cent. hypochlorhydria, and 15·5 per cen low normal curves, thus agreeing very closely wi Brown's results in a similar series published in 192 These results corresponded closely with those fou in chronic arthritis and chronic cholecystitis by oth observers. Flatulence, constipation, flushing aft meals, and capriciousness in diet had been t commonest symptoms. From the X ray examin tions made in many of these cases, it appeared th some degree of hypotonicity was common, thou by no means universal. Marked dislike of meat h not been correlated with low acid secretion and h occurred equally with high normal and hyp chlorhydria curves—a point of much physiologi interest. Focal sepsis had been found in many cas Dysfunction or disease of the female genital orga had only been found in a few cases and as these h been cervicitis they fell into group of focal sepsis. T majority of the patients had had low systolic blo pressures. Whatever the type of digestive disturban its effective relief had been accompanied by relief the rosacea. Hydrochloric acid in drachm doses wi meals had had an almost magical effect in t patients with low or absent acid secretion, but had also proved useful where no deficiency had be shown. Carbohydrate excess in diet had been fairly constant finding, and its correction a pote factor in successful treatment.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society, held on Feb. 2nd, Dr. DONALD HALL, the President, in the chair, a paper was read by Dr. L. A. PARRY on the

Trial of Mary Blandy

for the murder of her father by poisoning with arsenic. Dr. Parry first referred to various earlier cases of murder by poison—the Glenconner case in 1580, that of Henry Robson who poisoned his wife in 1598 by the introduction of arsenic into the vagina, and the Overbury mystery of 1615—and mentioned the inquest on Miles Sindercome who, for high treason, had been condemned to be hanged on the gallows till he be half dead, and then to be cut down and his entrails and bowels taken out, and burnt in his own sight, and who had committed suicide by poison to avoid this dreadful punishment. Sir Richard Napier and Dr. Fern had given very vague, indefinite, and unsatisfactory evidence.

Dr. Parry pointed out that the trial of Mary Blandy was the first case of murder by poison, so far as he could ascertain, in which medical evidence was given to prove the cause of death. The girl had been accused of the murder of her father in order to obtain his money and marry her lover, from whom she had received some powders which she gave to her father. According to her statement she had believed that she was giving him a love philtre to make him like her lover more. The evidence for the prosecution proved that this was not so, that she had deliberately poisoned her father, with full knowledge of her act. The chief medical witness had been Dr. Anthony Addington, the father of the celebrated statesman, Lord Sidmouth. His evidence showed that he had analysed some of the powders sent to Miss Blandy and that they had contained arsenic. But though a post-mortem had been carried out, no attempt had been made to examine the viscera for arsenic. The tests recommended at this time by the celebrated chemist, Dr. Black, of Edinburgh, had been few and not very different from those used at the present time. They had included a modified Reinsch's test. The best and most delicate test known at the present time was the electrolytic, which showed the presence of very minute quantities of the mineral. This test had first been used quantitatively in the trial of the Seddons in 1912. Miss Blandy had been found guilty and executed at Oxford. The method of execution at that time had been different from that of to-day. The criminal, or as was more often the case, the batch of criminals, had been drawn in a cart to the place of execution through a crowd of morbid sight-seers, and then, one after the other, had the halters adjusted. The cart in which they had stood, or the ladder which they had climbed, was removed and they had been left to die of strangulation. This had often taken quite a considerable time. Occasionally the executioner would take pity on the poor victims, and hang on to the legs, thus shortening the death agony. To-day the death factor was not strangulation; the sudden jerk of the fall caused a fracture-dislocation of the cervical vertebræ, and death was instantaneous. The knot of the rope was fitted close to the ear, as in this way it had been found that the dislocation was more certainly caused. The guilt of Mary Blandy had usually been accepted by the many who had written on her case. Dr. Parry mentioned a letter written by her just before her death, and a speech made by her on the scaffold, as was the custom at the time. In both of these she had firmly declared her innocence of any wrongful intent in giving the powders to her father. "All this is true, as I hope for eternal salvation and mercy from Almighty God, in whose most awful and immediate presence I must soon appear." Whatever one's views of a future state, it was admitted by all that the last few hours of life are very solemn ones. It was difficult to understand how Mary Blandy, if she were the wretched parricide pictured at her trial, could have uttered such words a few moments before death. Was she really guilty?

EDINBURGH OBSTETRICAL SOCIETY.

A MEETING of this Society was held on Jan. 11th with Prof. R. W. JOHNSTONE in the chair. A paper was read by Mr. DAVID LEES on

VULVO-VAGINITIS,

in which he analysed the cases which had come under his observation in a period of five years, 1922–27. A total of 146 cases were dealt with and were divided into the following age-groups:—0–1 year, 7·4 per cent.; 1–5 years, 39·2 per cent.; 5–10 years, 44·9 per cent.; 10–15 years, 8·4 per cent. The incidence of vulvo-vaginitis in Edinburgh, said the lecturer, had been augmented by a recent epidemic in a children's institution where it had spread rapidly and proved very contagious. In the great majority of cases (40 per cent.) the source of the infection could not be ascertained; in 13 per cent. of the cases the patients were reported to have been assaulted, but in only a very small proportion was this proved; 15 per cent. of the cases were epidemic in origin, and in 32 per cent. the infection was traced to others in the family. Mr. Lees described the symptoms and signs of the disease and drew attention to the frequency (99 per cent.) of involvement of the urethral canal in acute cases. Every vaginal discharge in children must be looked on with suspicion and treated as if of gonococcal origin, until at least three bacteriological tests had proved negative, under conditions favourable for the detection of the gonococcus. In chronic cases repeated films and cultures were necessary and in resistant cases direct films or cultures must be taken from the cervix. In 73·7 per cent. of the cases gonococci had been found; in 6·6 per cent. gonococci and other organisms, and in 19·7 per cent. secondary organisms only. In acute cases the gonococcus had been demonstrated in over 98 per cent. of cases. The more acute signs of disease disappeared rapidly with treatment, but the parents should always be warned that a long time was required to eradicate the disease and that relapses were apt to occur unless the patient was kept under treatment. Hospital treatment and isolation of the patient from other children was recommended wherever possible.

Treatment.

The chief therapeutic measures recommended were hot antiseptic and alkaline hip-baths and daily lavage of the vagina and urethra. In older children the vagina was dried by swabbing through a speculum and the parts were dusted with dermatol powder; in younger children, when a speculum could not be introduced through the hymen, instillations of an antiseptic dissolved in glycerine were recommended. The antiseptic preparations recommended were ¼–1 per cent. picric acid in glycerine; ¼–1 per cent. silver nitrate in glycerine, and ¼–½ per cent. chloramine-T in glycerine. The instillations were supplemented by the use of small medicated bougies of these and other substances. If it were not possible to irrigate the urethra small urethral bougies, with chloretone added to ease the pain, were inserted daily. Repeated changes of the antiseptic were advised and it was recommended that in every case the vulvar surface should be left as dry as possible by dusting it with a compound dermatol powder. Efficient treatment depended more on the meticulous care with which it was applied than on the medicament used. In every case it was essential:—

(*a*) To establish good drainage from the urethra, vulva, and vagina.

(*b*) To produce a slight hyperæmia of the infected parts by hot hip baths and hot vaginal douches.

(*c*) To use a sterile all-glass catheter, with lateral perforations, so as to spread the antiseptic over the vaginal wall during the douche and prevent the infection being carried to the cervix.

(*d*) To dry the parts subsequent to douching or alternately to instill the vagina with an antiseptic solution in glycerine.
(*e*) To treat the urethra in every case.
(*f*) To examine and treat the rectum if infected.
(*g*) To prevent the child from conveying the infection to others and to its eyes.

Adjuvant methods of treatment were used in both acute and chronic cases, and of these detoxicated and autogenous vaccines proved most serviceable. The child tolerated and responded well to vaccine therapy.

In the series of cases reviewed the following complications arose :—

	Per cent.
Gonococcal infection of the eye	8·3
Infection of the Fallopian tubes and pelvic peritoneum	5·5
Infection of the rectum	2·7
Non-specific ulceration of the vulva	1·8
Acquired syphilis of the vulva	1·8
Cystitis	0·9

No cases of arthritis were met with. Coincident syphilis was met with in 7·5 per cent. of all the cases.

In coming to a diagnosis of cure it was essential to observe cases over long periods, and to examine repeated films during this period of observation. The standard of cure aimed at in every case should be :—

(1) Clinical cure and no sign of clinical relapse after suspending all local treatment. Local treatment must be carried on for at least three weeks after apparent clinical cure.
(2) Bacteriological cure in three successive smears taken at intervals of one week during treatment, and in three subsequent weekly tests taken after suspending treatment.
(3) Clinical and bacteriological tests at intervals of one month over a period of three months subsequent to the attainment of (1) and (2).
(4) If there was any doubt as to the clinical condition or bacteriological reports, administration of a provocative vaccine and a repetition of the tests both by direct film and by culture was indicated.
(5) If there was neither clinical nor bacteriological evidence of disease during a period of three to four months after cessation from all treatment the case might be considered cured.

In trying to attain this standard the following results were obtained in the series of 146 cases reported :—

Average duration of treatment and tests for cure of gonococcal cases in those now completed (87 cases)	7 months
Average duration of treatment and tests for cure of vulvo-vaginitis cases not proved gonococcal (21 cases)	2 ,,
Cases still under treatment, but presumed cured, which have now been under treatment and tests for cure for a period of five months	13 cases
Cases still under active treatment with infection still present	18 ,,
Cases which defaulted while still showing signs of infection	7 ,,

Puerperal Hæmorrhage.

Dr. G. D. KENNEDY then gave clinical notes of three cases of puerperal hæmorrhage. These cases were of interest as the bleeding was very severe in each case and did not occur until after the tenth day of the puerperium, the dates of occurrence being the tenth day, fourteenth day, and sixth week respectively after delivery. No definite cause was found, even after thorough examination under chloroform and curettage. In each case, however, a retroversion was present, which was the more interesting as on dismissal from the maternity hospital in all cases the uterus was anteverted. In no case was there any apparent infection during the puerperium. In two cases the mother was not nursing her baby and therefore the hæmorrhage might have been the return of an early menstruation. Dr. Kennedy thought that as retroversion was common to all it must have something to do with the hæmorrhage. He could, however, find no record anywhere of a simple retroversion in the puerperium causing so severe a hæmorrhage.

WESTERN OPHTHALMIC HOSPITAL.—This hospital, in the Marylebone-road, London, is to be rebuilt. The existing building is said to have been erected by George III. as a country residence for his children. It is in bad condition and extremely crowded and inconvenient. The proposed new building will cost £40,000.

Reviews and Notices of Books.

SAHLI'S CLINICAL METHODS.

Lehrbuch der Klinichen Untersuchungsmethoden für Studierende und praktische Aerzte. Seventh edition. By Prof. H. SAHLI, Director of the University Medical Clinic in Berne. Vol. I., first half. Leipzig and Vienna: Franz Deuticke. 1928. Pp. 496. M.26.

THE new edition of Sahli ends off in the middle of a sentence on p. 496, but that will not prevent the initiated from reading the volume up to that point with the liveliest interest, for the author is no mean stylist and among the greatest living authorities on physical examination. He admits frankly that literary composition is to him an absorbing interest, applying to himself the following words of a popular German novelist: "The reader may smile over it but for us authors writing is a madly exciting business, a voyage in the tiniest boat on the high sea, a lonely flight through infinity"; and although the publisher may suffer—the author mentions "unending corrections" in his manuscript—the reader is blessed in the assurance of knowing exactly what Sahli wishes to tell him. At first sight his book may seem to be the ordinary collection of bedside methods gleaned without critical faculty from all sources, but study will soon discover that Sahli's methods have been worked out largely by himself and his staff at a clinic run on continental lines and visited by graduate students from all parts of Europe and indeed of the world. Subjectivity enough will be found in the present volume, for Sahli expresses a horror at the practice of setting down contradictory views without indication of the writer's bias, for "in medicine," he writes, "pretty much everything is stated which it is possible to state," and such roughage he regards as unsuitable for student diet. The present instalment of the book covers the examination of the patient's general condition, of his skin, the determination of temperature, the behaviour of respiration, and the various methods of investigating the circulatory system. The section on hæmodynamic methods is a monograph in itself. Sahli holds very precise views in regard to the mechanism of the circulation and is prepared to justify them by exact methods of physical examination; in his hands the hæmobolometer has given interesting results. To these we may return when publication is complete, and may content ourselves now with recommending every student and practitioner of medicine who can read German to make acquaintance with physical examination through Sahli's eyes and fingers.

EXPERIMENTAL BIOLOGY.

Factors Affecting the Distribution of Electrolytes, Water, and Gases in the Animal Body. Lectures delivered at Rutgers University under the Luther Laflin Kellogg Foundation. By DONALD D. VAN SLYKE, Ph.D., Sc.D., Member of the Rockefeller Institute for Medical Research. London: J. B. Lippincott Company. 1927. Pp. 6. 10*s.* 6*d.*

THIS monograph deals with factors affecting the distribution of electrolytes, water, and gases in the animal body. The main theme of the work is based upon Prof. L. J. Henderson's conception of blood as a physico-chemical system, and the method of interpreting the reactions of this system is the nomographic method. Types of nomograms used in the work are in the main Cartesian, but some of the results are expressed in the form of d'Ocagne alignment charts. The subject is extremely complicated, and can only be followed by those familiar with this type of work. The volume is of definite value in that it collects under one cover the recent work of D. Van Slyke and his colleagues, and at the same time forms a very valuable extension to Prof. Henderson's investigations.

PHYSIOTHERAPY.

A Practice of Physiotherapy. By C. M. SAMPSON, M.D., Formerly of the Physiotherapy Service, Walter Reed U.S. Army General Hospital, Washington, D.C. London: Henry Kimpton. Pp. 620. 45*s.*

THIS book is the successor to the author's "Physiotherapy Technic," which was published in 1923. Many additions have been made, including a therapeutic index. The author writes most fully on diathermy and high-frequency currents; about one-fifth of the book is devoted to these subjects. Static electricity is fully considered in a chapter of 17 pages, while 60 pages are devoted to ultra-violet light therapy. Other forms of electrotherapy and physiotherapy are briefly considered. Special chapters deal with acute gonorrhœa in the male, peripheral nerve wounds, arthritis, locomotor ataxia, pyorrhœa alveolaris, and hay fever.

The author writes fully on technique and gives detailed descriptions of the methods which he has found most satisfactory. On certain matters his teaching is peculiar. He distinguishes two methods of applying diathermy, one for procuring the stimulating effects of heat, the other for producing sedative effects. The former he recommends for pathological conditions such as non-uniting fractures. He insists that diathermy currents should be delivered from the machines at a higher voltage than that which is customary in many forms of apparatus now constructed because, he says, currents at relatively low voltage produce little heat in the deepest parts of the body. He gives description of an occasion when he was treating the prostate of a medical friend with a high-voltage diathermy machine. The current had reached a value considerably lower than that which produced the maximum bearable heat when low-voltage currents were used, but was sufficiently objectionable to cause the patient to protest with vigour. Dr. Sampson insists on the importance of learning and practising correct technique and the futility of first connecting the patient to the source of energy and then setting the machine in operation.

The book is written throughout in a breezy and colloquial manner. It is scarcely suitable for the beginner, but the more advanced reader will find much that will interest him and still more that will amuse him. Dr. Sampson has had wide practice in most forms of physiotherapy and he writes almost entirely from his own experience.

Physical Treatment in Diseases of the Eye, Ear, Nose and Throat. By ABRAHAM R. HOLLENDER, M.D., Attending Oto-laryngologist, American Hospital of Chicago; and MAURICE H. COTTLE, M.D., Attending Oto-laryngologist, Illinois Masonic Hospital, Chicago. London: J. and A. Churchill. Pp. 307. 21*s.*

Dr. Hollender and Dr. Cottle, who are in charge of the oto-laryngological departments of two large hospitals in Chicago, have acquired considerable experience in the use of physical agents, in the treatment of diseases of the eye, ear, mouth, throat, and nose, and have incorporated their findings in this comprehensive work.

In the first part they explain briefly the meaning of the technical terms used, and the nature and properties of the various agents. The next two parts deal respectively with the treatment of diseases of the eye and ear. The treatment of diseases of the nose and accessory sinuses is then described, and subsequently the diseases of the mouth, pharynx, and larynx are considered. Finally the authors deal with borderline diseases; these include headache, hyperæsthetic rhinitis, seasonal hay fever, asthma, and certain diseases of the eye, ear, and nose, which may have a causal relationship to disturbances of the endocrine system.

Physical agents have been extensively employed in recent years in the treatment of diseases of many regions of the body, but in oto-rhino-laryngology and ophthalmology little attention had hitherto been directed to physiotherapy in spite of the need for more effective methods of treatment. By careful clinical investigations Dr. Hollender and Dr. Cottle have shown the help that may be derived from diathermy, ultra-violet light, the galvanic current, and other physical agents in the treatment of diseases which respond badly to certain therapeutic agents. In early cataract negative galvanism is recommended as well as diathermy, and it is claimed that considerable benefit can be derived. In selected cases of glaucoma the authors state that diathermy and galvanism may prove of inestimable value. They have investigated the effect of diathermy on the normal eye, using tonometers, one eye being subjected to the heat and the other serving as a control. A lowering of tension was demonstarted after an application of diathermy for half an hour.

The authors speak with restraint throughout the book and do not recommend physiotherapy where surgical or medicinal treatment can produce satisfactory results. The volume is well printed and illustrated, and its contents form a valuable contribution to the subjects in which the writers specialise.

ORGANIC INHERITANCE IN MAN.

By F. A. E. CREW. London and Edinburgh: Oliver and Boyd. 1927. With 36 text figures. Pp. 214. 12*s.* 6*d.*

William Withering (1741–1799), to whom, among other things, we owe the introduction of digitalis to the pharmacopœia, was a man of implacable curiosity and industry. It is appropriate that one of like spirit should have been chosen to give the first Withering memorial lectures in the University of Birmingham. Out of them has emerged this excellent book. It is useful, firstly because it gives a particularly clear account of the theory of Mendelian inheritance and the genes on which it may be assumed for the present to depend, and secondly because it is written with special reference to human abnormalities of which more than 50 pedigrees are given. Medical men are situated in a position of peculiar advantage for collecting the further data which are so much needed; we hope they will read the book and become sufficiently interested to help to forward the work it outlines.

AMERICAN ILLUSTRATED MEDICAL DICTIONARY.

Fourteenth edition. By W. A. NEWMAN DORLAND, M.D., F.A.C.S. London and Philadelphia: W. B. Saunders Company. 1927. Pp. 1388. 35*s.*; or with thumb index, 37*s.* 6*d.*

THE fourteenth edition of Dorland does not differ in any essential features from the thirteenth, which was published two years ago, except that the name of Dr. E. C. L. Miller, professor of bacteriology and biochemistry in the Medical College of Virginia, appears on the title-page as collaborator with Colonel Dorland; but we learn from the preface that many definitions have been rewritten in accordance with the latest terminology, and over 2000 new words have been added. Therewith the volume has gained some 44 pages in length although the price remains the same. It would be a forlorn hope to try to find errors of omission or commission in this edition; we take it kindly that each time we have called attention to a missing word the editor has supplied it in the next following issue of the dictionary—thus now, and at length, the reader is properly orientated in the identities of Schwarz, Schwartz, and Schwartze. The only feature that possibly calls for criticism is the selection of line drawings, of which more than a hundred have been added to the present edition. Various kinds of flies and moulds are now illustrated in this way, and these may have some practical value, but we doubt whether a diagram of a gastro-enterostomy, or a photograph of varicose veins of the leg is worth the space allotted. It would be a pity, we think, to turn an admirably complete dictionary into an imperfect encyclopædia. However that may be, we doubt not that Dorland will maintain its popularity.

UNIVERSITY COLLEGE.

Centenary Addresses by the late E. H. STARLING, OLIVER LODGE, R. W. CHAMBERS, J. ROSE BRADFORD, J. A. FLEMING, J. M. COLLIE, G. K. CHESTERTON, J. E. G. DE MONTMORENCY, Bishop TEMPLE, H. A. L. FISHER, GREGORY FOSTER, and MARY BRODERICK. University of London Press. 1927. Pp. 303. 12*s.* 6*d.*

AMONG the other celebrations of the centenary of the foundation of "the accursed Academy in Gower Street" were twelve orations delivered by various distinguished people, some of them surveying the progress of a hundred years in their several branches of knowledge, others commemorating the establishment and maintenance of freedom in teaching and learning. They can be bought separately, but it was a happy idea of Prof. Chambers to bring them together in one volume; in it one may read of most of the aspects under which University College has steadfastly upheld university education in London. It is, perhaps, not quite fair to detach them from the settings in which they were originally delivered, but as they stand in print those of Prof. Chambers and the Provost stand out in the humanities and those of Sir Oliver Lodge and Prof. Fleming in the sciences; Mr. Chesterton is not at his best, and the volume ends with an admirable contribution from Dr. Brodrick on "those hussies."

EXPOSURES OF LONG BONES AND OTHER SURGICAL METHODS.

By ARNOLD K. HENRY, M.B., B.Ch. Dub., F.R.C.S.I. Bristol: John Wright and Sons, Ltd. Pp. 80. 10*s.* 6*d.*

THIS little volume bears in every line the marks of original observation. Whether other surgeons will or will not agree with the methods described is a matter of secondary importance; they are invariably original and suggestive. The book covers a wide range of subjects and includes exposure of the long bones, new methods of exposing the vertebral and subclavian arteries, the excision of the sympathetic ganglion for angina, and an entirely new technique for reaching the pituitary gland. It thus compresses into small compass a large amount of useful and original observation.

ENCEPHALOGRAMS IN CHILDREN.

Uber Encephalographie im Kindesalter. By Dr. TH. BREHME, Assistant, Heidelberg University Children's Clinic. Berlin: S. Karger. Pp. 50. M. 4.20.

THIS monograph is an important addition to the literature on the subject of encephalography. Of the three possible routes of air injection into the brain cavities (ventricle puncture, suboccipital puncture, and lumbar puncture) the author has confined his attentions to lumbar puncture, and by carrying out the procedure in 45 children has shown that it is a safe and successful method. He found that the after-effects were slight and transient; temporary headache was the rule, but there were no instances of collapse or severe symptoms. An anæsthetic was rarely necessary; his technique is simple. The 45 radiograms which he publishes show that the ventricles can be perfectly outlined by this method and that valuable indications may result therefrom. Surgeons in this country appear to favour direct ventricular puncture owing to the certainty and to the information which may be gained from the actual operation, especially in internal hydrocephalus. In the latter condition, when due to occlusion by meningitis or tumour, the lumbar method naturally fails to outline the ventricles, but the author claims that failure to outline is, in itself, pathognomonic, since there is no record of failure to demonstrate the ventricles in normal cases by his method.

We commend the monograph to the attention of neurologists, and to radiologists interested in the interpretation of encephalograms. The X ray appearances are sometimes difficult to interpret; sometimes such definite variations from the normal occur that diagnosis is confirmed. The inclusion of normals is helpful. Dr. Brehme has done a valuable piece of straightforward research work, which may well give an impetus to wider investigations along the same line.

TISSUE CULTURE.

Gewebezüchtung. Second edition. By ALBERT FISCHER. Munich: Müller and Steinicke. 1927. Pp. 508. M.37.50.

To all engaged in tissue culture work this book is a mine of information. All aspects of the subject are considered and a really good bibliography is appended. After an introductory and historical chapter the composition of culture media and their preparation are described, and an account given of such work as has been done to investigate the food conditions essential for growth. A useful summary follows. The technique of cultivation is described in detail so clearly that no worker should fail to obtain results if he follows the directions given. The rest of the book treats with the same wealth of detail so far as it is known, the physiology of growth in vitro, the minute anatomy of the cell, the cultivation of different tissue cells outside the body and their behaviour under artificial conditions, and many experiments which have been made to elucidate the problems of pathology and immunity, and neoplastic growth. We have not found elsewhere so much information upon tissue culture collected together in one volume.

JOSEPHINE BUTLER.

Her Work and Principles and their Meaning for the Twentieth Century. By Dame MILLICENT FAWCETT. London: Association for Moral and Social Hygiene. 1928. Pp. 164. Cloth, 2*s.* 6*d.* paper, 1*s.* 6*d.*

IN Parts I. and II. of the League of Nation's Experts' Report on the Traffic in Women and Children, the campaign associated with the name of Josephine Butler is briefly referred to, but as she died over 20 years ago it is possible that to many her name is the only knowledge which they possess of her. Yet she was for a period one of the most talked about women in England, while she laid the foundation for social reforms upon which, and none too soon, beneficial changes have been erected. Dame Millicent Fawcett's book is published in recognition of the centenary of Josephine Butler's birth. It sets out her family life sufficiently to show the influence of early years upon her in originating and confirming her religious impulses and in dowering her with pity and courage. But she was about 40 years of age when her name became prominent. Her husband was holding an educational post in Liverpool and while there she helped to establish homes and refuges for fallen women. This led to her coöperation in the agitation which had just begun for the repeal of the Contagious Diseases Acts, an agitation in which she became the most prominent, the most admired, and the most abused protagonist. She gave evidence before the Royal Commission which was appointed in deference to the strong feelings aroused by the representations of herself and her colleagues, and was energetic in denouncing the traffic in young girls between Belgium and England, and the working of organised prostitution in India. The official documents of the League of Nations have now justified many of the contentions, 40 years old, of Josephine Butler and those who coöperated with her, like James Stansfield, Daniel Cooper and William Stead. Dame Millicent Fawcett closes her book with the quotation: "The seed which she has sown can never die," and there is no doubt that the general arguments that were used formerly in behalf of State recognised prostitution would never be employed to-day, even though there is medical support for certain antivenereal measures, which she might have reprobated. We have here a pious story movingly told

THE LANCET.

LONDON: SATURDAY, FEBRUARY 11, 1928.

THE INTERNATIONAL OFFICE OF HYGIENE.

THE International Sanitary Convention of Paris, 1926, placed a number of important new duties on the Permanent Committee of the International Office of Hygiene, and the steps which that Committee is taking to fulfil those duties are of interest. The Convention lays down agreed lines of principle and international practice in dealing with the prevention of transmission of plague, cholera, yellow fever, typhus, and small-pox at sea and land frontiers. A primary requirement for this purpose is intercommunication of facts and figures regarding the prevalence of these diseases. The methods prescribed to this end in previous conventions, which were cumbrous and often ineffective, are now to be changed, and the new system makes the International Office in Paris the responsible centre for the collection and distribution of the desired information. The problem which has been presented to its committee and director in this matter is, however, none too easy. In certain cases, rapidity of transmission is the first consideration, and all modern means, like cables and wireless, broadcasting, or air mails may have to be called into service, and special codes utilised. On the other hand, the Convention is world-wide in its application, and the mechanical use of these methods to inform every country of every kind of foreign outbreak or epidemic would be futile and extravagant. It has, moreover, to be remembered that the Convention affirms the principle that information as to foreign outbreaks does not carry with it any necessity of action, and that it rests with each country to apply the specified measures according to its own appreciation of the needs of the particular case. Hence information in the form of detailed communiqués regarding the circumstances in which an epidemic disease has appeared, its type, and the action taken, are often of greater ultimate importance than telegrams of notification figures, even though it necessarily arrives more slowly.

A memorandum relating to the work of the last session of the Permanent Committee of the International Office at Paris, which we have obtained from its director, Dr. POTTEVIN, shows that the solution is being sought by a system of utilising "regional" offices from which information in detail can be sent rapidly to the interested countries in the region, and be summarised in code for periodic transmission to the Paris centre. Here the Committee has had ready to its hand a clause in the new Convention which empowers it to make agreements with the League of Nations Health Organisation and similar international health bodies. Great success has attended the system by which the League of Nations, from its office in Geneva, and from its branch office for the Far East at Singapore, now collects official returns regarding infectious diseases from many public health administrations, and publishes them in "Epidemiological Intelligence Bulletins," which are already widely known and used. To avoid duplication, these bulletins are to be recognised as an official means of transmitting information supplied under the International Convention, and will include special communications supplied to the regional bureaux from Paris. For the Americas, a somewhat similar service is already undertaken by the Pan-American Sanitary Bureau at Washington, and the last Pan-American Conference, held at Lima in October, accepted the proposal that it should in future also act for the Paris office under the Convention. Another and equally valuable agreement has been negotiated with the International Quarantine Board at Alexandria, which will work as a regional bureau for countries of the Near East and the Levant—a regional system whose value was demonstrated last year in connexion with the outbreak of cholera in Iraq and Persia. Supplementary arrangements, for example with the Australian Government for collection and codification of information from islands in the Pacific Ocean, are also being considered. The requirement that ships should be regularly overhauled at approved ports, in order to ascertain if they require measures of "deratisation"—the term, in French at least, seems to have become official—entails on the International Office of Hygiene the duty of giving rulings, after consultation between its delegates, on various details where a common practice must be adopted in the interests of shipping. Among these is the form of certificate of "deratisation" or "exemption from deratisation" which will in future have to be included among the ships' papers. A convenient stock form for this purpose, based on the United States model, has been recommended. The Office has also decided to undertake the publication of an annual directory relating to quarantine measures, sanitary equipment of ports, and like matters throughout the world—a volume which promises to be of great convenience to administration and shipping. All this preparatory work will greatly facilitate the smooth working of the new Convention when the formalities of its ratification have been completed and it is in full operation. Allied questions, also considered, were proposals for the official recognition of ships' doctors in quarantine work, the use of wireless to convey messages regarding the health of ships to the next port of call, and the instructions and assistance in medical emergencies which can be furnished to the masters of vessels not carrying a doctor. On the last-named subject, which is now also receiving attention from a special committee of the British Medical Association, the committee of the Paris office is collaborating with the League of Red Cross Societies.

During the same session the Permanent Committee according to the terms of the Geneva Convention of 1925, advised the Health Committee of the League of Nations on the additional narcotics which should be scheduled as drugs of addiction, and decided to deal at an early date with the evidence which is being collected regarding the undesirable use of benzoylmorphine and other morphine esters. The most interesting part of its proceedings, however, were, as usual, the contributions from the different official delegates or rapporteurs on new features of epidemiology or administration in their respective countries, most of which ultimately appear in its monthly publication, the "Bulletin of the Office International d'Hygiène Publique." The reports on the prevention of beri-beri in the Dutch East Indies by means of vitamin extracts, on the antituberculous vaccination of adults in Norway by B.C.G., on changes in Japanese administration against venereal diseases and for the control of medicaments, and on the new insurance system against tuberculosis which is being established in Italy are a few examples of the utility of these periodical conferences. An instructive account was given by Dr. N. M. JOSEPHUS JITTA of the progress

of investigations in Holland into the occurrence of encephalitis after vaccination, a subject on which the Committee will shortly receive further enlightenment from a special associated commission on small-pox and vaccination questions appointed by the League of Nations Health Organisation. The delegate from South Africa referred to recent work establishing the viability of the plague bacillus in the flea, apart from a human host, for as long a period as three or four months, while the British delegate presented the experience of the Liverpool port sanitary authority in gauging the degree to which ships are infested by rats. The facts supplied as to recent cholera extension included the estimate of about 15,000 as the total deaths during its extension to French Indo-China in 1926—a figure which it is claimed would have been very largely increased but for the extensive and organised system of anti-cholera vaccination put in force in the infected areas. The results of the same vaccination, and of ingestion of bilivaccin, in India, and the apparent success of vaccination in preventing the extension of cholera in Persia were also described. The measures taken by the British authorities in Iraq to deal with the outbreaks which began last July in the ports of the Persian Gulf, and the value of the energetic action by which its progress up the twin rivers into the interior was checked, received special attention, as well as the question of the need for new methods of control to cope with the many new lines of communication which have been opened up in these Near Eastern countries. Reference may also be made, in conclusion, to an instructive communication from the Roumanian delegate regarding a widespread outbreak of epidemic poliomyelitis which affected that country during 1926–27, and to the accounts of yellow fever in Africa which are contained in the December number of the Bulletin.

FŒTAL ARCHITECTURE.

WE publish this week an account by Mr. VINCENT PATRICK of a case of thoracopagus which was admitted recently to St. Thomas's Hospital, and one of craniopagus which came a little later under the care of Dr. H. C. CAMERON at Guy's Hospital. Both cases have attracted public attention. From the most ancient times man has been fascinated and attracted by all departures from the usual or the normal, although when they become of frequent occurrence he accepts them as he accepts the rest of his environment. The very derivation of the word monster indicates quite clearly how the Romans regarded the birth of a child which showed any conspicuous abnormality, and the continued use of the word is to be deprecated. The term is entirely unscientific and has never been defined in a satisfactory manner. CHARLES DARWIN defined a monstrosity as some "considerable deviation of structure, generally injurious, or not useful, to the species," but such a definition is too vague to be regarded as acceptable and, indeed, it is time wasted to attempt a definition. It would be better to abandon the use of the term entirely, convenient and occasionally descriptive as it may be, and to refer to the individual cases by their appropriate designations. All such cases are examples of disordered or partially arrested growth, and they are of scientific interest in so far as they provide one avenue of approach to the study of normal growth. The problems which are presented by growth and differentiation are amongst the most difficult that confront the embryologist to-day, but the darkness with which they have been surrounded for so long is gradually being illuminated by experimental work, especially in the fields of embryolog and pathology. Until the processes of normal growt are understood and defined, we cannot hope to solv the allied problems of abnormal growth. It is true as we must all admit, that much has been an can still be learnt with regard to normal growth b the careful study of cases where growth has proceede in an abnormal manner, but the inferences to b drawn from such a study are robbed of much of thei value by our ignorance of normal processes. In th early stages of the development of the fertilise ovum there is apparently a brief period during whic it may be said that a very large number of the cell derived from the original ovum retain all th potentialities of the latter and, when transplante into favourable surroundings, they are capable o producing another embryo. When we consider th processes of abnormal growth, as exemplified by th occurrence of conjoined twins from time to time, w ought not to experience surprise that such a mistak should be possible; but bearing in mind th potentialities of the cells with which we have to dea we ought rather to marvel that Nature departs s rarely from the orderly and regular character of he course. That such is the case is due to the fac that the stage of unlimited potentialities of the cel is closely followed by a stage in which there organisation and control of their further growtl It has been shown for amphibian larvæ that the cel which lie in the dorsal lip of the blastopore exercis an important organising and controlling influence i the earliest stages of differentiation, and it is to the influence that the orderly progress of subsequer developmental changes is to be attributed..

That one group in a living mass of cells shoul exercise a regulating and controlling influence ov a neighbouring group, an influence which may b to some extent reciprocal, has been shown by th work of experimental embryology and tissue cultur Transplantation of the optic vesicle from its norma position to a site under the ectoderm elsewhere i the body has been repeatedly and successfully carrie out. The ectoderm over the transplant develops crystalline lens in the normal way, but no le develops on the side of the head from which the opt vesicle has been removed. Pure cultures of epitheli cells show no tendency to adopt a definite morph logical form until they are brought into contact wit fibroblasts, when they become differentiated into ren tubules, thyroid acini, and so on, corresponding t the source of the epithelium in the first place. It now well recognised that identical twins develo from a single ovum and that the complete cleava which separates the two must occur before an definitive embryonic area or disc can be determine The production of uniovular twins in man may b regarded as one of Nature's successful experiment but at the same time we must remember that what an experiment in man is the general rule in some oth mammals. In one of the armadilloes, for example, th fertilised ovum always gives rise to four separa embryos, which are all of the same sex. But would appear that the time period during which th experiment can be carried out successfully is relative short, and its delayed attempt results in th disastrous failures which are represented in teratolog by a large group of malformations. Experimentall it has been found possible to divide the fertilise amphibian ovum and produce twin embryos up the stage of the completion of the gastrula. Attemp to produce twin embryos experimentally at a lat stage have resulted only in the production of duplic tion of some part or parts of the body. The type

malformation depends in part on the plane and degree of cleavage and in part on the subsequent development of the two conjoined embryos.

Cases of craniopagus, in which both embryos develop normally, represent an attempt at the production of uniovular twins which has all but succeeded. The two are completely separated and perfectly formed, save that the two heads are joined together by their vertices, frontal, or occipital regions as the case may be, the brains being separate and acting independently of one another. Cases of omphalothoracopagus, on the other hand, represent attempts that have been less successful, and there is usually direct continuity of the two hearts, while the pericardial, pleural, and peritoneal cavities are common to both. In the two types, to which reference has been made, both twins develop symmetrically, but asymmetrical development may also occur. Embryologically there is no initial difference between symmetrical and asymmetrical conjoined twins. In the latter variety one embryo continues to develop in the normal way, but the development of the other is retarded and it remains in a more or less diminutive form, a parasite dependent on its autosite for its blood- and nerve-supply. It is a curious law of ontogeny that whereas in the early stages cleavage is the keynote to development and growth, subsequently structures which are situated symmetrically as regards the median plane or long axis of the embryo and which subserve the same functions show a very strong tendency to fuse with one another. The fusion of the two primitive heart tubes is a striking example of this tendency, and it is just possible that in cases of conjoined twins some of the connexions may be of this secondary nature. The relationship between conjoined twins and teratomata, if there be any, is quite uncertain. The subject is further complicated by the fact that teratomata of the sexual organs are not uncommon, especially in the female, whereas other somatic teratomata are very great rarities. Such a difference in relative frequency suggests the possibility that the two groups of teratomata may have totally different origins from one another. Fortunately, of the many forms of symmetrical conjoined twins, it is only those belonging to the ischiopagus, xiphopagus, and sternopagus groups that are likely to survive their birth by any prolonged period. Cases of craniopagus and ischiopagus must be kept lying down and they naturally fall an easy prey to any slight infection. Sir JOHN BLAND-SUTTON has recently drawn attention to the desirability of endeavouring to separate the autosite from its parasite in cases of asymmetrical conjoined twins,[1] and in view of the miserable nature of the existence which symmetrical conjoined twins may have to endure, it is not too much to say that it is the duty of the surgeon to attempt their separation, if he believes that there is any chance of success.

THE DISPOSAL OF THE DEAD.

STATISTICS which have been obtained through the courtesy of certain municipalities in England and Wales give striking information concerning the cemetery undertakings of the country. The figures have been furnished to the Cremation Society of England, and form the text of a valuable little book which has been published this week.[2] The Cremation Society addressed 198 municipal and burial authorities, of which no less than 166 replied to a questionaire in which the following information was required: the name of the cemetery or cemeteries under the municipal authority, the date of establishment, the area of land occupied or reserved, the capital expenditure on the undertakings, and the total interments up to the end of March, 1926. Further details asked for included the average income and expenditure of the three years ending the same date, and the number of interments per annum; from these figures the average deficiency, if any, for the three years in question could be obtained, as well as the average cost and loss per interment throughout the period. Information was also sought as to the estimated life of any cemetery or cemeteries now in use, and as to any authorised or contemplated expenditure on additional cemetery undertakings. All who have ever sent out a questionaire desiring detailed information will recognise that to receive 166 categorical responses in reply to under 200 requests is an unusual event: in this case it has no doubt been determined by the fact that the undertakings in question show an aggregate public loss in money, evidencing thus a position for which the municipalities themselves may welcome publicity, as they would welcome any practical measures of relief.

The returns have now been examined, checked, and tabulated by Mr. A. E. PIGGOTT, accountant and auditor of Manchester, and they form the most complete information of the kind which has been presented to the public, who have hitherto had to rely upon such references as could be discovered in the Municipal Year Books, the London County Council statistics, and the Ministry of Health statistics. The figures relate to 305 cemeteries owned and managed by local authorities, acting as burial authorities in their respective areas. The returns of the 166 municipalities have a reference to a total population of over 17,500,000, and the cemeteries occupy 8400 acres of land. An exact summary of the returns shows the following results:—

Capital expenditure on undertakings ..		£5,449,472
Total number of interments to March 31st, 1926		10,784,989
Expenditure per annum	(average of three years)	£800,405
Income ,,		£638,272
Deficiency ,,		£162,133
Number of interments per annum ..		173,073
Average loss per interment		£0 18 9
Average cost ,, ...		£4 12 6

The perusal of the returns, in which about one-half of the total population of England and Wales is represented, prove our methods of burial to be seriously extravagant, while the annual loss indicated may be increased, though it can hardly be diminished. A closer analysis of the figures points to an average gain of 11*s.* 5*d.* per interment in the case of 28 authorities only, while in the remaining 138 cases the average loss is £1 6*s.* There may be room here for economy, and the idea gains support from the considerable variation in the loss per interment in the different centres, which is heavier in the thickly-populated manufacturing towns. The explanation may well be that in some instances the expenses incurred have been on a pre-war basis, while in others they have been subjected to a post-war increase. But even if economy is possible in some, and possibly in many, areas, the fact will still remain that the land, whose present occupation entails these expenses in employment and upkeep is sterile, that this sterility occurs in the very places where the areas are most required for housing purposes, and that much land will have to be acquired annually for this unremunerative use. On all sides we can see chances of greater expense to the public, and on no side can relief be clearly expected.

It is nearly 25 years since the Home Office made its first regulations for England and Wales, subse-

quently replaced by those of 1920. It seems strange that similar regulations for Scotland are only now appearing. It has been calculated that, with a death-rate of 500,000 per annum, an area of 500 acres must be set aside yearly if earth burial is the method of disposing of the dead. Such a figure indicates to burial authorities that cremation has economic, as well as hygienic, advantages, yet cremation is but slowly overcoming the naturally conservative feelings of the community. As THE LANCET has remarked before, the only serious argument against the burning of the dead is the supposed danger that it may destroy the evidence of foul play. We find that danger slight. Before the Cremation Act was passed in 1902 cases were known in which persons had resorted to burning as a means of preventing an inquest. Since the Cremation Act has been passed and the burning of bodies has been meticulously regulated, it has never been suggested that cremation has been used for the concealment of crime. Murderers like CRIPPEN and ARMSTRONG, whose guilt was established by evidence from the bodies of their victims, might have saved their necks if the bodies had been burnt and exhumation thus made impossible; but they knew better than to run the risk of the medical supervision and examination which the Act enjoins.

In 1926, when Parliament wisely tightened up our system of death certification in the interests of public safety, it was the danger of concealing crime by earth burial rather than by cremation which required attention. The Cremation Regulations for England were made more stringent last year, and it is hard to see what more effective safeguards against foul play could be devised.[3] To summarise them once more, cremation can take place only at a recognised crematorium. Except where an inquest has been held and a coroner's certificate given, no cremation is allowed until the death of the deceased has been duly registered or a certificate has been given in pursuance of Section 2 (2) of the Act of 1926, that the death of the deceased is not required by law to be registered in England. Cremation cannot take place without the following formalities: First, there must be an application on Form A, with statutory declaration by an executor or by the nearest surviving relative; if anyone else makes the application he must show good reason why he does so, and why the executor or nearest relative does not. Then there must be a certificate on Form B, by the registered medical practitioner who attended the deceased in his last illness and who can certify definitely as to the cause of death, and a confirmatory certificate on Form C by another medical practitioner possessing specially prescribed qualifications. Forms B and C are not dispensed with unless there has been either an inquest or a special post-mortem examination by an expert pathologist. The statutory functions of the medical referee are particularly important. He must refuse to permit cremation unless satisfied that the fact and cause of death have been definitely ascertained; "and, in particular, if the cause of death assigned in the medical certificate be such as, regard being had to all the circumstances, might be due to poison, to violence, to any illegal operation, or to privation or neglect, he shall require a post-mortem examination to be held, and, if that fails to reveal the cause of death, shall decline to allow the cremation unless an inquest be held and a certificate given by the coroner in Form E." If it appears that death was due to poison or the other above-mentioned causes, "or if there is any suspicious circumstance whatsoever," the medical referee must decline to allow the cremation unless an inquest is held. Finally, he is not obliged to state any reason if he disallows cremation. It is hard to imagine more stringent regulations. In the working of them the country has placed remarkable confidence in the medical profession, and it is for that profession to ensure their successful operation and to remove any trace of popular misapprehension.

Annotations.

"Ne quid nimis."

HEALTH OF THE NAVY IN 1925.

THE latest annual report[1] of the health of th Navy deals with the year 1925. It appears nin months after its predecessor.[2] Its figures show few sick, fewer deaths, and fewer sick daily, though mo invaliding. Venereal disease is reduced, but tuberc losis has increased, especially at the higher ages. 1925 the average number of men in the "tot force" was 89,950, a slight increase. In additio there were also 4060 marines at headquarters, add tional to the "total force" mentioned. This group marines probably contains older men; they ha numerous small injuries, and more invalids from hea disease. They are remarkably free from venere disease, reporting no new case of syphilitic infecti and a total incidence of only 19 per 1000. T following comparative review shows the figures of t previous year in parentheses. The decimals are rat per 1000. The total cases amounted to 464·8 (486·2 of which wounds in action were 0·03 (0·04) and oth injuries 87·4 (90·0); the cases of venereal disea were 71·7 (81·8), and of all other diseases 305 (314·0). There were 254 (271) deaths, which ga a mortality of 2·82 (3·1). The chief causes of dea were: effects of suffocation, 73 (69 in the loss Submarine M.1); from tuberculosis, 37 (24); fro accidents, 28; pneumonia, 14 (13); heart disease 9 (6); septic infection, 8 (4); disease of intestin 7 (21); malignant disease, 7 (9); and enteric fev 3 (10). The chief causes of the 1412 (1272) invaliding 15·7 (14·5) per 1000, were: diseases of the ey mostly errors of refraction, 256 (161); tuberculos 224 (159); nervous diseases, 176 (191); diseases the ear, 144 (108); circulatory system diseas 99 (80); diseases of the digestive system, 80 (57 venereal disease, 77 (239); including gonorrhœa, (206); and injuries, 58 (60). The death-rate fro disease was 1·36 (1·78), the lowest hitherto record Vaccinations and revaccinations, 21,558 (15,868), noted; there were 2 (2) cases of small-pox. enteric fever there were 40 (85) cases with 3 deaths. A small group of 17 or 18 cases (no deat occurred in *Emperor of India* in the Mediterranea ascribed to "infected food, probably supplied fro the canteen"; the cases were all mild, which thought to be due to the recent preventive inoculati of all the patients (within 5–9 months). The figu of tuberculosis were unfavourable last year, and t year there is a considerable increase: cases, 2 (2·2); invalided, 2·49 (1·8); deaths, 0·4 (0·2 From the table on pp. 16–17 we gather that t increase in invaliding is chiefly at ages over 25, a in men of over five years' service, rather late for t development of tuberculosis that was present l latent at entry. Do these cases occur more in la or small ships? No explanation of the increase s offered in the report. The heaviest incidence see still to be on telegraphists, 12 (11). Non-pulmon cases are this year for the first time separated fr the others, and seem to prevail more at the earl ages. Pneumonia, 221 (182); deaths, 14 (13), l slightly increased, but pleurisy, 140 (160), is less, a there is less malaria, 258 (338), and less sandf fever, 65 (79), though more dengue, 43 (18). T incidence of venereal disease is less, 71·7 (81· China manifests its old baneful pre-eminence w 211·3 (248·4) cases, new cases 168·0; marine he quarters have an incidence of 19·19. There is n increase in cases of gastric, 71 (33), and duoden 52 (47), ulcers. There were no cases of scurvy repor this year, but 3 (2) of beri-beri. Scabies is a lit increased, 11·1 (9·56); each case averages 5·71 d

[2] THE LANCET, 1927, i., 1045.

ıder treatment. The account of the training ships meagre; they seem to have had 5 cases of tubercle ıd some 35 of pneumonia, but there is no account all of the health of the cadets at Dartmouth.

ANEURYSMAL DILATATION OF THE LEFT AURICLE.

In chronic rheumatic carditis, especially when itral stenosis is the main lesion, the left auricle ıdergoes a certain amount of dilatation and hyper-ophy. The extent of this dilatation is, as a rule, ırprisingly small in proportion to the work which ıs to be done. In rare cases, however, the auricle ecomes extremely dilated, and at autopsy its capacity sometimes found to be nearly 2 litres. The reason hy this excessive or aneurysmal dilatation occurs some cases and not in others gives rise to con-derable speculation, and is discussed in detail in ıe current number of the *Quarterly Journal of Medicine* by Dr. J. Crighton Bramwell and Dr. J. B. uguid, who report two cases which came under eir notice and review 18 others collected from the erature. They found that the associated adhesive ericarditis and lesions of the mitral valve varied so uch that neither could be regarded as the primary use of the extreme dilatation of the left auricle. ıe common lesion found was a localised ischæmic rosis of the auricular wall, and this, it is suggested, as due to embolic plugging of some abnormally tuated auricular branches of the coronary artery. still rarer cases weakening of the auricular wall is ıe to extension of disease from some neighbouring gan. The dilatation takes place in an unusual rection—the "horizontal dilatation" of some riters. In most of the cases the dilated left auricle as found to have extended under the right auricle ıd the superior vena cava to form the right border the heart, and in an extreme case such extension used collapse of the lower lobe of the right lung. om this it might be deduced that the abnormal stribution of the auricular branches of the coronary tery affects mainly the right side of the left auricle, ıd that the axis of the intra-auricular pressure is clined towards the right. It was often noticed at the exercise-tolerance remained good for many ars because, as Dr. Bramwell and Dr. Duguid int out, the brunt of the lesion falls on the auricle, hilst the ventricle remains healthy and able to pertrophy and maintain the circulation.

THE ACTION OF LIGHT ON THE EYE.

Some weeks ago we gave a brief account [1] of the ork of E. D. Adrian and Rachel Matthews on the scharge of impulses of the optic nerve of the conger l when the eye is exposed to light. These investi-ıtors have continued their researches, and in a further ıper [2] describe more particularly the initial stages of ıe process and the effect of flashes of light of short ıration—i.e., they deal mainly with the processes volved in the excitation of the retinal elements and ıt little with the subsequent nervous changes. The ethods employed were much the same as those used the previous work. Special attention was given to termining the reaction time—the period between ıe beginning of the exposures to light and the ginning of the response in the retina or nerve—ıd to the effect of intensity and duration of the ısh of light on the nerve reaction time. It was und that for a given intensity of light, flashes hich exceed a certain critical duration all give ıe same reaction time and a discharge of the same aximal impulse-frequency in the optic nerve. With ıorter durations the reaction time is longer and the ıpulse-frequency is smaller. Using flashes somewhat ıorter than the critical duration, it was found that definite quantity of light (intensity × duration) over a given area always produces a definite reaction time and a response of definite impulse-frequency, whatever the intensity of the light. These results hold good not only for changes in the intensity and duration of the flash, but also for changes in the area illuminated. A definite quantity of light (intensity × duration × area) produces the same reaction time, though the retinal area illuminated varies from 0·08 to 0·9 mm. diameter. The processes leading to excitation may be divided into a primary change, coinciding with the flash and forming a product proportional to the quantity of light received, and a secondary change outlasting the flash and leading ultimately to the excitation of the nervous structures. The rate of the secondary change is a linear function of the amount of "light product" or "light effect" found in the primary change. The relation between area and intensity must mean that the total effect of the light is transmitted to some region whose extent is independent of the area illuminated. The effect might be diffused widely over the retina or concentrated on a small number of nervous paths which have an overlapping distribution on the retinal surface. In either case, the transmission of the light effect must take place rapidly as part of the primary change, and the secondary change must occur in the region to which the light effect is transmitted.

We understand that Dr. Adrian will summarise his important observations in a book, entitled "The Basis of Sensation: the Action of the Sense-Organs," [3] which is now in the press.

LIFE INSURANCE IN THE TROPICS.

The interest of life insurance in the tropics to medical men lies chiefly in its property as a definite quantitative assessment of the extra risks to the life and health of a person who lives and works under climatic conditions to which he is racially unadapted. Apart from the especial responsibility of those who examine candidates for insurance, the subject is vital to all medical men practising in hot countries. The peculiar position of Britain as the administrator of large areas of the tropics gives it perennial importance, but it has been raised rather more acutely of recent years by the "white Australia" policy. Considering the money and lives involved, the certain knowledge which exists about these extra risks is surprisingly scanty, and the consciousness of this deficiency provoked an interesting discussion at a meeting of the Section of Tropical Diseases of the Royal Society of Medicine on Feb. 2nd. As Dr. J. F. C. Haslam pointed out in his opening paper, the health administrators of the Commonwealth are claiming that the increased risks are due solely to tropical disease, which in the absence of a native population is practically unknown in Northern Australia, and that a hot climate of itself is no menace to health. The difficulty is to get evidence. Dr. Haslam quoted Sundstroem, whose material was too small to give force to his results, and read part of a letter recently published by Sir James Barrett, [4] who considers that the matter has been settled by several generations of successful colonists. Sir Leonard Rogers, in the subsequent discussion, produced post-mortem figures showing that one-third of the mortality in India is due to tropical disease. Even if the Australian authorities are right, however, the variation between tropical countries is so great that their conclusion would be of little help elsewhere. Moreover, individuals and races vary tremendously, and southern Europeans may be expected to tolerate conditions which northerners might find impossible, in spite of the vehement assertions of Cilento to the contrary. A perusal of the very able Review of Literature on the Physiological Effects of Abnormal Temperatures and Humidities, published by the U.S.A. Public Health Department last year, will not, as Dr. Haslam

[1] The Lancet, 1927, ii., 1247.
[2] Journal of Physiology, 1927, lxiv., 279.

[3] To be published shortly by Messrs. Christophers, 22, Berners-street, London, W.1.
[4] Brit. Med. Jour., 1927, ii., 1244.

asserted, by any means convince a person of open mind that high temperatures have no ill-effect. Moreover, it is a matter of common consent that white women suffer more in the tropics than white men, and industrial experiments have shown that the adverse factors are actually the heat and humidity.

It is not, of course, true that insurance premiums are an exact measure of health risks, for their assessment depends to a large extent on the business policy of the particular company. The extraordinary variation between the rates for tropical insurance quoted by different concerns is, however, largely due to the failure of their medical advisers to provide them with adequate statistics. Dr. Haslam produced some figures supplied him by different companies for extra premium on a £1000 policy, payable after 20 years' residence in various parts of the tropics. The quotations for America varied between £25 and £150, those for East Africa between £20 and £180, and those for West Africa between £45 and £375. He stated, however, that fresh knowledge of the variations between different parts of the same colony is being used to modify the rates charged, and urged a much fuller study of the factors affecting health all over the tropics. From the actuarial point of view, a paper contributed by Mr. L. E. Raynes, of the Institute of Actuaries, corroborated the strictures passed by Dr. Haslam. The insurance expert uses the mortality table as his instrument, and this, as he reminded the audience, is valueless unless it includes a distribution of both the population and the deaths according to age. Offices have come to rely upon their own very limited experience of tropical mortality, and since much of this is necessarily spread over a great number of years, it cannot take account of the amelioration of conditions which has modified the actual mortality figures of most colonies during recent times. The results of Mr. Raynes's recent personal research provide evidence both for the importance of climate and for that of the presence of disease. He finds, for instance, that mortality is definitely lower in the hot dry plains than in the moist equatorial swamps, but also that the health and self-control of the Northern European, and his insistence on public hygiene, have a definite effect upon the death-rate. Moreover, he detects what may be a psychological factor in the returns of Northern Nigeria, where farmers live long but lonely pioneers fare badly. Lastly, he attaches importance to the disputed factor of acclimatisation. The general death-rate in the first 18 months of tropical residence is, he says, 1·405 per annum, but between 1½ and 4½ years it falls to 0·881 per annum, and some offices recognise this fact by lowering their rates after the first few years. This matter of acclimatisation was one upon which a good many speakers at this meeting held strong views. Dr. Andrew Balfour, the president, agreed with Cuvier that the nervous system was " at the bottom of the whole animal," and was what really got acclimatised. Dr. H. S. Stannus complained that the conditions in some colonies were now so favourable that men were protected from ever getting acclimatised. Dr. J. B. Christopherson thought that the blood was as important a factor as the nervous system, both in acclimatisation and in the ravages of climate. It was this speaker who raised a point which deserves consideration by every resident in the tropics: tropical conditions are hostile to health, but not to longevity; therefore the best form of insurance is the endowment policy. That this suits the insurance company equally well was admitted by Mr. R. E. Underwood, who likened it to a bet laid both ways. From the company's point of view, he said, it is a great advantage to get rid of a man before his time comes to die. Some companies offer a double endowment at ordinary rates to men living under certain types of mortality risks. Other important factors brought out in the discussion were occupation and personal habits. It obviously makes a great difference, as Mr. Underwood pointed out, whether a man is going lion-hunting or proposes to manage a bank, and at least one concern looks at the occupati more closely than at the man. Personal habi especially indulgence in alcohol, have much improv in recent years, but the question of how a particul candidate is likely to shape in this respect is st according to Dr. Graham Forbes, one of the unkno factors with which insurance companies have contend. The question is beset with innumeral difficulties, and is only to be solved, as Dr. Hasla said, by an enormous amount of patient work in parts, not only of the tropics but of countries wi similar climatic conditions, and in different distric of the same country. One factor in the statisticia favour is that the men who go out to these countr as servants of the Government or large tradi corporations are usually fairly sound to start wit. On the vexed heat and humidity question, Dr. Hasla quoted Dr. Leonard Hill's dictum that the importa thing was the rate of loss of heat. It is possible th extended work with the kata-thermometer m modify quite a number of current ideas.

THE YOUNG FILM-ACTOR.

REGULATIONS to protect juvenile cinema act are recommended on the ground that lazy or ambitic parents, fired by the rumour of fabulous incom are apt to push their children into the professi without regard for health and education. The c ditions under which these children work in parts f America has been impressively described by Ms Minor, of Toronto,[1] who speaks of long hours sp t in rain or snow; of excessive fatigue due to lc intervals between the filmings, during which there s no provision for rest or refreshment, of the effect f intense light on immature eyes, of the results f occupying childhood with simulated emotions a unreal personalities, and the methods in use p procure laughter or tears at the right moment fr tiny children. In some countries there is still p legislation to prevent these abuses, and in others e laws are rudimentary. Germany, California, and N York State, says Prof. G. Ichok in a recent artic[2] have special regulations governing employment, a these are, of course, the countries where the fi industry is most flourishing. Austrian and Ital n law forbids the use of children altogether, except r artistic or scientific films. In Berlin no child less th 3 years old may " act " for the cinema; but elsewh e no minimal age is enacted. Permission is requi d for children under 14 in Austria and Germany, un r 15 in Italy, and under 16 in California and New Yo. In Germany the children can only be employed r six hours a day, and no permit is granted unles a guarantee is given that the work will not affect e child's health. The same guarantee is required n Italy. In California the maximal working day s eight hours, four of which must be occupied in sch l instruction, which is provided in special classes n r the studio. In Germany the children must conti e their attendance at an ordinary school and perm s are refused if there is reason to think that the sce s in which the child is to appear are likely to have a ld moral effect or over-excite him. In Berlin, as in C i- fornia, a parent or member of the family must acco- pany the child, and between filmings he must be un r qualified guardianship. In Italy the authori s require the written consent of a parent or guard n and must be satisfied that the child will work i a good moral atmosphere. Th is in many countr s, Prof. Ichok shows, the entry of children into e cinema world is safeguarded, but once in it they e left more or less to their fate, except in Germa y, where the authorities demand precise information s to the scenes in which the children appear, the v y in which they are called to their work, and the clot s they wear therein. Berlin also prescribes a maxi al period of ten minutes for light and a special la p system.

[1] Revue Internationale du Travail, 1927, xv., 264.
[2] Revue Internationale de l'Enfant, 1927, iv., 755

Our own country differs in its methods. Although e theatre and similar institutions are covered by vs regulating the employment of children, the film dustry is not included. Local authorities, however, ve the right, under the Education Act of 1921, to bid or to regulate the employment of children in y industry. The general laws governing the work children ensure that no child under 12 shall work ve for his or her parents, and that no child under 14 ay work before 6 in the morning, after 8 in the ening, or more than two hours on a Sunday. In actice, Prof. Ichok thinks, the results are satisctory, as all local authorities have exercised the wers accorded to them, so that adequate restraint exercised without precise legislation such as is nd in America.

POST-OPERATIVE PNEUMONIA.

THE term "post-operative pneumonia" is loosely plied to conditions ranging from mild bronchitis to vere broncho-pneumonia and massive collapse of e lung. Even the dividing line that separates it m infarction is far from clear, for some authorities ld that pulmonary sepsis following operation is en embolic in origin.

In a recent review [1] Dr. Quénu and Dr. Oberlin scribe the main clinical types of post-operative mplications in the thorax. The commonest is nign; after an interval of from 24 hours to five ys there is a sudden rise of temperature, which soon ls again by lysis. In this type the physical signs e usually an area of dullness, with tubular breathing the base of the lungs; the sputum is mucopurulent d rarely tinged with blood, and the organism is often pneumococcus of type IV. Recovery is the rule, t worse symptoms may supervene. Alternatively e graver forms of infection may first manifest themves by fever on the third or fourth day, with signs broncho-pneumonia, and expectoration which is en fœtid. The course taken by the disease is riable and prognosis must be governed more by other ctors—hæmorrhage, infection, cachexia, age—than physical signs. Massive collapse of large areas of e lung has been described, especially after operations the upper abdomen. Here again the symptoms d signs are very variable and depend on the nount of collapse and the degree of obstruction of e bronchi, the sign of most diagnostic value being splacement of the apex-beat towards the affected le. Unless the collapse is gross the outlook should favourable.

Whilst mental and physical depression are important edisposing causes of post-operative pneumonia, e liability to contract it is also increased by the esence of infection in the nose, mouth, larynx, or onchi, or by previous damage to the lungs by eumonia or tuberculosis. Exposure to cold is other factor in causation, and the incidence is said be greater during the winter months. Irritation d cooling by the anæsthetic has also been blamed the ground that ether chills the alveolar air, ritates the bronchial tubes and alveolar epithelium, d causes a profuse secretion of mucus which forms ideal culture-medium for pathogenic organisms haled from the mouth and upper air passages. By ministration of warmed ether by the intratracheal ethod, it is claimed that these disadvantages can be ssened, but Dr. Quénu and Dr. Oberlin strongly commend that this anæsthetic should not be given the closed method in high concentration as the sult is often hypersecretion of mucus. Chloroform, though less irritant and less chilling, is more pressing to the patient, besides carrying the risk of dden heart failure, and therefore has no advantage er ether even from the point of view of post-operative fection of the lungs. Probably the rôle of the neral anæsthetic as a predisposing factor is considerbly exaggerated, for pulmonary complications are common after operations under local anæsthesia. What may be most important is the fall in blood pressure which usually follows a surgical operation, together with deficiency in aeration of the blood. This deficiency is especially noticeable after operations on the upper abdomen which make respiratory movements difficult, owing to pain and bandaging of the lower ribs. Distension of the stomach and intestines with gas and prolonged lying on the back cause further limitation and encourage retention of secretions in the lungs and bronchi. Whatever anæsthetic is used the most important factor determining post-operative pulmonary complications is the site of the operation. Upper abdominal operations are the common precursors and reflex inhibition of the diaphragm the immediate cause of the trouble.

PHYSIOLOGY IN POLITICS.

A VOLUME, entitled "Britain's Industrial Future,"[1] has just been issued under the authority of a number of highly competent men. The political leanings and claims of this report are obvious, but the stimulus given to thought and action by the comprehensive survey it presents must not be ignored by the medical profession for this reason. Rather the reverse; for when the laymen pay lip service in such maxims as "A nation's wealth is that nation's health," the truth obtains confirmation from medical work. Unrest and deep-seated discontent are expressions in the body politic, as in the individual, of irritation and underlying pathological trouble. Nevertheless, if anyone is too riddled with disease, like a race ridden by malaria, he has not the energy to express discontent—that divine spark of convalescence. History has portrayed this spark breaking forth ever and again into flame as the political ill-health of mediæval Europe culminated in the feverish forms of revolution; the industrial strikes, which are symptomatic of modern unrest are similarly signs of a sickness among nations who are now convalescing. The different pathological combinations of governance and public health, which spell either revolution, or hardly won progress, or steady advance towards that full and free life which eager hearts expect, have never been determined. But every nation is said to possess the government it deserves; an unhealthy people can get little value from what, for a vigorous race, would prove a stimulating constitution, while a strong stock will find an apparently oppressive state barely a burden to be lightly tossed aside.

Such are the things which add significance to the analysis given early in this report of the present state of British national life and industry. The truth is admitted that the wealth of the country is at present ill-distributed; no word is added that the distribution of the nation's health is at least as diverse—a truth borne testimony to by the Registrar-General's occupational statistics, noticed in our columns last week. So long as the distribution of health is ill-adjusted, so long will the distribution of wealth be ill-adjusted, no matter what draught of reorganisation be administered to the body politic. Minimum wage schemes and family allowances must fail, so long as they are based on the "capacity of industry to pay," rather than on the physiological necessities of life; and we are happy to believe that those who have the conduct of our national business are now aware of all this. Certain necessities are fundamental, not merely to health and contentment, but to life itself. This was revealed in the war dramatically, but the lessons then learned remain pertinent to-day. We find in these pages that two trustworthy authorities have stated a coal-miner's daily need for food-energy to carry on his work at widely different figures. There this important question is left undecided, while from every side panaceas are propounded to cure the poor coal trade patient on the basis of what he can afford to pay. What, however, must the miner eat to enable

[1] Britain's Industrial Future. Being the Report of the Liberal Industrial Inquiry. Ernest Benn, Ltd. Pp. 503. 2s. 6d.

him to do so many foot-pounds of work underground? Many political economists fail to appreciate, or argue as if there were such failure, that calculations must give way before the laws of life, whereas they should be founded upon those laws. Dublin, the American medical statistician, has suggested forcibly that the real value of human life at any time amounts to five times that of property, while healthy life is of more value than unhealthy life. Public health has so greatly improved as to be deserving of an improved governance to match. Whether adoption of the comprehensive programme advocated in this report—and the programme has the merit of boldness in some fields, even though so neglectful of certain fundamentals—would meet the need, we do not presume to discuss. One advantage it possesses in strongly advocating development of the homeland, the place where the people live, by extended road construction, by more garden cities, by slum clearance on a large scale, by developing docks, harbours, canals, and electrical supply. Health, like wages, must be earned by work, and, in so far as this development would find work where to-day there exists unemployment, it would further improve the nation's health. The means to this end are set out well in this report which is long, but well written; it deals in sequence with the condition of industry, and the organisation of business, with industrial relations, national development, and finance; finally come 36 closely printed pages of summary of conclusions. For us the interest lies in the contribution made to furthering the economics of health. Health is largely a product of environment and food, and by health is meant both physical and mental vigour. Both environment and food-supply in the homeland can be improved. By the time England has been made a land fit for heroes to live in, a heroic race will be found inhabiting it, and indeed to have made the land fit for their habitation. Meanwhile it is—

> That unto him who works, and feels he works,
> This same grand year is ever at the doors.

CONVALESCENCE.

EVERYONE with experience of hospital practice will agree that, owing to the pressure of a long waiting-list, many patients must be discharged in an only partially cured condition. In England a fortunate minority do indeed obtain a few weeks at one of the convalescent homes attached to the larger hospitals, but of necessity the majority must return to their own homes, which, as a rule, cannot provide a suitable environment for convalescence. Some of these patients continue to attend as out-patients for tonics or dressings, but many take their final leave of the hospital still feeling far from strong and receive little or no further guidance and encouragement to help to restore sufficient vigour and self-confidence for a return to full work. In a new book on "Convalescence, Historical and Practical,"[1] Dr. John Bryant records the efforts that have been made in the past by different countries to remedy this defect and to prevent this class of patient drifting to chronic invalidism, a prey to charlatans, and a burden to the rates. London took the lead with the Metropolitan Convalescent Institution established in 1844, and was followed by Paris in 1857, when Napoleon III. decreed the foundation of special convalescent hospitals at Vincennes and Vesinet. America was slow to follow this example, and it was not till 1915 that the Burke Relief Foundation was established for New York and equipped with every facility for occupational therapy. Armed with a keen interest and wide experience of military and civilian practice in this type of work, Dr. Bryant writes with authority and a wealth of detail. Struck by the scantiness of the literature on the subject, he insists that the profession is absorbed in the laboratory viewpoint of medicine and in dealing with acu cases, and that it has neglected the care of the co valescent. Patients are left "half cured." Convale cence is as much a mental as a physical conditio and occupational therapy combined with prescrib graduated exercise is of as much importance as go food and country air. Arguments on the econom side are no less convincing. Convalescent homes a far less costly than hospitals to construct, and t cost of maintaining a patient in them is estimat at one-third of the cost of a hospital case. Agai with adequate convalescent accommodation to f back on, the average stay in hospital can be shorten and expensive hospital extensions may be avoid by a more rapid turnover of patients. Finally, t rates are relieved of the burden of a large number chronic invalids. The book consists of a series articles by Dr. Bryant, revised and incorporated a single volume. This construction leads to lack continuity of argument and some repetition, b the work is of real value in pointing the reme of a serious defect in our present hospital and pub health systems. The chapters describing the Bur Relief Foundation and the occupational thera employed in the U.S. military convalescent cam during the war are of particular interest. They sh what can be done given sufficient resources a enthusiasm, and should be read by all who a interested in the future of our hospital and pub health services.

THE CAUSES OF INTRA-UTERINE DEATH.

THE Medical Research Council published in 19 a clinical and pathological study, by Dr. Eardl Holland and Dr. Janet Lane-Claypon,[1] of 1673 de births and neonatal deaths. This summarised t combined investigations of many workers at differe centres throughout the country. In a further rep just issued[2] Mr. A. C. Palmer publishes a detai account of one of these investigations, dealing w 144 cases of fœtal death observed at the Lond Hospital; 141 of the patients were Whiteha women delivered in their own homes by stude or nurses from the hospital; three were priv patients of members of the staff. A complete necrop including weights and measurements, was perfor on all the infants, and the placenta, when obtain was weighed, measured, and examined macroscopica and microscopically. Most of the sections were p pared according to Levaditi's method and investiga for syphilis; other specimens were stained w Ehrlich's hæmatoxylin and eosin, with Weige iron hæmatoxylin and van Gieson's mixture or w Weigert's fuchselin and lithium carmine. Oth were examined fresh on dark-ground illuminati Eardley Holland's first investigation, published 1922, showed that about 20 per cent. of stillbo fœtuses are macerated. Of this series 39, or 27 cent., were macerated and 35·9 per cent. of th were proved to be syphilitic by the identification the *Spironema pallidum* in their tissues. Toxæmia pregnancy, indicated by albuminuria in the moth probably accounted for the death of 11, 7·6 per ce of the total or 28·2 per cent. of the macerated. T cause of death in 12 more was obscure, but mater albuminuria could only be certainly excluded in of these. Maternal morbus cordis and fœtal m formation each accounted for one death. Asphy accounted for the death of 91 out of the 99 m macerated fœtuses, in 12 of whom intracra hæmorrhage from excessive moulding appeared be the fatal factor. Of the eight cases showing asphyxia three had fœtal anasarca and the others died from conditions, such as hydrocephalus eclampsia, which would have caused asphyxia the child lived long enough. Of the six infants w breathed for a short time after delivery, four asphyxia and one had intracranial hæmorrha

[1] Special Report Series No. 109. London: H.M. Statio Office. 1926. 3*s.* 6*d.*
[2] Ibid., No. 118. 1928. 3*s.*

f all the 105 non-macerated fœtuses, 27 died as a sult of maternal disease and 5 of fœtal disease or alformation. Labour accounted for the death of 3, or just under 70 per cent.; syphilis for less than per cent. The placenta revealed no signs of maternal fœtal disease in any of the 99 cases in which it was xamined.

This report emphasises once more the findings of the rger series. With a few exceptions a dead baby is ie result of one of three things: difficulty in labour 0 per cent. of this series), maternal disease (18·7 per nt.), or syphilis (11·3 per cent.). All these are eventable conditions, and adequate antenatal care ould have removed or foreseen the threat to the ild's life. It also appears that syphilis is unlikely have caused the death of a non-macerated fœtus.

MOTOR-CAR ACCIDENTS AND HOSPITALS.

FOR some years past the pressure upon hospital eds and hospital finances caused by the rapid crease in the number of motor-car accidents has been owing in severity. The enormous annual output of otor vehicles of all kinds from the formidable trolley id hardly less formidable charabancs to the deadly otor-cycle, which must move the jealousy of Jehu the shades, forbids the hope that the pressure has eached its peak, and we may therefore confidently xpect that the difficulty will become still more acute. ll over the country hospitals, large and small, are nbarrassed by the necessity of admitting casualties o already overcrowded wards and by the cost of eating patients who are often so seriously injured that eir tenure of beds, sorely needed for local purposes, is rolonged. Thus the annual report of the Manchester Royal Infirmary, which has just been ssued, records the admission of a daily average of 0 casualties—one every 18 minutes throughout the 4 hours. Most general hospitals can tell much the ame story in proportion to their size and geographical tuation. In the hope of obtaining precise informaon on the subject Mr. H. W. Burleigh, the chairman f the Hospitals Motor Accident Policy Association, ast autumn addressed a letter to us asking for details f motor accidents treated at hospitals throughout the ountry. His invitation has been responded to by 183 ospitals, representing 14,169 beds—about one-third f the total of available beds—and the information e has obtained satisfies him that, irrespective of fees o medical men, the cost of motor accidents to the ospitals in the mass must be about half a million a ear. That is an alarming figure, but, as we have said, he trouble does not end there. Lack of pecuniary lasticity is accompanied by inelasticity of beds, and Ir. Burleigh is informed that in many small hospitals, t the approach of the week-end, when the maiming s at its height, medical officers have to hasten the ischarge of the local patients for whom the institution rimarily exists, to be ready for injured motorists, ainly from a distance. To say that this is a grotesque tate of things is to put the situation mildly. This art of the difficulty will not be removed by any rrangement for payment by, or on behalf of, these asualty patients, but it would at least ease the ecuniary perplexities of the hospital and help, in ome measure, towards the provision of more extended ccommodation. It is, therefore, hopeful news that he Eagle Star and British Dominions Insurance ompany have devised a policy which, for a premium f 5s. a year, will guarantee to the hospital which treats patient, injured by a moving road vehicle, a payment f half a guinea a day up to 30 days, together with hree guineas for medical fees, or five guineas should he patient be detained for more than a week. For asualty patients treated, but not admitted, half a uinea would be paid to the hospital and a similar ee to the medical officer. The thoughtful and conderate motorist may reasonably be expected to avail imself of these facilities, especially as he may take ut a policy for each seat in his car—the careful driver s often the victim of the reckless one. It is suggested ith less reason that the pedestrian and the rider in omnibuses and taxi-cabs should do likewise, but it is obviously desirable that there should be as much insurance as possible. There is grim irony in the provision that half benefits only can be paid in respect of motor-cycles and sidecars, though the driver of these dangerous machines may equalise matters by taking two policies for each seat. Simultaneously with the creation of this interesting policy we learn that the Middlesbrough Motor Club has instituted an insurance scheme which, for a premium of half a crown a year secures payments to hospitals in any part of the country ranging from half a guinea for a dressing to £15 for a detention of five or six weeks. If the motor insurance companies would now recognise the indebtedness of their insurers to the hospitals the pecuniary side of the difficulty might be fairly met on large lines. That would surmount what is supposed to be the legal obstacle to voluntary hospitals levying a charge for the treatment of road casualties, and if it be the fact, as has been urged on behalf of these companies, that their premiums are too low to admit of payments to hospitals, it would merely seem that an essential element of protection is lacking. The low terms of the new policies to which we have referred suggest that a very small addition to their premiums would meet the difficulty. To safeguard a man against the injury or destruction of his car while he sponges upon hospitals and doctors for the cost of mending his body suggests a lack of appreciation of rather elementary ethics. Meanwhile it is announced that the King's Fund intends shortly to call a conference of representatives of the hospitals, the insurance companies, and the leading motorists' organisations to consider the whole subject.

Sir James Berry, consulting surgeon to the Royal Free Hospital, has retired from practice, but will remain on the Council of the Royal College of Surgeons of England and complete his term of office as President of the Royal Society of Medicine.

A SPECIAL meeting of the Charity Organisation Society will be held at 296, Vauxhall Bridge-road, S.W., on Feb. 13th, at 3.30 P.M., under the chairmanship of Lord Dawson of Penn, when Sir William Hamer, Dr. Graham Little, and Dr. Humphrey Nockolds will speak on the Voluntary Hospitals and the Public Authorities.

INDEX TO "THE LANCET," VOL. II., 1927.

THE Index and Title-page to Vol. II., 1927, which was completed with the issue of Dec. 31st, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

CONGRESSES IN CAIRO.—The centenary celebration of the Cairo Faculty of Medicine, combined with an international congress of Tropical Medicine and Hygiene, will be held from Dec. 15th–22nd. The centenary celebration will include sectional meetings in the different departments of the faculty, including operations and demonstrations, and the programme for the congress will include two general meetings on ankylostomiasis and bilharziasis. It is also proposed to arrange a medical exhibition of drugs and appliances. Further particulars may be had from the Secretary-General, Congress Bureau, Faculty of Medicine, Cairo.

The Journées Médicales d'Egypte will take place from Dec. 12th–23rd under the presidency of Prof. J. L. Faure. The subjects under discussion will include the diseases of both temperate and hot climates. There will also be an international exhibition of arts and science as applied to medicine, surgery, pharmacy, and sanitary hygiene. Further particulars may be had from the general secretary, 32, rue Gay-Lussac, Paris V^e. At both the congresses the official languages will be French, English, Arabic, German, and Italian, and members will be granted reduced fares and facilities for travel.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXII.

THE TREATMENT OF PLEURISY.

THE frequency with which pleural adhesions are found during routine post-mortem examinations suggests that pleurisy is far from being an uncommon disease. Attacks of pain in the chest or shoulder are often due to pleurisy although they may not seriously affect the general health, and are considered by the patient to be the result of muscular rheumatism, growing pains, or indigestion.

In the great majority of cases pleurisy is due to the tubercle bacillus and it is better to consider the disease under two headings, non-tuberculous and tuberculous. First, however, I will discuss briefly a few general principles of treatment.

Principles of Treatment.

1. *General Treatment.*—During the acute stage when the patient is febrile he should be kept in bed in a warm but well-ventilated room. The diet should be light but must depend on the state of the patient's digestion. If the tongue is clean and the digestion good a generous diet should be given, but if the patient has nausea and cannot digest food it is best to rest the stomach and give a very light diet until the desire for food returns. The bowels should be regulated, and it is wise to give a dose of calomel at the onset of the illness.

2. *Pain* can usually be relieved by strapping the affected side. The strips of strapping should pass from the vertebral column completely round the chest to beyond the sternum. They should be applied and drawn tight when the chest is in a state of expiration, and it is important to see that they are fixed evenly on the chest. This restricts the movements of the affected side of the chest and relieves pain, but it is not necessary to strap the chest unless there is severe pain.

Where there is very little pain or only a dull ache the application of antiphlogistine or thermogene wool is quite sufficient to relieve the pain, and the feeling of warmth produced is very comforting to many patients. Aspirin or a mixture containing pyramidon and bromide will relieve the continuous aching pain of which some patients complain. If the pain is very severe a small quantity of air or oxygen should be introduced into the pleural cavity to separate the parietal and visceral layers of pleura; 200 c.cm. is usually sufficient to do this, and not only does it give immediate relief, but when the two pleural surfaces again come into contact the pain does not return, possibly because a layer of lymph forms over the inflamed surfaces. It is not therefore necessary to repeat the injection of the gas.

3. *Cough* is generally dry and useless, and if troublesome should be controlled by a linctus such as: morph. acet., gr. $\frac{1}{16}$; acid. nit. hydrocy. dil., ℥ii.; glycerini, ʒss.; aq. ad ʒi. If this fails a linctus containing heroin should be substituted.

4. *Fever.*—The temperature usually falls by lysis in a few days. If it persists one may suspect either the formation of an effusion or a spread of tuberculosis. It is unwise to try to control the temperature by drugs.

5. *Sleeplessness* may be due to pain, dyspnœa from effusion, or cough, and the treatment is to deal with the cause. If, however, the patient cannot sleep, and there is no apparent cause, omnopon, gr. $\frac{1}{3}$, given by the mouth, soneryl, grs. $1\frac{1}{2}$, or medinal, grs. 7, will usually give the patient a good night, but drugs of this sort should be discontinued as soon as possible.

Non-tuberculous Pleurisy.

Pleurisy may be due to a variety of causes. It is not uncommon in the late stages of chronic diseases such as nephritis, and it often follows malignant disease of lung or adjacent organs. It may result from the spread of local inflammations such as pericarditis or pneumonia. In cases of pneumonia due to the pneumococcus there is always some pleurisy which usually heals as the pneumonia resolves. If, however, it leads to an effusion, the fluid formed is purulent and not clear, and we are not concerned with the treatment of empyema in this article.

Streptococcal pneumonia may cause a pleural effusion which is cloudy and opaque, like milk-and-water. These cases are very acute and often fatal, but it is better to aspirate than to resect a rib and drain the effusion. If the fluid re-forms after aspiration and the temperature remains high, the pleural cavity should be washed out with normal saline or a 1 per cent. solution of methylene-blue, and left as dry as possible. At the same time oxygen should be introduced into the pleural cavity to replace the fluid removed. The quantity of oxygen necessary must depend on the size of the effusion and the amount of fluid removed, but enough should be given to leave the intrapleural pressure between 0 and −5 cm. water. Good results are often obtained by these methods even in severe cases, but aspiration alone is usually quite sufficient in the milder cases.

When pleural effusion is due to nephritis or heart failure aspiration relieves the dyspnœa, and the removal of 15 or 20 ounces, especially in cardiac cases, will often make the patient much more comfortable. When the effusion is secondary to neoplasm it should be remembered that it will soon re-form after aspiration, and that there is no need to remove all fluid except to relieve pressure symptoms. In some conditions, such as endothelioma of pleura, the fluid forms very quickly so that it may be necessary to aspirate every day or even twice a day.

Tuberculous Pleurisy.

Patients suffering from pulmonary tuberculosis always have some pleural involvement and are liable to recurrent attacks of pleurisy. But pleurisy often occurs in patients previously regarded as healthy, and in whom there has never been a suspicion of tuberculosis. If we regard such cases as due to the tubercle bacillus which has reached the pleura through the lung it follows that the patient is in grave danger of developing pulmonary tuberculosis. It has been estimated that over 40 per cent. of patients with so-called dry idiopathic pleurisy subsequently develop pulmonary tuberculosis. Of course a large number of patients with tuberculous pleurisy do not develop the disease in the lungs, but completely recover or are left with nothing more than some adherent pleura. There is, however, no doubt that the very great majority of cases of pleurisy are due to the tubercle bacillus, and treatment must therefore be directed to preventing the development of pulmonary tuberculosis as well as to curing the pleurisy. It is often said that tuberculosis of lung is one of the most curable of diseases if treated early enough. Here we have the disease in the earliest stage, and if later a definite and active lesion develops in the lung one cannot help feeling that it might have been prevented.

During the initial acute stage of pleurisy the patient should be put to bed and treated on the general lines already described; recovery is usually quick and uninterrupted.

Sometimes, however, a pleural effusion develops. The fluid is clear and straw-coloured; it contains few cells, most of them being lymphocytes; tubercle bacilli are not found at first, but they appear in effusions which have persisted for three or four months; no other organisms are found. With the formation of fluid the pain disappears and the patient usually feels much better in himself although the temperature persists.

As soon as an effusion has been diagnosed it is safest to remove 5 c.cm. of the fluid for examination in order to make certain that it is not an empyema. If the fluid is clear and appears to be of tuberculous origin it will usually become absorbed in the course

a week or two, and it is better to allow a natural sorption than to aspirate.

Aspiration should be performed only if the effusion is so large that it causes considerable dyspnœa or pressure symptoms, or if it is desired to convert the fusion into a pneumothorax. When more than ounces of fluid are removed it is always best to place it with air or oxygen, otherwise the sudden pansion is apt to set up an acute tuberculosis of the ng, and the rapid lowering of the intrapleural essure may cause œdema of lung, faintness, or even lden death. Oxygen should be given to replace e fluid if one wants the lung to expand in a day or but air is better if it is desired to maintain a eumothorax. This should only be done if the lung ows signs of active tuberculosis.

In some cases where the fluid has taken a long ne to absorb autoserotherapy has been performed. out 10 c.cm. of the fluid are drawn into a syringe, d the needle is removed from the pleural cavity, t before withdrawing it from the skin the fluid is ected into the subcutaneous tissues. I have seen advantage from this procedure, but it is true that e removal of a few c.cm. of fluid for examination is en followed by the rapid absorption of the effusion.

When the patient has recovered from the attack of pleurisy or effusion it is very important to restore his general health and guard against the development of pulmonary tuberculosis. The patient has the right to be told of his danger and will have a very real grievance if he is not told, although one does not want to alarm him unduly. He should be advised to go through a course of training, living regularly, and combining periods of rest with a graduated and gradually increasing amount of exercise. This treatment can be carried out in a sanatorium better than anywhere else, and in no type of case is the value of sanatorium treatment seen to greater advantage. Some patients dread the word sanatorium, and others consider the suggestion of going there a personal insult. In most cases, however, the patient is only too willing to do anything to avoid becoming consumptive, and if it is explained that sanatorium treatment is advised not because he has consumption, but to prevent him from developing it, he will usually agree to that or at any rate to some similar course of treatment.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT FOR 1926–27.

THE Report[1] of the Committee of the Privy Council Medical Research for the year 1926–27 contains uch interesting matter. The grant-in-aid of £135,000 ovided by Parliament has been allocated as llows: for administration £9000; to the National stitute for Medical Research, Hampstead, and the m laboratories, Mill Hill, £46,000; for research ants to scientific workers and for the Industrial tigue Research Board, £80,000. Additional grants ve been received for particular investigations from e Dental Board of the United Kingdom, the Empire arketing Board, the Miners' Welfare Fund, the itish Empire Cancer Campaign, and the "Field" stemper Research Council, as well as by private nefactions. The Committee point out that the ilities provided by universities and other centres of search are a valuable form of help. Sir Hugh nderson and Prof. T. R. Elliott have taken seats on e Council in place of Sir Frederick Andrewes and r Cuthbert Wallace, who retire in order.

The Medical Research Council publish their irteenth report this year. They have coöperated th the Ministry of Health, the Scottish Board of ealth, the Home Office, and the departments of ientific and Industrial Research. A Colonial Medical esearch Committee has been appointed to advise the cretary of State and the Council upon medical search in the colonies. The new machinery provided r the Committee of Civil Research is a simple, direct, d flexible method of securing discussion on problems fecting different parts of the Empire in the common ht of administration, experience, and scientific owledge. Steady progress has been made towards e linkage of the research organisations in Great itain with the equivalent organisations in the dian Empire and Dominions. New arrangements ve been made for bringing the Council's research rk into close and regular touch with that of the lonies, Protectorates, and mandated territories. whole-time scientific secretary has been appointed the two departments acting together. It is hoped at the new machinery will enable every part of the tal resources of the Council to find a useful place in e schemes of the new Committee. The Report ints out that tropical disease can no longer be regarded as a separate department of medical research. The stage is set for intensive laboratory investigation to follow up the preliminary field work which is now completed in most directions. In the first place it is being recognised more and more that errors of nutrition produce many diseases formerly called tropical. Secondly there are many non-tropical diseases, such as tuberculosis and measles, which are as common in the tropics as in England and which could in some ways be better studied abroad than at home. With every year it becomes increasingly clear that medical science is one and indivisible and that the work should be done wherever the man best fitted for it can most easily find his opportunities for progress.

Work on the Heart and Circulation.

The past year began a new decade of the work of Sir Thomas Lewis and his colleagues, and a review of the researches he has made for the Council is given in the Report with the comment: "It is not an exaggeration to say that the output of valuable work from this centre in the last decade has constituted the central stream of progress made in these subjects anywhere." The work is summarised in a recent monograph, "The Blood-vessels of the Human Skin and their Responses," and the results have immediate value for clinical medicine.

Cutaneous blood-vessels subjected to various forms of stimulation, or to histamine, contract imperfectly if at all, under the stimulus of adrenalin and pituitary extract. Telangiectases react in the same way and to this their dilated state may be attributed. The intensity and distribution of emotional blushes is also affected by differences in the tone of the minute vessels. The reaction of skin to ultra-violet light resembles that effected by other forms of stimulation in that it is attributed to the release of a histamine-like substance in the skin. Evidence has been brought to show that the anaphylactic poison in a "fish-sensitive" subject acts on the vessels of the skin by liberating a histamine-like substance. Weakness of the blood-vessel wall has been shown to be an important factor in causing cutaneous hæmorrhage in various diseases. Vessels which have been exposed to injury, such as ultra-violet light or freezing, show a lowered breaking strain. The distribution of hæmorrhages in the skin is governed largely by the pressure obtaining in the corresponding minute vessels and by the local condition of the vessel wall. Drs. Wetzel and Zottermann have confirmed the opinion of previous workers that the coloration of the skin in different parts and different people is chiefly determined by the minute veins, and by size rather than by number. The differences in size are due to differences in the responses which the vessels can offer to distension. A long series of observations shows that the vascular response to injury is always independent of nerves and the flare surrounding the point of injury is brought about by axon-reflex through local sensory nerve-fibres. Vaso-dilatation has been shown to be due to the release of a histamine-like substance in the skin when a sensory nerve-fibre is cut. Sir Thomas Lewis and

Dr. H. M. Marvin suggest that herpes zoster is produced in this way, that antidromic impulses are concerned in controlling the metabolic or secretory activities of tissues supplied by them, and the trophic lesions are due to disturbances of this control.

Dr. A. N. Drury and Dr. N. W. Jones have investigated the rate of dropsy formation and described a method of measurement and the effects of different venous pressures and temperatures. Dr. R. T. Grant has published a description of the development of the coronary vessels of the heart, and has studied a case of defective pericardium, and concluded that the pericardium normally plays no part in supporting the heart wall. Dr. A. A. Osman has applied modern methods of biochemistry to the study of Bright's disease, and published results in the centenary year which give promise of adapting with more certainty of success the treatment of this disease to the particular disorder present. Dr. Osman's work, reported last year, on tests identifying those patients of scarlet fever who are likely to develop nephritis, has been confirmed upon a large scale. His method of treatment by alkalis is said to have reduced the incidence of renal complications from 5·5 per cent. to 0·6 per cent.—a very striking achievement.

Vitamins.

Dr. O. Rosenheim and Mr. T. A. Webster have succeeded in producing vitamin D by the action of ultra-violet light upon a sterol.[2] Recent work has abundantly confirmed their conclusion that ergosterol is an abundant, rapidly available, and astoundingly potent preparation of vitamin D. One ten-millionth of a gramme suffices to prevent rickets in a rat. A number of problems arising from this discovery are now being attacked. Ultra-violet radiation not only forms a vitamin from ergosterol, but destroys it when formed; effort is being made to select regions of the spectrum in which the formative outweighs the destructive action. Cholesterol from skin has been examined and found to contain the vitamin-yielding impurity. This seems to justify the assumption that the preventive and curative effects of sunlight on rickets are due to the natural production and absorption of vitamin D. We can now obtain abundant and cheap supplies of the antirachitic vitamin in a potent and isolated form, so that it is easy to examine the properties of vitamin D without the complications induced by the presence of vitamin A. So far there is no clear evidence of the chemical nature and affinities of the latter vitamin. The colour reaction introduced by Dr. Rosenheim and Prof. Drummond has been used to explore its distribution in the fats of different organs in many animals. The proportion present in some liver fats may far exceed that found in cod-liver oil. The liver oils of the salmon and halibut may be more than a hundred times as rich in vitamin A as cod-liver oil, as may also the liver fats of birds like the grouse or the goose. Dr. Rosenheim and Mr. Webster have found that the liver fats of the sheep, calf, and ox contain ten times as much vitamin A as cod-liver oil, and that the content in butter varies widely according to circumstances. Calculation has shown that the total supply of milk-fat throughout the world is inadequate for the minimal needs of the population. The crucial problem is not, therefore, the hopeless difficulty offered by the shortage of milk-fat; it is the problem of the supply of fat-soluble vitamins which, in the light of these discoveries, can now be cheerfully faced. Our national needs of vitamin A can be met by the addition to the diet of substance from liver fat, either in butter in or margarine or in other ways. It has already been found that the vitamin content of fat from imported New Zealand liver is the same as that from home-killed animals. Moreover the fats extracted from the liver are free from the unpleasant flavour of fish oils and their low melting-point greatly aids incorporation with other fatty materials. The problem of the supply of vitamin D is also now easily solved. The liver fats contain almost none of this vitamin; apparently herbivorous animals, unlike fish, do not store vitamin in the liver. Since, however, it can be produce artificially by irradiation of ergosterol there is no nee to search for natural products.

Human rickets can be very rapidly cured by daily dose of 2 mg. and the amount needed f preservation of health is therefore extremely sma Improvements in the mode of irradiation, alread foreseen, will make a practically unlimited supp available. There is no doubt that the great majori of the population are suffering from deficiency in the essential food elements, and the cost in huma suffering and economic loss is incalculable but certain vast. The Report points out the immense value the nation of nutritional studies, affecting as they a at a thousand points the food of the population, i choice, its preparation, and its manipulation in t kitchen. A small representative Nutrition Committ which was appointed last year drew up a comprehe sive and coördinated programme of work and a attempting to frame a chemico-geographical survey the inorganic constituents of diet available in differe parts of the country and their relation to the distrib tion of disorders in human and animal life. Anoth problem is the so-called "man value"; what are t factors to be rightly used in referring quantitati dietetic estimates of a safe man-power standard by d allowance for age and sex? There is reason to belie that the factors at present used undervalue t requirements of children, and that the standard f the average adult man is too high. What, again, s the biological value, if any, of food taken in exc of the actual needs of the body as judged by t energy expenditure? It is not yet scientifically know how much water a man should drink or what is t best kind of bread to eat. We cannot guess wh natural relations of diet to disease or liability disease are waiting to be revealed.

These are some of the problems which will be unc consideration during the next year of resear activity. The Nutrition Committee have unc consideration more comprehensive schemes for s veying the dietetic needs of different sections of t population and the deficiencies in diet that can traced to remediable accidents of soil, water-supp or the treatment and distribution of foods.

THE HUNTERIAN BICENTENARY.

ON Feb. 13th the bicentenary falls of John Hunte birth, and the occasion will be appropriately ce brated by the Royal College of Surgeons of Engla the guardians of the magnificent museum, in Lincol Inn Fields, which bears Hunter's name and has be developed from Hunter's remarkable collection.

The Hunterian Oration will be delivered by Holburt Waring at 4 P.M. on Feb. 14th, on Progress of Surgery from Hunter's Day to Ours. T Oration will be freely illustrated. The festival din is arranged for 8 P.M. on the same day. On Feb. 1 there will be a reception in the College from 3 to 5 P. and the Thomas Vicary Lecture on the Homes Hunter will be delivered by Dr. G. C. Peachey 5 P.M.; a special display of Hunterian specim has been arranged by Sir Arthur Keith, the C servator, and interesting Hunterian relics will shown by Mr. Plarr, the librarian of the Colle during the week.

Thus from Monday, Feb. 13th, to Feb. 18 except on the afternoon of Thursday, Feb. 16 visitors to the Royal College of Surgeons will h an opportunity of examining an extensive display Hunterian portraits, specimens, and relics. In conservator's room will be shown a series of portr representing John Hunter at succeeding times of l His manuscripts and drawings are to be placed exhibition. The conservator has selected specim from the general collection to illustrate the chief Hunter's discoveries. The University of Glasg the governors of St. George's Hospital, the Soci of Apothecaries, and representatives of the Hu

nily have made valuable contributions to the hibition. Specimens have been arranged to illus- ate the background of Reynold's picture of Hunter in some instances the actual specimens being shown. valuable collection of Hunterian relics has been tained on loan from the Wellcome Historical Medical iseum, by the courtesy of Mr. Wellcome.

Dr. Peachey, Vicary lecturer, at the request of the uncil of the College, has had prepared a series of otographs, sketches, and maps to illustrate the rious residences and schools occupied by the nter brothers in London, showing them as they re a century and a half ago and what is preserved them to-day.

New Hunteriana.

Among the many relics of John Hunter which will exhibited at the Royal College of Surgeons on the casion, assuredly one of the most interesting, cently acquired, is the bureau or desk, surmounted a bookcase, presented to the College in 1927 by iss Margaret Hunter. This is one of three bureaux, o of which are now the property of the College, e third being in Edinburgh. Of the College desks e is the escritoire with a roll-top, which has long en a familiar object to visitors to the institution. contains secret drawers and is erroneously supposed have been constructed by John Hunter himself. ore probably he obtained it, as he did the desk th bookcase and capacious drawers, now recently ded, from his close personal friend and near ighbour, Thomas Chippendale, who also sold or ve him a sideboard, some chairs, and other articles furniture. The desk, with bookcase attached, der discussion was probably John Hunter's principal iting-desk. Its interior is delicately fitted and ggests Sheraton workmanship, but the whole ain, though graceful effect, is Chippendale. On the iting-flap the great surgeon probably wrote, in the awers below he kept his papers, letters, and MSS., hile the shelves above may have contained part of at "valuable well-chosen select Library of Scarce ooks," to quote the Christie and Manson Hunter le Catalogue of Feb. 1st, 1794; the possession of is library by Hunter has been disputed by those ho will have it that he was an illiterate, but a sale talogue could hardly include the non-existent. he proceeds of this Hunter sale amounted only to e sum of £1300, a sum ridiculously low even in at age, and the price paid by Everard Home for e three bureaux, according to one authority, was £15. ch fine pieces nowadays would fetch at least £100 ch, but comparisons of price do not mean anything hen 130 years have elapsed. To Home the value of e bargain lay in the contents of the secret drawers d the general contents—viz., all Hunter's note- ooks and other manuscripts. These documents are own to have been in Home's hands before the year 00. Very leisurely he poached on their contents d then as leisurely destroyed them. In 1821 he ld William Clift, Hunter's famous disciple, a book- se with drawers, which is now in Scotland, where at e time it belonged to the late Prof. Chiene, and on e same occasion Clift may have bought from him e bureau under discussion. This at Clift's death as bought by Thomas Madden Stone, long known the College as an ardent Hunterian, for 4 guineas, d at Stone's death it was acquired by Miss Margaret unter, a collateral descendant of John and William. appears that when Clift acquired the bureaux he pposed their contents to survive, and it was not ll 1823 that he was shocked by the casual announce- ent, made while they were driving in a post-chaise, at Home had destroyed the Hunter manuscripts, regretted to-day.

The centenary of John Hunter's death was cele- rated in 1893 when an elaborate catalogue by James lake Bailey, the College librarian, recorded the unteriana collected until that date. The additions that collection during 1893–1928 have been con- derable, and include portraits, manuscripts, the unter Baillie volumes of documents, transcripts of ctures, and many small objects once the property of the famous John Hunter. These taken together will form a large exhibit in themselves, and will be shown in the Council Room, the Conservator's Office, and Room IV. of the Museum.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Small-pox and Alastrim.

A NUMBER of experiments on the immunological relationship between small-pox and alastrim have been made in the hygienic laboratory. Monkeys and rabbits were selected for the subjects. Definite cross-immunity was found between alastrim and "mild small-pox" and between alastrim and vaccine virus. The workers conclude that their results establish additional evidence of the identity of the two diseases (James P. Leake and John N. Force, Hygienic Laboratory Bulletin, No. 149, 35 cents). The same bulletin contains a second paper by the same authors describing a method for estimating the potency of small-pox vaccine. They require that a vaccine of "high potency" shall produce a confluent eruption on from 90 to 100 per cent. of the vaccinated area on the back of a rabbit in a dilution of 1 in 1000, and when further diluted to 1 in 3000 the decrease in confluence should not be over 20 per cent. Such a vaccine applied to a 2 mm. scarification in an unvaccinated individual will produce a vesicle not less than 7 mm. in diameter on the seventh day.

"Narcotic Education."

The number of drug addicts in the United States is variously estimated at from 100,000 to over a million. Some influential people who place their faith in the higher estimates organised about two years ago a body with the resounding title "International Narcotic Education Association." Although founded with a good deal of advertisement and in a perhaps unnecessarily alarmist spirit, the organisation has drawn in men of wisdom and experience from all parts of the country who have been formed into departmental committees on a businesslike basis. These committees held their first annual conference last November and the report of their deliberations, just issued,[1] contains matter of considerable interest. The Association has laid down three propositions in regard to drug addiction: "That the cause is ignorance, that the effect is misery, and that the cure is education." But then, as one of the speakers pointed out, "members of the medical profession, scientists, and chemists are among its victims. Is it fair to assume they do not know? What is it they do not know?" His own answer to the last question is that they do not recognise pain as a friendly messenger. One may doubt whether the broadcasting of this information will reduce the number of addicts. Even the experience of addiction seems insufficient education, for only the more optimistic experts expressed faith in any permanent cure.

Education, it is decided, must be supported by, as it must also support, legislation. A drastic model Bill, presented by the Committee on Law and Philosophy, was adopted with amendments to make it still more drastic; so that in its final shape a pedlar who creates addiction in a minor or employs a minor to create addiction is punishable with life imprisonment. Strong pleas that addiction should be treated as a disease rather than as a crime seem to have found expression in the draft legislation only for addicts not charged with crime. It is recognised, however, that heroin addiction results both in criminal tendencies and in an overwhelming desire to create new addicts. It was shown by Dr. J. F. Fisherman, former inspector of prisons for the Federal Government, that great cruelty results to addicts in county gaols from the ignorance of local physicians of proper methods of

[1] Report of the First Annual Conference of Committees of the World Conference on Narcotic Education and International Narcotic Education Association: 662, Southern Building, Washington, D.C. 75c.

treatment. It was also stated, on the same authority, that uncontaminated prisoners form ready victims to addiction through the overtures of confirmed addicts incarcerated with them. In spite of this the model law requires criminal addicts, as well presumably as the pedlars who serve life sentences, to be committed to a penal institution. A rather surprising provision requires that narcotic education shall be included as a "major subject" in the curricula of all public schools.

MEDICINE AND THE LAW.

A Ridiculous Penalty.

THE solicitors' profession is understood to be making progress towards the consolidation and revision of the Acts of Parliament which prescribe its government. If any similar task is undertaken for the Medical Acts, which have as long a pedigree and as tangled a purport as the Solicitors Acts, the question of increasing the penalty for posing as a medical practitioner should be considered. At the Mansion House on Jan. 27th William Faulkner was summoned before Alderman Sir George Truscott for having in December last unlawfully, wilfully, and falsely pretended to be a doctor of medicine, implying that he was a registered medical practitioner. According to the report of the proceedings in the *Star*, the prosecution stated that on defendant's door at Wardrobe Chambers was the name and description, "Dr. S. Boyd Faulkner, M.D. Lond., D.S.C.," though he had no qualifications whatever in this country, and had acknowledged to the Registrar of the General Medical Council that he was not a registered practitioner. The defendant appears to have told the bench that his was a nature-cure establishment, and that he had an electric apparatus; every one of his cases, he claimed, had derived some benefit from his treatment. As Sir George Truscott observed, that was not the question. "The full penalty," said the Alderman, "which I consider wholly inadequate, is £20; you will be fined that amount, and £10 10*s.* costs, or two months' imprisonment." Parliament should take some notice of this judicial comment on the utter inadequacy of the penalty. For a man who has no English qualifications whatever to call himself "Dr. S. Boyd Faulkner, M.D. Lond., D.S.C.," is a piece of impudent imposture fraught with possibilities of grave danger for members of the public whom the Medical Acts are designed to protect.

Professional Secrecy.

Reference was lately made in our columns to recent French discussions of the duty of professional secrecy. Article 378 of the French code was cited in order to contrast the express statutory prohibition which is part of the French law with the ambiguous position of the medical witness in the English law-courts. The discussions in France are continuing,[1] and are usefully analysing the juristical ideas on which the law is based. One idea is that of exemption; the doctor is not obliged to give evidence. This conception seems to leave him a discretionary power of giving or withholding his testimony according to the dictates of his conscience. A quite different idea is that of absolute prohibition, based on the definite interdict in Article 378. To put the matter in another way, the medical witness may be deemed to have an absolute incapacity. Among the implications of the language of the code, four inferences have been evolved. First, it is said, the doctor cannot be heard as a witness even if he consents to give evidence. Secondly, if he does give evidence, judge and jury ought not to take into account what he says. Thirdly, if they do take it into account, the superior court should annul their decision. Finally, the doctor who gives evidence in a court of law can be prosecuted under Article 378. These conclusions are only of academic concern to the medical profession in England where nothing in the nature of an express statutory prohibition has been enacted. In France they appear not to be accepted by the prominent jurists who have written upon the subject. The medical profession in France is evidently dissatisfied with the existing uncertainty; the outcome of the discussions will be awaited with interest.

[1] Bull. de l'Académie de Médecine, 1928, xcix., 76.

River Pollution and Sugar-beet Effluent.

In reports issued last year of the progress made towards purifying our rivers mention was made of the adverse effect of establishing beet-sugar factories. Proceedings have been instituted at Nottingham by the Trent Fishery Board against the Anglo-Scottish Beet Sugar Corporation, though with no conclusive result. It was stated by the prosecution on Feb. 4th that the defendants had already been fined £25; after conviction they could be fined £5 for every day that the offence continued; these and other offenders had been warned that, if the infliction of the original penalty had no effect, the Fishery Board would press for the continuous daily fine until the effluent was properly purified. Biological experiments described by Dr. H. S. Holden indicated that fresh-water shrimps died in seven minutes after being placed in a sample of the effluent from the defendants' premises, and that they lost power to swim after four minutes. Two gudgeon died in little more than half an hour. A civil engineer, giving evidence for the defence, said that every reliable method of dealing with the effluent which he had recommended to the defendants had been put in practice; there were signs of hopeful results from experiments. Mr. William Sutton, an analytical chemist of Norwich, advised delay; in his view things were getting better every year; moreover, he considered that the stream was polluted before it reached the defendants' factory. The case at present stands adjourned for a month.

It is an awkward fact that the two separate functions of the Minister of Agriculture and Fisheries clash irreconcileably in this matter; the encouragement of agriculture is the discouragement of fisheries. According to the report of the proceedings in the *Times*, there was evidence that the Trent occasionally has a run of salmon, about 500 salmon having passed up the river last autumn. The public, which is showing some enthusiasm for the "purer rivers" movement, wonders whether the existing law is inadequate or whether the administration of the law is at fault. It will await the further proceedings with interest.

Spinners' Cancer.

Judge Spencer Hogg, at Oldham County Court on Jan. 26th, had before him an important case in which the question of the legal power given to medical referees under the Workmen's Compensation Act was raised. An application was made by Jane Ann Needham for compensation from the A. C. E. Mill Company, Hollinwood, on account of the death of her husband as the result of spinners' cancer. The husband, who was 65 years of age, had been a cotton spinner for 40 years, but had only been in the employ of the A. C. E. Mill from June, 1925. The respondents contended that he was employed only as an odd man who did not come into contact with mineral oil. After a certificate had been issued by Dr. H. M. Fox, a certifying surgeon, the case was taken to Dr. Judson Bury, medical referee for industrial diseases, who dismissed the mill's appeal and certified that the man was suffering from the disease. It was stated that the man had an ulceration of the neck, and the respondents claimed that this was not due to the employment, and that the onus was on the applicant to prove that it was. The judge said that the decision of a medical referee took the matter out of his hands. If there was an ambiguity in the certificate he would have had jurisdiction; but there was not. The solicitor for the mill remarked that it left the employer in a position of having to pay compensation without the case being heard as to whether or not the disease was the result of the man's employment by the firm. The judge agreed that it really took the jurisdiction out of the hands of those who hitherto dealt with it. He granted the application for £250 compensation, but he granted a stay of execution on the usual terms.

ROYAL SOCIETY OF MEDICINE.

VISIT OF THE SURGICAL SECTION TO CANADA AND THE UNITED STATES.

THE tour organised last autumn by the Surgical ction of the Royal Society of Medicine proved such uccess as to encourage similar ventures in the future. e are indebted to Mr. C. Max Page for this brief tline of the visit.

The party consisted of 25 members, seven of whom re accompanied by their wives. A group of this e is large enough to obtain a considerable reduction railway and hotel rates without being cumber- me to manage. The travel and hotel arrangements re made throughout without a hitch by the Cunard S. Company and the Canadian National Railway mpany, a courier being provided by the ter. Dr. Franklin Martin, Director-General of the nerican College of Surgeons, undertook to get touch with e prominent rgeons in ch place on e itinerary d at every ntre visited e local sur- ons and the spital organi- tions afforded e group a eat welcome. irst-class rogrammes operative rk, and dry nics (to use popular nericanism) re organised. The hospi- lity of our osts," Mr. ge writes, surpassed all pectations a country ready famous this respect. ot only were e entertained the clinics d at clubs, t our hosts were extraordinarily helpful and kind providing motor-car transport and looking after r comfort in every way."

THE SURGICAL SECTION ON THEIR AMERICAN TOUR.

Photograph by Armour & Co.

The Itinerary.

The party crossed in the S.S. *Ausonia* and landed Quebec on August 29th. Six days were spent in nada. At Montreal Dr. A. T. Bazin and Prof. W. Archibald acted as hosts at the General and oyal Victoria Hospitals respectively, and at the tter the Section was fortunate in seeing a thoraco- asty performed by Dr. Archibald. In the evening e party dined at the Mount Royal Club and met rof. Armstrong. At Toronto the group were warmly ceived by Dr. Clarence Starr and saw Dr. Gallie d Dr. Le Mesurier at work. An afternoon was ent at the Toronto Exhibition, and on the following ening some members played golf with Dr. Starr d Dr. Gallie, and the remainder were entertained Dr. Bruce.

A visit was paid to Niagara before proceeding to icago, where, despite our arrival during a week-end hich terminated in Labour Day holiday, a full inical programme had been organised by Dr. reuscher, in addition to various entertainments. n the Sunday the party was conducted by Dr. ranklin Martin over the fine Murphy Memorial which forms a magnificent addition to the home of the American College of Surgeons. We also saw the new North-Western University Medical School, and visited the University Clinic, then nearing completion, in its beautiful surroundings in the University Park. At Chicago the party had its first experience of the intensive operating programmes which our American colleagues know how to stage so well. Interesting operations, in which Dr. Nelson Percy, Dr. Eisendrath, Dr. Cubbins and others took part, were witnessed at the Augustana, Wesley, and Cook County Hospitals. Dr. Franklin Martin entertained the party at Exmoor Country Club on Saturday, and on Sunday a supper party was given by Dr. Kreuscher at the South Shore Club.

After a night's journey the furthest west point of the tour in Rochester, Minn., was reached. Only two days were spent at the world-renowned Mayo Clinic, and they were very fully occupied. Both Dr. C. and Dr. W. Mayo were at home and operated and gave most interesting talks, in addition to entertaining members of the party at their homes. Operation lists, which included some most excellent work by Dr. Judd, Dr. Balfour, Dr. Adson, and Dr. Hunt, made up the surgical programme. On the pathological side the group was fortunate in being present at a weekly meeting of the staff conducted by Dr. H. E. Robertson, and also paid a short visit to the Institute of Experimental Medicine and met Dr. Mann and his co-workers. On the Tuesday night the party dined at the Rochester Country Club, and heard Dr. Mayo, Dr. Wilson, and Dr. MacCarty speak. Returning via Chicago, the party was entertained by Messrs. Armour, and a visit to their stockyard and factory proved an interesting experience. The photograph here reproduced was taken at this stage of the tour.

At Grand Rapids the programme was arranged by Dr. Ferris Smith, and was of particular interest on account of the first-class work witnessed in hospitals smaller than those so far visited. The Butterworth and St. Mary's Clinics were in structure and equipment as advanced as any that were seen in course of the trip. In the evening the party was entertained by the Kent County Medical Society. At Detroit the reception was more than hospitable under the kindly management of Dr. Kelly. Sunday was spent on a yacht trip on Lake St. Claire. The next morning was spent with Dr. MacClure at the beautiful Ford Hospital, and in the afternoon a tour of the Ford factory at Rouge Park, together with a visit to the Ford air port and trip over Detroit on a large passenger plane, made a memorable day. The party met Mr. Ford and his son, and were given an opportunity to see and try their new car. On the following day the Harper Clinic and Receiving Hospital were visited in the morning, and the Jefferson Clinic and Parke Davis Works in the afternoon. The journey to Cleve-

land was made by the night boat, and a very full day was spent with Dr. Crile at his new clinic—an operation list of 12 was completed with characteristic vigour and punctuality by 11.30 by Dr. Lower. A number of short papers by members of the staff followed a visit to the experimental department. After tea and dinner with Dr. Crile the party left for Baltimore. The party experienced a definite change of atmosphere touched with an agreeable southern flavour on their arrival in Maryland—emphasised by the fact that the thermometer rose to 97° F. during their stay. The Baltimore programme was (mercifully under the climatic conditions) confined to the Johns Hopkins Clinics. Operations by Dr. Hugh Young, Dr. Finney, Dr. Dean Lewis, and Dr. Dandy were witnessed, and Dr. Bloodgood gave a demonstration of bone tumours and discussed their diagnosis. Here the party had the pleasure of meeting the doyen of American surgery, Dr. Kelly. Dr. Hugh Young entertained the party at a country club in the evening. Some members visited Washington on the following afternoon, while others went to an outlying hospital with Dr. Bloodgood.

Philadelphia was unfortunately reached on a Saturday, but a full programme was staged. Five surgical clinics were working in the morning in different parts of the city. Most of the party visited the Jefferson Hospital and watched Dr. Chevalier Jackson and Dr. Gibbon at work. Dr. A. Ashhurst was operating at the Episcopal Hospital and Dr. Charles Frazier at the University Hospital. In the afternoon Dr. John B. Deaver carried through a long list at the Lankenau Hospital. The party was entertained at the Penn Athletic Club in the evening and at Dr. Jopson's home on Sunday.

New York was reached the following day, and in the three days at disposal choice was more than usually difficult among the wealth of clinical material available. Most of the party visited the Post-Graduate Hospital and watched Dr. Albee and Dr. Erdmann. On Thursday Dr. William Coley was visited at the Hospital for Ruptured and Crippled. The afternoon was most pleasantly spent in a yacht trip up the Hudson with Dr. George Stewart, most of the party at this stage of the tour being ready for a half-holiday. On Wednesday an interesting symposium in cancer treatment by X ray and radium was given at the Memorial Hospital and afterwards an excursion was made to the amazing new building which is to become the New Columbia Medical Centre. The visit of the party to the Rockefeller Institute where Dr. Noguchi and Dr. Eberling gave fascinating demonstrations was unfortunately cut short by the necessity of catching a train to Boston.

Boston was the last centre to be visited, and most of the party felt sorry to have a bare two days to spend in a city of such historic associations. Prof. Harvey Cushing entertained in the morning at the Peter Brent Brigham Hospital, and later the party went to the General Hospital, a pleasant old foundation with modern additions. In the evening we were entertained at Brookline Country Club. On the following day Dr. Osgood and Dr. Ladd gave us a first-class clinic in their most delightful Children's Hospital, and subsequently Dr. Lahey was seen operating at the Deaconess Hospital. An interesting diagnostic clinic by Dr. Joslin, Dr. Fordan and others concluded our medical experiences.

The Return.

The party returned to New York by train and embarked direct on the S.S. *Lancastria*, glad enough to have a rest, for the infectious enthusiasm of their American hosts had kept an active interest from the start to the finish of the journey. Mr. Page writes of the sense, shared by all the party, of having completed a memorable and inspiring experience. The whole party was strongly impressed by the high standard of surgery which is widely attained in the States, and was filled with admiration for their energy and organisation. From a surgical point of view, in the short time at disposal the able staff work made it possible for the group to see a great deal interesting work, and to obtain an insight in various phases of American life.

The names of those taking part in the tour we as follows: F. Belben (Bournemouth), J. A. Ber (Guy's), R. B. Blair (Hull), E. J. Bradley (Stafford A. H. Burgess (Manchester), H. B. Butler (Guildford L. D. Callander (Doncaster), E. F. Finch (Sheffield W. Gilbert (Port Elizabeth), W. Lennox Gord (Cape Town), C. B. Heald (London), F. S. Hean (Liverpool), J. J. Kearney (Cork), I. Macdona (Huelva), P. H. Mitchiner (St. Thomas's), C. M. Page (St. Thomas's), J. Howson Ray (Mancheste Winifred Ross (Dulnain Bridge), J. J. M. Sha (Edinburgh), E. W. Sheaf (Guildford), G. B. Ston (Kleinfontein), M. P. Susman (London), J. H. Wats (Burnley), J. Whittingdale (Sherborne), J. B. Wilson (Sheffield).

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The National Cancer Campaign (Ireland).

DURING the past few months several influent meetings have been held in provincial towns in supp of the National Cancer Campaign (Ireland). Last we a successful meeting at Wexford followed meetin previously held at Nenagh and Limerick. Ea meeting was addressed by members of the Cent Council from Dublin, as well as by local speake Cordial support is being given by the medical professi in each centre as well as by the local clergy of churches. In each town where a meeting is held committee is organised in order to maintain interest the movement, both by further propaganda and collecting funds. An active branch of the campai has been organised in Belfast where a public meet will shortly be held.

Charge of Blackmail against a Medical Man.

Last Saturday, before the district justice at Killal Dr. Henry Vincent McKeogh, medical officer Portroe dispensary district, was charged with hav "feloniously, with threats and menaces, demand of Dr. Patrick J. Holmes the sum of £300, with int feloniously to steal, take, and carry away the s £300." Dr. Holmes is medical officer of the Killa dispensary district. Evidence was given t Dr. McKeogh had threatened to complain of Holmes to the General Medical Council, had offered hold back his complaints if Dr. Holmes was will to "meet him half-way," had asked for a sum of £3 and had actually been paid £200. The justice fou that a prima facie case had been established and returned the accused for trial at the next Circuit Co at Ennis, bail being allowed.

MANCHESTER ROYAL INFIRMARY.—During the p three years there has been a decrease in the deficit acco of the Manchester Royal Infirmary and the Barnes C valescent Hospital, Cheadle. For the financial year j closed the deficit was £10,847, compared with £18, in 1926 and £22,740 in 1925.

RIVER POLLUTION.—At a meeting of the Jo Advisory Committee on River Pollution, held on Feb. 2nd 3rd at the Ministry of Health, evidence was taken from West Riding of Yorkshire Rivers Board, the Mersey Irwell Joint Committee, the Ribble Joint Committee, Thames and Lee Conservancies, and the Tame Basin Jo Committee, all whose witnesses were unanimously of opinion that the proper unit for administration purp was the watershed. In large watersheds such as the Tr it might, however, be desirable for the watershed board work through subsidiary bodies in order to utilise to the local knowledge and zeal. There was some divergence opinion as to whether land drainage and pollution pow should be combined in the one authority. The gen trend of the evidence went to show that results were achie much more by persuasion and advice than by legal proce ings, but that these methods could only be used effectiv where there was an adequate technical staff.

Public Health Services.

Antituberculosis Schemes.

All administrative tuberculosis officers were asked furnish the Ministry with very full returns of the ork done under their schemes in 1926. The Ministry as just issued to all the county councils, county orough councils, and tuberculosis joint committees England an analysis of these returns, designed to ve some idea of the scope and character of the work each district. An explanatory statement suggests at the local authorities should make comparisons of eir work with that of other districts of similar size id type with a view to considering whether they e getting the best possible for a given financial itlay. The analysis consists of tables with 46 columns ving particulars for all the districts. Cols. 1 to 3 ve the population, deaths and death-rate from berculosis. Cols. 4 to 6 deal with the efficiency of tification and of the revision of the registers. Col. 7 ves the proportion of the total tuberculosis cases alt with under the scheme. Cols. 9 to 12 deal with e extent to which contacts and suspects come up to e dispensary for examination; cols. 8, 13, and 14 with e amount of delay in arriving at a diagnosis; cols. and 16 with the use made of sputum examinations id X rays. Col. 17 gives a measure of the coöperation tween tuberculosis officers and general practitioners, id cols. 18 and 19 of the amount of supervision given tuberculous patients in their homes. Cols. 20 and provide striking evidence in some cases of the ilure to carry out the provisions for domiciliary eatment by insurance practitioners. Cols. 22 to 46 al with residential treatment, and it is suggested at a study of cols. 31 to 38 may help to secure a ore economical use of available residential accom- odation. A superficial glance through the long sts of figures shows an extraordinary discrepancy tween one district and another which would appear indicate a great variation in methods.

We suggest that when the next analysis is issued it ould add to the interest if two more columns were dded, one to show the cost of each scheme, say, per 000 of the population, or, perhaps preferably, per 0 deaths from tuberculosis (as the Ministry pays a per cent. grant this figure is readily available), and e other to show the percentage reduction in the ath-rate from tuberculosis in each district during, y, the last ten years. The acid test of the efficiency the schemes is "Are they delivering the goods?"

Name of town.	Taken from Sheffield report for 1926.	Taken from the Ministry of Health analysis for 1926. All the numbers are per 100 deaths from tuberculosis.			
	Percentage reduction in tuberculosis death-rate—1917–26.	"New" cases examined by tuberculosis officers.	"Contacts" examined by tuberculosis officers.	Hospital beds available.	Patients treated in hospitals.
ortsmouth	52·4	227	31	39	89
heffield ..	49·8	688	287	114	381
lymouth ..	47·7	231	390	73	146
eicester ..	33·3	249	30	61	178
ewcastle-upon-tyne	32·3	223	17	42	99
alford ..	27·6	175	142	47	150

The Ministry attaches great importance to the use the dispensary for consulting purposes and to the xamination of contacts. We have before us a table the Sheffield health report for 1926 which shows the percentage reduction of the tuberculosis death-rate during the last ten years in the county boroughs of England and Wales with populations over 200,000. The three towns with the largest reductions are Portsmouth, Sheffield, and Plymouth, and the three with the smallest Leicester, Newcastle, and Salford. The above table shows how these six towns compare as regards the examination of new cases and contacts at the tuberculosis dispensary and the provision and use of hospital beds. It also gives an illustration of the discrepancy alluded to above.

A Squabble about Scarlet Fever.

A discussion which arose last month in the council of a Midland rural district has some general interest. According to the report which we have seen one or more of those present suggested that there was some doubt whether a case of scarlet fever reported by the medical officer really was that complaint at all, though the patient had been removed to hospital on the family doctor's instructions. The chairman remarked that it was a serious matter for a patient to be in hospital for six weeks at a cost to the district of 18 guineas if there were any doubt about his complaint. It was then recalled that on the occasion of a previous dispute the medical officer had declined to visit the cases of his brother practitioners because it would be a breach of professional etiquette for him to do so. A councillor, defending the action of the medical officer, stated that the Ministry of Health had laid it down that a medical officer should not be required to visit the cases of another practitioner. To this the reply was made that the Ministry's ruling was that while a medical officer could not be expected to visit every case of infectious disease it was advisable for him to do so when it was a question of diphtheria or scarlet fever, but this was a matter for each sanitary authority to decide for itself. It is doubtful whether such a deduction could be made from the paragraph relating to infectious diseases in the latest memorandum on the Duties of Medical Officers of Health in England and Wales (using its short title). This paragraph contains the following passage:—

"On being informed of the *outbreak* of any infectious or epidemic disease of a dangerous or unusual character within the district it is essential that he should visit the spot at once in order to inquire into the causes and circumstances of the outbreak and to take such measures for the prevention of disease as he is legally authorised to take under any Statute or Regulation in force in the district. He should also investigate any doubtful or suspected cases of dangerous infectious disease of which he learns. If in any case he is not satisfied that all due precautions are being taken he will, of course, advise the persons competent to act as to the measures which appear to him to be required to prevent the extension of the disease.

"In conducting such investigations a medical officer of health will bear in mind that the examination of patients in their own homes can be made only with the consent of the patient or of those in charge of the patient. If a medical practitioner is in attendance his coöperation should always be sought."

For administrative purposes an *outbreak* may be taken to mean several cases apparently arising from a common source; scarlet fever is, of course, included in the legal definition of infectious disease of a dangerous character. Seeing that rural areas are the places where the milk-supply of towns is produced the medical officer will always bear in mind the possibility of infection of the milk; to secure the early diagnosis and isolation of any person suffering from an infectious disease transmissible by milk and so situated as to be likely to infect the milk is a matter of importance, not only to the rural community, but also to the various urban communities supplied. The Ministry will therefore expect the medical officer to satisfy himself as to the nature of any doubtful or suspected cases of dangerous infectious disease. Where he is a whole-time official there is but little danger of his visit to a patient affecting the practitioner's interest adversely. Where he is not the care of the public health is still the first consideration.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 28TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 370 (last week 405) ; scarlet fever, 1981 ; diphtheria, 1644 ; enteric fever, 64 ; pneumonia, 1409 ; puerperal fever, 48 ; puerperal pyrexia, 110 ; cerebro-spinal fever, 9 ; acute poliomyelitis, 13 ; acute polio-encephalitis, 4 ; encephalitis lethargica, 27 ; dysentery, 3 ; ophthalmia neonatorum, 112. There was no case of cholera, plague, or typhus fever notified during the week.

The cases of small-pox were notified from the following 24 counties :—London 4 (Southwark), Bedford 8 (Bedford), Derby 12, Durham 72, Gloucester 3 (Bristol 2), Hertford 2 (Barnet), Lancaster 25, Leicester 1 (Hinckley), Lincoln, Parts of Kesteven 1, Parts of Lindsey 2, Middlesex 1 (Uxbridge), Northampton 1 (C.B.), Northumberland 14, Nottingham 24, Salop 1 (Drayton R.D.), Southampton 1 (Hartley Wintney R.D.), Stafford 1 (Burton-on-Trent), Surrey 2 (Chertsey, Guildford), Sussex East 2 (Hastings, Cuckfield), Sussex West 1 (Worthing), Warwick 29, (Birmingham 17), Yorks North Riding 19 (Middlesbrough 11), West Riding 57, Glamorgan 24, Monmouth 63.

The number of patients at the Infectious Hospitals of the Metropolitan Asylums Board on Jan. 31st–Feb. 1st was as follows :—Small-pox 10, scarlet fever 1776, diphtheria 2559, enteric fever 22, measles 1308, whooping-cough 161, puerperal fever 17 (plus 14 babies), encephalitis lethargica 70, poliomyelitis 2, " other diseases " 48. At St. Margaret's Hospital there were 11 cases of marasmus and 16 babies with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were 2 (0) deaths from small-pox, 1 (1) from enteric fever, 102 (49) from measles, 4 (0) from scarlet fever, 31 (4) from whooping-cough, 34 (6) from diphtheria, 39 (5) from diarrhœa and enteritis under two years, and 96 (24) from influenza. The figures in parentheses are those for London itself. The 2 deaths from small-pox belonged to Bradford C.B. (See note last week.) Of the 53 fatal cases of measles outside London, 13 were reported from Manchester, 11 from Bristol, 4 from Derby, and 3 from Brighton, while the figures from Glasgow and Dublin for the same week were 33 and 10 respectively. The number of stillbirths registered during the week was 296 in the great towns, including 51 in London.

JOINT TUBERCULOSIS COUNCIL.—At a council meeting held at the House of the Society of Medical Officers of Health on Jan. 21st Sir Henry Gauvain was elected chairman for 1928, Dr. Lissant Cox vice-chairman, Dr. E. Ward hon. secretary, and Dr. J. Watt hon. treasurer, the other members being Dr. S. Roodhouse Gloyne, Dr. A. Neville Cox, Dr. L. S. T. Burrell, Dr. Peter Edwards, and Dr. Jane Walker. Dr. W. Brand reported that 29 persons had attended the course of post-graduate study at Victoria Park Hospital. Future courses had been planned as follow : In June next a course at Alton in surgical tuberculosis ; in July a course at Papworth and Cambridge with the coöperation of Sir Humphry Rolleston, Dr. P. C. Varrier-Jones, and Dr. Louis Cobbett ; in October a probable course at Edinburgh. At a luncheon following the meeting there were present as guests Sir Robert Philip (President of the B.M.A.), Sir StClair Thomson (President of the Tuberculosis Society), Dr. Rufenacht Walters (President of the Society of Superintendents of Tuberculosis Institutions), and Mr. G. Elliston (secretary, Society of Medical Officers of Health). Sir George Newman delivered a short address to tuberculosis workers in which he expressed his belief that the fight against tuberculosis was being won, the dispensary system being the winning factor. He believed that in turn and in this order we should defeat tuberculosis, rheumatism, syphilis, and cancer. The four mainstays in the tuberculosis campaign were : (1) Notification, which brought the practitioner into touch with the tuberculosis service. (2) The dispensary. He noticed that in some districts the sputum examinations were too few (at least three should be made in every negative case) ; in other instances X rays were not sufficiently utilised. (3) The sanatorium, the success of which depended on fresh air, moderate and controlled exercise, employment, and good food. The need at sanatoriums was for a greater study of the requirements of individual cases. (4) After-care. In this the practitioner and after-care organisations each played an important rôle. Our ideal should be sooner or later to make possible for everyone the sanatorium conditions of life as regards housing, exercise in the fresh air, and good food.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. G. S. Rutherford to be Surg. Lt. Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Lt.-Comdr. H. C. Hedderwick is placed on the Retd. Lis
Surg.-Comdr. F. H. Watson is placed on the Retd. Lis

ROYAL ARMY MEDICAL CORPS.

Majs. F. B. Dalgliesh (and is granted the rank of Lt.-Col and C. M. Rigby retire on retd. pay.
Capt. T. C. Bowie to be Maj.
Capts. to be Temp. Capts. and temporarily relinquis the rank of Capt. : B. D. Merrin and J. B. Woodrow.
Temp. Lt. I. MacW. Bourke relinquishes his commn.

ARMY DENTAL CORPS.

R. W. Mather to be Lt. on probation.

TERRITORIAL ARMY.

Maj. (Prov.) A. H. Fullerton is confirmed in his rank.
Capt. W. Lumley, late R.A.M.C., to be Capt.
Lt. F. N. Foster to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. J. B. Jamieson, having attained the age-limit, retd. and retains his rank with permission to wear th prescribed uniform.
Maj. J. A. Davies, having attained the age-limit, is ret and retains his rank with permission to wear the prescribe uniform.
Capt. B. Holroyd, having attained the age-limit, relir quishes his commn. and retains his rank.

ROYAL AIR FORCE.

Flying Officer Neil Innes Smith is promoted to the ran of Flight Lieutenant.
Flight Lts. J. J. Clarke and B. Pollard are transferred t the Reserve, Class Dii.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. G. R. Nodwell is transferred from Class Di to Di

The King has approved of the award of the Royal Nav Volunteer Reserve Officers' Decoration on Surg.-Comdrs T. Turner and A. E. W. Hird.

THE LATE LIEUT.-COL. ROBERT TILBURY BROWN

Sir Patrick Hehir, under whom Tilbury Brown serve for 21 months (1911–13) as D.A.D.M.S. (Sanitary), Burm Division, sends us the following appreciation. An obitua notice appeared in THE LANCET of Jan. 28th, p. 207.

" He was," writes Sir Patrick Hehir, " the best practic military sanitarian that I have known. I looked on him as born sanitary officer. We were twice on division manœuvres together, once in the Northern Shan Hills ar once on the banks of the Taiping River on the borders China, both in bamboo country. In the former we we encamped on the edge of a swamp with trickling strean from rice-fields as seemingly our only source of water-suppl In a few hours he found a spring on high ground and in half-hour bamboos raised on bamboo stanchions brought th water to our 400-gallon iron tanks in which it was chlorinate On the banks of the Taiping (our headquarters for the tin being) he created one of the most beautiful and sanita camps I have ever seen ; nothing was left unthought c He had remarkable sanitary intuition and a genius f detail, and, being a good draughtsman, worked out h schemes on paper in a few minutes and then saw the carried out. During the time we worked together in Burm mainly through his personal exertions and talent, the deat rate in the Burma Division was reduced 50 per cent. ar the malaria-rate 74 per cent. In Burma he repeated suffered from gastro-intestinal trouble and at one time were afraid that he was suffering from sprue. I ascertain from many senior officers who were with him in East Afri that he did most laudable work there under exceptional severe circumstances in a trying climate. Besides being a excellent sanitarian he was a sound physician and a goo bacteriologist. He was a good companion and a mo loyal man to work with."

SOUTHWARK GENERAL LYING-IN HOSPITAL.—Th hospital is appealing for £40,000 to rebuild the out-patient department and the nurses' quarters. Last year there we 36,000 attendances in the antenatal, postnatal, and dent clinics, and there was not a single death among mothers children. There is said to have been no appeal on behalf the institution since 1765, the year of its establishmer when Garrick gave benefit performances at Drury-lane.

MOTOR-CAR ACCIDENTS AND HOSPITALS.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 22nd last you kindly published a letter from me asking for details of motor accidents treated at hospitals throughout the country. Figures reached me from 183 hospitals, representing 1169 beds (rather less than one-third of the total available beds) and it appears that the cost to the hospitals of the country, irrespective of any fees to medical men, must be in the region of half a million pounds sterling annually. The financial burden placed upon the hospitals is unbearable, and in other respects almost unbelievable. For instance, I find that in many small hospitals the medical officers have been impelled, as the week-end approaches, to hasten the discharge of in-patients, most of whom are local accidents for whom the hospital was founded, in order to have beds ready for motorists from "foreign parts."

The Hospitals Motor Accident Policy Association, of which I am chairman, have placed these statistics before various insurance experts, and I am glad to say that in a very public-spirited manner the Eagle Star and British Dominions Insurance Company, Limited, have established a policy, which for the moderate premium of 5*s.* guarantees to the hospital a payment of 10*s.* 6*d.* per day up to 30 days should the insured be admitted into the hospital as the result of an accident caused by any moving public or private motor, electric, or horse-drawn vehicle, together with a payment of 3 guineas for medical fees, which is increased to 5 guineas should the patient be detained beyond seven days. In the case of patients dealt with in the casualty department and not admitted, the payment is 10*s.* 6*d.* to the hospital and 10*s.* 6*d.* to the medical officer. Whilst greatly appreciating the action of the Eagle Star Insurance, this Association is not satisfied that the position has been adequately dealt with, but they feel that a start has been made to lighten the burden which the hospitals have been obliged by circumstances to shoulder, and they trust that further experience may enable them to secure even better provision.

Every motorist carries a map and every motorist should have an M.A.P. (Motor Accident Policy); so also should the "man in the street," and the patron of the motor-bus and taxicab. These policies will be ready for issue this week, and I am asked to suggest that intending holders should make their cheque in the form of a banker's order to be paid annually. They will thus avoid personal inconvenience and all something like 5 per cent. to the amount available for distribution amongst the hospitals. The cheque should be made out in this way:—

"Pay now and annually on this date to the Eagle Star Insurance, 1, Threadneedle-street, E.C., the sum of £ ."

(and please write plainly) and send it to the Hospitals Motor Accident Policy Association, 6, Duke-street, Adelphi, W.C.

One interesting feature is that a motor owner may take a policy for each seat in his car. Another feature, important for motor cyclists, is that on account of the risk the company can only pay half benefit in respect of motor cyclists and sidecars; motor cyclists are therefore urged to take two policies for each seat, which will give them full cover.

I am, Sir, yours faithfully,

H. W. BURLEIGH,
Chairman, Hospitals Motor Accident Policy Association.

Feb. 4th, 1928.

FATALITY-RATES OF SMALL-POX IN THE VACCINATED AND UNVACCINATED.

To the Editor of THE LANCET.

SIR,—Dr. Garrow's figures are based upon the fallacy of comparing statistical incommensurables. As he must know well, there have been two distinct types of small-pox occurring in England during the last few years; the vast majority have occurred in the unvaccinated populations of the Northern and Midland counties, and were of the mild type—variola minor, if he likes so to term it—whilst a very small number of a severe type—variola major—have occurred in the south of England, due to infection introduced from France, Spain, &c. This distinction is not apparent in the tables published in the annual reports of the chief medical officer to the Ministry of Health, though doubtless the necessary information is available at the Ministry. By comparing the information in these tables, from which he quotes, with the accompanying text, and with the figures given in Table XL. of the Annual Statistical Reviews of the Registrar-General, I have been able to identify nearly all the deaths. In this manner I obtain the following table of deaths in England during the years 1923 to 1926:—

Age.	Vaccinated.	Unvaccinated.
Under 15 ..	0	17 (probably all northern)
15 to 30 ..	1 (? northern)	2 (1 northern, 1 southern)
Over 30 ..	12 (3 northern, 9 southern)	2 (1 northern, 1 not identified)
Total ..	13	21

By "northern" is meant the northern and midland counties as defined by the footnote to Table IV. of the Registrar-General's statistical reviews, less Middlesex, Herts, and Essex, the remainder being the southern counties.

Assuming, then, that all the deaths in the southern counties were deaths from variola major, we may deduct them from the total deaths; this assumption is quite valid, as these deaths can be identified from the text; identification of the cases is not easy, but as those occurring in the south of England were very few—about 80—they may be neglected statistically. The amended table is as follows:—

Ages.	Vaccinated.			Unvaccinated.		
	Cases.	Deaths.	Fatality-rate.	Cases.	Deaths.	Fatality-rate.
0–15 ..	28	0	—	10,709	17*	0·158 ±0·026
15–30 ..	392	1	0·25 ±0·17	5,296	1	0·019 ±0·013
30 and over	3,618	3	0·08 ±0·03	1,713	2	0·117 ±0·070
Total ..	4,038	4	0·10	17,718	20	0·112

* 10 were under 1 year old.

These figures are probably accurate as far as they go, except that the small number of cases of variola major in the southern counties are included; the table gives the fatality-rates from mild small-pox in the vaccinated and unvaccinated, the advantage being in favour of the vaccinated, except at ages 15 to 30 years, where, the rates being based on a single death in each class, no deduction is possible from such meagre data. The probable error in all classes, except the youngest class of unvaccinated, is very high. Even when corrected there is a further fallacy as two of the three deaths among the vaccinated at ages over 30 years were of persons aged over 70, whilst only one death at those ages occurred among the unvaccinated. It is well known that small-pox fatality rises steeply in the later years of life. The data do not form a basis of comparison for the fatality-rates in variola major among the vaccinated

and unvaccinated, but this may be ascertained from the data of other epidemics—e.g., those given in Table II. of Dr. W. Hanna's "Studies in Small-pox and Vaccination," published in 1913.

I am, Sir, yours faithfully,

C. O. STALLYBRASS.

Public Health Department, Liverpool, Feb. 6th, 1928.

THE PRESENT POSITION OF THE VOLUNTARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—Prof. Hey Groves, in your issue of Feb. 4th, arrives at a conclusion in favour of State control of hospital services by omitting consideration of fundamental principles which inspire individuals to voluntary effort. Ultimately the voluntary system of hospital management rests upon the desire of a multitude of individuals, at the head of which are the groups of men having knowledge of business, in this country commonly known as boards of governors, in the United States as boards of trustees. The whole of Prof. Hey Groves's list of arguments is rendered fallacious because he seems only to consider the voluntary work of physicians and surgeons—quite apart from the question how far that work can be called purely voluntary, the chief distinction is the freedom of the individual, unfettered by bureaucratic limitations, to apply his special talent to the improvement in treatment of the particular cases which happen to come under his care. Of far more importance in the voluntary system are the men of business, who give up a large amount of time, not "an occasional hour," to the control whether of single institutions or in coördinating the activity of many. It is these boards of governors—boards of trustees—who are the centre of the voluntary system. It is to them that gifts, small or great, are entrusted; it is to them that large sums are given without conditions by the donor during his lifetime. To them there are made bequests without such conditions as the future might render onerous.

Prof. Hey Groves, not in one passage only, shows that he is out of sympathy with boards of governors and such-like bodies in his own city. Moreover, his information is partial, derived too exclusively from medical men in the United States, which ignores all that is there of primary importance, the management of the hospitals by boards of trustees. His commencement gives his case away. It is based on the support of "very many medical men, who have given it their support and by the very few who have come forward to defend the voluntary system." He proceeds to beg the question—"Already the purely voluntary system has disappeared." That may be a truism—"In the original meaning of the term the voluntary system is already dead." That is the reverse of a truism. The voluntary principle is working more actively than ever, whether here or where Prof. Hey Groves seeks for support, in America. What is needed is better coördination with the State and municipalities.

That the voluntary system is out-distanced by more progressive countries is a statement of opinion which can be countered by a close inquiry among the actual patients in hospitals. It is sufficient for this country to point to the long waiting-lists at the voluntary hospitals on the one hand, and, on the other, to the empty beds in the buildings which Prof. Hey Groves so much admires. He drags in the question of the middle classes, again a matter for coördination, the closer association of nursing homes with the voluntary hospitals, schemes for sick insurance, &c.

Some of Prof. Hey Groves's remarks concerning recent history are strange. One great success of the Army Hospital System during the late war was the atmosphere brought in by the medical staffs and nurses from the voluntary hospitals, which both expanded and relaxed the rigidity pre-existing under military traditions. In his reference to nursing and Miss Nightingale, he forgets the truly English system of nursing developed by the voluntary work of William Rathbone and Sister Agnes Jones in Liverpool. He says much research. There is research in which the investigat plunges into the mist of the unknown, and produc print and figures as part of the requirements of salaried post. There is also research by one servi at a voluntary hospital, with freedom to study sor peculiarity of a special case, and perhaps thereby add one more stepping-stone for the crossing of river hindering progress.

Dr. Graham Little and I, in a communication the *Times*, have suggested conferences, particular between those mentioned above, who are acquaint with the business side of voluntary hospitals, a those of municipal hospitals, such as we know connexion with King Edward's Hospital Fund a the University of London, so far as concerns t metropolitan area. There are similarly active bod of men in municipal and county areas. The obj of such conferences may be achieved by the establis ment of "advisory councils for hospital service On such councils we rather count physicians a surgeons as among those to be called upon for spec advice. We suggest a way by which further develo ments of voluntary effort and freedom of resear may be coördinated with State and municipal expen ture. Individual effort will be encouraged; outl derived from rates and taxes restricted. It is solution of a practical kind, whereas the propo made by Prof. Hey Groves is an impossible o the burden on the tax and ratepayer would be p hibitive in amount. The "essentials of a go hospital system" (pace Prof. Hey Groves) can summed up in one word—coördination.

I am, Sir, yours faithfully,

London, Feb. 6th, 1928. WALTER G. SPENCER.

To the Editor of THE LANCET.

SIR,—Prof. Hey Groves and I obviously stimul each other to a renewed conviction that our o views are correct, and we must therefore, I thi agree in all friendliness to differ. In his latest arti however, I think I can detect certain inconsistencie a detection which I hope will convert some reader my point of view. The issue surely is a simple c much simpler than Prof. Hey Groves describes it. is whether all our hospitals shall in future be mana by public authorities or whether those which are n under private management shall continue to be administered. Both systems of management—(1) public authorities, (2) by private administration—h been tried out in our country and have resulted in very different types of institution, the "voluntar hospital and the municipal or poor-law hospital. estimation in which these two types are at the mom relatively held must surely be taken as some indicat of the value of these two systems compared with e other. Prof. Hey Groves's conception of the volunt hospital is tinged with prejudice and does not corre represent the facts. For example, is it really the c as he states, that the acceptance by the volunt hospitals of the Parliamentary grant of £500,0 made immediately after the war to recoup the hospi in some small measure for the sacrifices which t increased services to the State during the war entai is "a violation of voluntary principles?" I pur to expose some of Prof. Hey Groves's inconsisten by the mere juxtaposition of statements made by Prof. Hey Groves writes that "one of the essent of the voluntary system" is that "it is a cha bestowed by the rich upon the poor." A little l he cites as one of the most important charges aga the voluntary system the fact that "it has faile meet the growing need of the middle classes." apparently sees no incongruity between these statements! The voluntary hospital by its nature has not yet been expected to deal with middle classes. It is the changed position of t classes, of recent development which calls for help hitherto required. Again, in his summary he st that "an efficient hospital system" would call "effective fusion, coördination, or coöperation betw all hospitals of every kind and variety in given a

s fusion must be under the control of the Ministry Health." Immediately succeeding this pronounce- it he declares that another essential of an efficient pital service is that "there should be State aid out State control." I submit that these two ements are destructive of each other, unless he some ingenious quibble to show that control by Ministry of Health is not State control.

nasmuch as the title "voluntary" seems to be able of ambiguity it might be preferable to use the d "independent," which would emphasise the linal principle for which the upholders of the ntary system are contending—namely, manage- t of hospitals by bodies essentially independent of State or municipality. Prof. Hey Groves seems e somewhat confused on this point, and perhaps nd I are in effect in more essential agreement in views than appears on the surface, for as I wrote our issue of Jan. 21st, it is the voluntary (or pendent) system of management which I am erned to maintain, and not so much the system oluntary contributions. That system of manage- t entails, I think, a very large measure of "free ical service," which is one of the five qualities uded by Prof. Hey Groves in his enumeration of essentials of the voluntary system. A corollary his freedom is a staff preponderantly officered by ons not paid for their professional services and con- iently preserving complete personal independence. harles Lamb, spending an evening with a party Scotsmen, expressed the amiable wish that their onal poet Burns could drop in, whereupon of the company rose as one man to point out that was impossible, as Burns was dead. Prof. Hey ves must, I think, be a lineal descendant of these Scotsmen. I wrote: "We owe it to the voluntary pitals that Sairey Gamp has been finally displaced Florence Nightingale." I fondly imagined that was a terse and picturesque way of saying that the dard of nursing in England had improved since kens created his famous character, and that the provement was due to the training initiated and ected by the voluntary hospitals. Prof. Hey ves construes my script literally; he recites with essorial prolixity the biography of Florence htingale, to show that she received much of her ning abroad, not in voluntary hospitals, and he mnly rebukes me for being "inaccurate and leading" in making the statement quoted!

rof. Hey Groves writes under his list of "failures he voluntary system" the following sentence: ost important of all, it has utterly failed to dinate the hospital services necessary for the munity." I would venture to refer him to the cles in the *Times* of Jan. 10th and 11th, contributed Mr. Walter Spencer and myself, in which we onstrated that a very large measure of coöperation veen hospital services in certain areas has in fact n silently accomplished by the voluntary hospitals ng the lead which their outstanding prestige has eded them, in coöperative schemes for medical ices within their area of operation, but I freely it that this coöperation has been imperfect and some ways haphazard, and Mr. Spencer and I gested a scheme for the future which would preserve them a management essentially independent of the State (upon the analogy, which we cited, of the versities), while ensuring a larger measure of dination between hospital services.

rof. Hey Groves conveniently ignores the question the comparative cost of the two systems of nagement. Sir William Collins,[1] writing with the complete municipal and Parliamentary know- e derived from his position as Chairman of the L.C. and Chairman of Committees of the House of Commons, specifically stated in 1912 that—

> if the hundred odd voluntary hospitals of London were on the rates and staffed and managed after the fashion, of the Metropolitan Asylums Board institutions, it ld mean a new charge of something like 8*d.* in the id on the rates."

[1] Hospitals and the State. Harrison and Sons. 1912.

Inasmuch as his estimate was made in 1912 it is obvious that the figure would now be practically doubled, that being the ratio in which the cost of all hospital services has increased since 1913. My contention in my address in your issue of Dec. 17th was that we could not indefinitely go on piling up the burdens upon our ratepayers, already the most heavily taxed in the world; that economical use of our scanty resources was the crying need of our time. One of my paragraphs on this subject is as follows:—

> "The administration of the voluntary system is incomparably cheaper, because it is voluntary, than any State-controlled system could be. Moreover, the purposes to which money under State control would be applied would probably not be the same as those upon which voluntary hospitals are concentrated. They would be inferior purposes in every case, and the waste of money consequently would be even more disastrous than the actual expenditure would indicate."

This economic aspect, I submit, is of cardinal importance, and it is a comfort to me personally to reflect that economic considerations alone will in all probability effectively block for this generation at least what I submit would be the extremely wasteful substitution of State management for independent management of hospitals. I cannot envisage the political party which will be anxious to add a rate of something like 1*s.* 4*d.* in the pound in order to transform the highly popular voluntary hospital into a copy of the highly unpopular poor-law infirmary.

Dr. J. C. Muir, in his letter in your issue of Jan. 28th, has dropped a much larger brick than he is aware of. The statement that there are hundreds of permanently empty beds in the poor-law infirmaries was not, as he assumes, my own invention, but was reproduced from a recent speech made by the Minister of Health, whom Dr. Muir can hardly charge as he charges me with knowing nothing about the subject. Perhaps Dr. Muir would not have been quite so derisive of this statement had he recognised its origin.

I accepted Dr. Muir's possibly exaggerated estimate of the waiting-lists at voluntary hospitals out of compliment to him, and because the congestion which he described supported my argument as to the relative popularity with patients of the voluntary hospitals as compared with other institutions. The voluntary hospitals would welcome some relief from this congestion, and I am in agreement with Dr. Muir in thinking that when the poor-law hospitals come under the new management proposed for them and secure an improved personnel, and consequently an improvement of prestige, they will go some way towards solving the problem of dealing with redundant patients. But I was describing things as they are and not as they promise to be. In this connexion the letter which immediately follows Dr. Muir's in your issue of the 28th ult. amply corroborates my picture of the poor-law institution of the present day. Dr. Muir overlooks the very pertinent circumstance which I pointed out in my address, that the voluntary hospitals are in fact expanding with somewhat remarkable rapidity to meet the demands made upon them. In London alone in 1924 1600 beds were added to those hospitals which come under the King's Fund, and another 1200 beds in 1926, and expansion is continually in progress at nearly all the voluntary hospitals in London.

I am a medical man in full hospital and private practice who happens also to be a Member of Parliament, and I have tried as far as I have been able to act as a "Member for Medicine," which is very inadequately represented in the House of Commons. If Dr. Muir chooses to call me a politician I do not mind, but I suspect him of choosing this appellation in order to accuse me of a lack of political sagacity because I described with Mr. Spencer a system of voluntary management of hospitals in London which does not suit Dr. Muir. I am content to pit against Dr. Muir's political insight and knowledge the political insight and knowledge of the leader writer in the *Times* of Jan. 11th, who, commenting on this scheme suggested by Mr. Spencer and myself, wrote so favourably of it.—I am, Sir, yours faithfully,

Feb. 6th, 1928. E. GRAHAM LITTLE.

RECURRENT COLDS.

To the Editor of THE LANCET.

SIR,—The correspondence in your issue of Dec. 31st, 1927, on this undignified indisposition will prove exceedingly helpful. Recently, however, I have been able to dispense with many of the usual efforts, including what Dr. Graham-Stewart designates the religious use of the spray. I sacrilegiously (I will not say irreligiously) employ one of the symmetrical ureas as advocated by his neighbour, Mr. J. E. R. McDonagh. Exit the sneeze.

I am, Sir, yours faithfully,

Calif., U.S.A., Jan. 18th, 1928. A. L. GRANT.

TREATMENT OF THE MALARIAS.

To the Editor of THE LANCET.

SIR,—Referring to Dr. Carmichael Low's letter in your last issue the difficulty in the treatment of subtertian malaria up to the present time has been the elimination of the crescent from the body. The fact is that there is no known drug which destroys the crescents so effectively and in so short a time as does plasmochin and plasmochin-compound. This is the main point which has been substantiated by a number of workers. As it has been shown that quinine acts directly upon the schizonts of the subtertian parasite and plasmochin upon the crescents, the combination of these two drugs, in Dr. Low's own words, "will act better than either given alone." Dr. Low's parallel between the goose, golden eggs, and the affinity of quinine for the immature stages of the crescent in the blood stream is, in the present state of our knowledge, an incomplete ornithological simile. With further experience of plasmochin-compound and comparison of control cases Dr. Low will, I trust, see reasons for amending his rather pessimistic attitude to what may prove to be a distinct therapeutic advance in the treatment of a particularly intractable malady.—I am, Sir, yours faithfully,

Feb. 6th. PHILIP MANSON-BAHR, M.D., F.R.C.P.

"FRIGHT DISEASE."

To the Editor of THE LANCET.

SIR,—In your annotation on this condition in dogs, a certain measure of scientific caution is most properly apparent. Nor am I ignorant of what class step in where angels fear to tread. Nevertheless, I would venture to take exception to the statement that "so far as can be judged, the disease seems to be peculiar to dogs . . . nothing identical has been observed in any other species of domesticated animal." Amongst the domesticated animals man himself takes the place of honour, and should not be excluded from the survey. It is true that he does not on small provocation rush about and dash himself against trees—although even of that a typical record may be found in the works of Lafcadio Hearne. But this rushing about, this excessive freedom, cannot be the whole disease. It is known to be infectious to a high degree, and those who look closely enough may often chance on prodromata and sequelæ. Only this day have I seen a valuable dog dying of what in a human being we should call encephalitis lethargica. A week or two ago he had typical fright symptoms and shortly before that a febrile attack. Also, it is well known that in a large kennel affected with encephalitis there are often some cases of the fright disease.

This encephalitis in dogs has been very frequent of late, and a year ago in this district there was a case in which not only the canine members of a domestic circle, but two of the adults, were affected with similar symptoms. All died quickly, except one, who developed Parkinsonism. Such instances, even if isolated and atypical, give one furiously to think. I would at least plead that this fright disease be regarded as possibly only a very small part of a much more serious picture, a picture from which man himself is not excluded.

I am, Sir, yours faithfully,

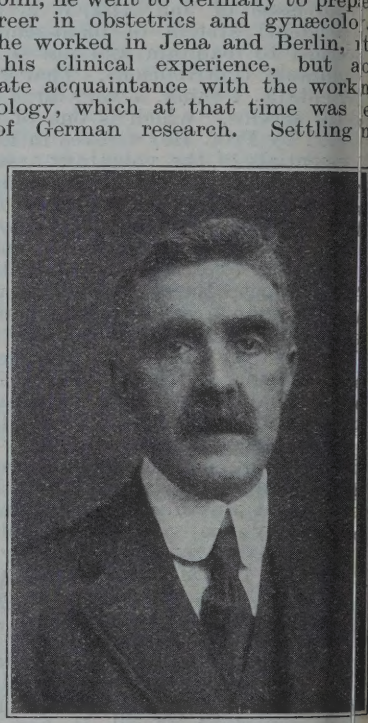
Sevenoaks, Kent, Feb. 3rd, 1928. GORDON WARD.

Obituary.

GEORGE BALFOUR MARSHALL, M.D. EDIN. F.R.F.P.S. GLASG.

WE regret to record the death of Prof. Balfo Marshall, consulting gynæcologist to the Glasg Royal Infirmary, which occurred on Jan. 31st, a nursing home in Glasgow, in the sixty-fifth year his age.

George Balfour Marshall was born on June 17 1863, in Edinburgh, where his family had play for very many years, an important part in busin and municipal affairs. After a distinguished und graduate career in the University, a term of duty house surgeon in the Royal Maternity Hospital the and a spell in Dublin, he went to Germany to prep himself for a career in obstetrics and gynæcolo For three years he worked in Jena and Berlin, only extending his clinical experience, but a gaining an intimate acquaintance with the work pathological histology, which at that time was favourite field of German research. Settling Glasgow in 1893, he commenced practice in his specialty, graduated M.D. of Edinburgh, and was admitted a Fellow of the Royal Faculty of Physicians and Surgeons, Glasgow, in the following year. He became attached to the gynæcological staff of Glasgow Royal Infirmary, and, eventually, in 1907, was appointed to the charge of the wards vacated by the late Dr. Kelly. He continued to give loyal and valuable service to the Infirmary until his retirement in 1923. His hospital association brought him into close con with the Extra-Mural Medical School in Glasg and he was one of its most popular teach for years his classroom in the old Western Med School at the University Gate was crowded w enthusiastic students. This experience he to refer to as one of the happiest of his memo For many years he lectured in gynæcology St. Mungo's College, and on the retiral of Dr. Ro Jardine in 1921, was appointed to the Chair Midwifery there. He was a most attractive lectu vigorous in expressing his opinions to students, always ready with a pawky wit to stimulate the lagg or silence the boisterous. His lectures in the Wes Medical School formed the basis of the excel "Manual of Obstetrics," which he published in 1 Indeed, to the literature of his subject he made m contributions, characterised by careful observa and sound judgment. Accuracy and restraint the special features of all his work, written or formed.



PROF. BALFOUR MARSHALL.

Photograph by T. & R. Annan, Gl

The family tradition of public service was ca on by Dr. Marshall in many directions. He wo valiantly to establish and consolidate the Me and Dental Defence Union of Scotland, and was of its most trusted councillors. For several y

represented the Royal Faculty of Physicians and rgeons on the directorate of the Glasgow Royal aternity and Women's Hospital, to the acceptance ike of patients, students, and staff. He was a ithful supporter of the local Obstetrical and Gynæcoical Society and graduated through all its offices the presidency. He was appointed by the Privy uncil to be the Government visitor under the rmacy Act, and it was characteristic of the man at, though this work was so far removed from his rn, he took pains to master every detail of it. careful surgeon, no detail was too trifling for his tention, and his theatre work was a demonstration calm dexterity. His widespread interests made him delightful companion, and his caustic wit added zest to his conversation. A loyal friend and helpful lleague, he was always ready to advise and courage his juniors. To all he was the embodiment courtesy, and he was one of the most modest of en. He had a great love for his country, and rticularly for the north-west Highlands, where was able not only to gratify his cult of the d and the fly, but to secure the camera films which spent the winter in perfecting. So recently as st autumn he won a first prize at one of the great hibitions of photography.

For several years Dr. Marshall had suffered from tarrhal chest conditions; while he coughed, he uld declare that no Edinburgh man could stand e sooty atmosphere of Glasgow. Recently he d been less fit than usual, but he carried on his ties bravely, and ten days before his death lectured th his usual sparkle to his class at St. Mungo's llege. On the following day he was taken ill ddenly, and was operated upon on the same afterion for an intestinal perforation; but a more sperate lesion was found lower in the bowel, and passed peacefully away on the morning of n. 31st. He had lived a full and useful life, and s death will be deeply felt not only by the medical cognised his worth. Last year Dr. Marshall ofession, but by the whole city, whose inhabitants lebrated his silver wedding, and he leaves a widow d three children.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS ENGLAND.—At the Final Examination of the Conjoint ard held from Jan. 10th to 31st the following candidates re approved in the undermentioned subjects, but are not gible for diplomas:—

Medicine.—R. E. Artrick, Univ. Coll.; Mabel A. Baker, Royal Free; G. N. Beeston, Charing Cross; S. Behrman, St. Bart.'s; S. P. Bhatia, St. Thomas's; C. H. Birt, Birmingham; J. R. Bond, Univ. Coll.; M. T. Brockman, Guy's; Nellie Brown, Westminster; J. M. Buchanan, Melbourne and Middlesex; G. Campbell, St. Thomas's; T. H. Carr, Leeds; J. E. Crooks, Guy's; H. S. Davies, King's Coll.; P. Dickman, Charing Cross; R. C. Dracup, Bombay and St. Thomas's; C. Emery, Univ. Coll.; Marguerite M. Fenn, Royal Free; Cecilia F. Fox, Bristol; H. N. W. Harley, Guy's; Kathleen M. Henderson, Royal Free; J. S. Hensman, Cambridge and St. Bart.'s; H. P. Himsworth, Univ. Coll.; A. N. Hobbs, St. Bart.'s; S. D. Isaacs, Cambridge and Birmingham; Florence H. Johnson, Oxford and Univ. Coll.; Olive M. G. Jones and Emma J. King, Royal Free; L. H. Lerman, Middlesex; Marjorie H. Lester, Royal Free; G. W. T. McDonnell, London; G. D. Malhoutra, Punjab and St. Thomas's; Mary L. Marsh, Charing Cross; C. G. Millman, King's Coll.; N. S. Narasimhan, Guy's; C. W. Olsen, Michigan and St. Bart.'s; R. L. Peregrine, Oxford and Guy's; R. J. H. Raines, Leeds; Edith M. Redding, Charing Cross; A. Shedrow, Paris and St. Bart.'s; Thelma Shepherd, Royal Free; H. N. Skelton, Sheffield; Edith J. L. Smith, Royal Free; E. J. J. Smith, St. Bart.'s; M. Sternfeld, Freiburg; D. M. Sivasubrahmaniam, Madras and London; W. H. S. Wallace, St. Thomas's; D. B. J. Wijeyesekera, Ceylon; B. Williams, Edinburgh; J. C. F. L. Williamson, Cambridge and St. Bart.'s; J. M. Wrigley, London; and Janet D. E. Young, Lausanne and Royal Free.

Surgery.—B. A. J. Arthure, Charing Cross; Ellen M. Barnes, Univ. Coll.; N. R. Barrett, St. Thomas's; S. Behrman, St. Bart.'s; A. D. C. Bell, St. Thomas's; H. H. Boyden, St. Bart.'s; E. C. B. Butler and E. N. Callum, London; A. G. Carmichael, Middlesex; B. R. Caygill, Leeds; B. Cimbelmann, Basel and Middlesex; E. Corner, London; O. J. C. Cotton, St. Thomas's; A. Dala, Liverpool; W. J. G. Drake-Lee, St. Thomas's; G. H. Gange, Cambridge and Middlesex; G. H. Garfield, Cardiff; S. L. Gargye, Manchester; P. S. Gitlin, Guy's; F. N. Goggs, St. George's; S. Goldman, London; Helen M. Herbert, Royal Free; H. P. Himsworth, Univ. Coll.; R. Hodkinson, St. George's; P. E. G. Hopkins, Guy's; Kathleen Horne, Leeds; J. G. H. Ince, Univ. Coll.; A. W. Johns, London; G. R. Jones, Cambridge and King's Coll.; Margaret L. Jones, Univ. Coll.; G. H. Kennett, Sydney; L. B. Langmead, Guy's; E. G. Laurence, St. Bart.'s; L. H. Lerman, Middlesex; I. B. Limbery, St. Thomas's; F. W. Linton-Bogle and G. C. C. MacVicker, St. Bart.'s; F. B. Mallinson, St. George's; J. I. Mathias, Univ. Coll.; Oonnunniamma Matthai, Madras and Royal Free; I. Morris, Univ. Coll.; L. H. Morris, London; J. E. Morton, Guy's; L. J. O'Loughlin, Manchester; E. A. E. Palmer, St. Bart.'s; D. N. Parfitt, Cardiff; L. S. Penrose, Cambridge and St. Thomas's; F. Phillips, Adelaide; R. E. M. Pilcher, St. Thomas's; N. E. Pitt, Guy's; N. L. Probert and A. Rabinowitz, Middlesex; Elsie E. A. Ridley, Royal Free; R. E. Rix, Guy's; R. W. N. Robins, St. Thomas's; K. T. Samatapala, King's Coll.; H. R. D. Schofield, St. Mary's; F. G. V. Scovell, St. Bart.'s; E. H. Sears, Guy's; H. M. Sein, Calcutta and Guy's; R. Shelley and W. H. Simonds, St. Thomas's; Constance B. Smith, King's Coll.; T. R. Smith, J. E. Snow, and H. Stevens, St. Bart.'s; B. Stewart, Cambridge and Leeds; H. H. Stewart, St. Thomas's; R. Ström-Olsen, Cardiff; J. Vaughan-Bradley, Cambridge and St. Thomas's; F. H. Ward, St. Bart.'s; H. G. Wells, Westminster; Editha A. S. Wharton, Royal Free; Gladys E. Wilkinson, Manchester; F. Williams, Cambridge and London; T. P. Williams, St. Bart.'s; T. G. Willis, London; H. S. H. Wood, Middlesex; Evelyn C. Woodhead, Guy's; and R. G. Zaglama, Manchester.

Midwifery.—Constance E. Allen, Charing Cross; V. E. N. Allen, Bristol; I. T. Barling, N. R. Barrett, A. D. C. Bell, and S. P. Bhatia, St. Thomas's; K. C. Bhattacharyya, Durham; C. H. Birt, Birmingham; F. A. Blackwood, St. Thomas's; K. C. Blyth, London; V. G. Borgaonkar, Bombay; B. J. Bouché, Guy's; J. M. Buchanan, Melbourne and Middlesex; A. G. Carmichael, Middlesex; Nellie Clifton and Dorothy M. Conyers, Royal Free; T. M. Corcoran, Univ. Coll.; T. C. Dance, Birmingham; E. C. Dayus, St. Mary's; C. G. S. De Silva, Guy's; Marjorie M. Dobson, Royal Free; R. M. Dowdeswell, Cambridge and St. Thomas's; W. J. G. Drake-Lee, St. Thomas's; E. C. Duffett, Guy's; C. Emery, Univ. Coll.; E. V. Frederick, St. Bart.'s; M. A. Gaffar, Durham; G. H. Gange, Cambridge and Middlesex; I. K. Gayid, Cairo; W. N. O. George, Univ. Coll.; R. Gilmore, Manchester; P. S. Gitlin, Guy's; A. Hamid, Middlesex; H. S. Hamlin, St. Thomas's; A. El-S Handousa, G. A. S. Harris, and M. R. W. Hart, St. Bart.'s; H. P. Himsworth, Univ. Coll.; R. Hodkinson, St. George's; B. Hoffenberg, Liverpool; L. Hoffman, St. Bart.'s; C. E. Holden, Cambridge and St. Bart.'s; J. H. Hopper, St. Thomas's; E. J. Horn, London; M. C. Hounsfield, Cambridge and St. Bart.'s; I. M. Hughes, Manchester; Effie L. Hutton, Royal Free; C. F. Ind, Durham; R. A. Isenstein, Adelaide and London; L. A. Jacob, St. Thomas's; M. Jafar, Punjab; S. K. Jatar and E. J. Javeri, Bombay; L. A. Joelson and A. W. Johns, London; R. V. Kalyanpurker, Bombay; S. Paul and N. F. Kendall, St. Bart.'s; H. Y. Khwaja, Bombay; G. G. King, St. Mary's; T. C. Kohler, Adelaide and London; L. B. Langmead, Guy's; J. Lieberman, Leeds; K. Lindberg, Paris and London; F. W. Linton-Bogle, St. Bart.'s; O. T. Lloyd, Westminster; R. M. B. Lowis, St. Thomas's; M. Luckeenarain, Univ. Coll.; A. Maberly, St. Thomas's; G. C. C. MacVicker and M. J. Malley, St. Bart.'s; W. E. Mashiter, Cambridge and St. Thomas's; Olive S. May, King's Coll.; H. C. Mehta, Lahore; K. G. Milad, St. Mary's; G. Na Ranong, St. Thomas's; L. A. Newton, St. Bart.'s; D. A. Nicoll, King's Coll.; J. P. O'Donnell, Leeds; C. W. Olsen, Michigan and St. Bart.'s; M. K. Omar, Birmingham; D. N. Parfitt, Cardiff; L. S. Penrose, Cambridge and St. Thomas's; Alice D. K. Peters, Charing Cross; E. R. S. Phillips, London; F. Phillips, Adelaide; N. E. Pitt, Guy's; T. R. Plummer, St. George's; F. Pomarantz, St. Bart.'s; H. G. Pritchard, Charing Cross; S. M. Rahman, Middlesex; R. H. Raine, Durham; R. J. H. Raines, Leeds; M. H. Rashwan, Guy's; E. G. Recordon, St. Bart.'s; A. Reichlin, Leeds; J. B. A. Reynolds, St. Bart.'s; R. W. N. Robins, St. Thomas's; Eluned Saunders, Westminster; N. Schachnowitsch, Berlin and London; C. P. Scott, St. Thomas's; G. M. A. Shaikh, Bombay; D. M. Sivasubrahmaniam and D. R. E. Smith, London; E. J. J. Smith, St. Bart.'s; C. E. Soodeen, Middlesex; D. Stephens and H. Stevens, St. Bart.'s; H. H. Stewart, St. Thomas's; G. S. Storrs, Cambridge and St. Thomas's; R. Ström-Olsen, Cardiff; K. G. Sugden, St. Bart.'s; E. E. Swaby, Westminster; J. M. Taylor, St. Bart.'s; P. R. Thambugaga, Middlesex; A. R. Thomas, St. George's; Phyllis D. Towell, Royal Free; B. T. Utley, St. George's; Ercenwin A. Utting, St. Mary's; V. C. Verbi, King's Coll.; A. R. Waterhouse, Leeds; Grace E. Watson, Royal Free; T. G. Willis, London; A. Wilson, Leeds; and Janet D. E. Young, Lausanne and Royal Free.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following is a supplementary list of 57 Licentiates issued recently by the College as the result of the Final Examination which terminated on Jan. 31st:—

G. J. Ahern, N.U.I. and London; A. F. Alsop, St. Bart.'s; Katherine Barnett, Charing Cross; A. L. Basham, St. Thomas's; H. L. W. Beach, St. Bart.'s; V. C. Benson, Cambridge and Guy's; Olwen R. Binyon, St. Mary's; L. Blackstone, London; E. W. Bowskill, Manchester and

Charing Cross; Joan C. Clatworthy, Univ. Coll.; E. C. Cosgrove, Cambridge and St. Bart.'s; C. F. J. Cropper, Oxford and King's Coll.; J. H. Cullinan, Cape, Edinburgh, and Guy's; J. L. H. Easton, Cambridge and King's Coll.; El S. El H. El Zawahry, Cairo and Middlesex; C. W. Evans, St. Mary's; G. H. Evans, Cambridge and London; M. J. Evans, St. Bart.'s; R. Evans, Univ. Coll.; J. C. Fast, Guy's; J. D. S. Flew, Univ. Coll.; H. W. Frickel, Cape and St. Mary's; Christina Gibson, King's Coll; J. C. Gregory, Univ. Coll.; M. M. Gyi, St. Thomas's; H. N. Hallam, Cambridge and London; D. G. Hamilton, St. Thomas's; E. R. Holiday, Oxford and London; Agnes H. Jackson, King's Coll.; Nigel M. Jerram, Cambridge and St. Thomas's; P. D. Johnson, St. Thomas's; R. A. Kennedy, Cambridge and St. Thomas's; M. Koettlitz, Cambridge and St. Thomas's; A. H. Lafone, St. Mary's; L. P. E. Laurent, Univ. Coll.; Margaret Leathes, Cambridge and Royal Free; K. Lindenbaum, St. Mary's; R. F. Lister, Cambridge and London; Janet Lochore, Royal Free and Edinburgh: J. V. Macgregor, Univ. Coll.; W. A. N. Marrow, Middlesex; D. B. Mumby, St. Thomas's; M. T. O'Sullivan, Cork and Guy's; Gwynedd M. Phillips, King's Coll.; R. W. Raven, St. Bart.'s; R. W. Reid, St. Thomas's; I. Schoub, Petrograd and London; Margaret P. Shackle, Cambridge and King's Coll.; C. G. Sinclair, St. Bart.'s; . AB. Swarbreck, South Africa and Univ. Coll.; H. M. Turnbull, Durham and Charing Cross; K. R. Unger, Middlesex; R. N. Wilcox, St. Thomas's; C. E. Willing, Adelaide; G. N. Wood, Cambridge and Guy's; C. Wroth, St. Bart.'s; and B. A. Young, Univ. Coll.

UNIVERSITY OF LONDON.—The degree of D.Sc. in biochemistry has been conferred on Mr. H. G. Reeves, of King's College. The degree of Ph.D. in bacteriology has been conferred on Mr. F. M. Burnet, of the Lister Institute, and the same degree in the principles, history, and method of science on Miss D. M. Turner, of University College. At the same examination Mr. G. D. Morison, of the North of Scotland College of Agriculture, obtained the degree of Ph.D. in entomology.

MEDICAL SOCIETY OF LONDON.—The 155th anniversary dinner will be held at the Trocadero Restaurant, Shaftesbury-avenue, W.C., on Thursday, March 8th, at 7.45 P.M. Mr. H. W. Carson, the President, will be in the chair.

ROYAL MICROSCOPICAL SOCIETY.—A meeting will be held at 20, Hanover-square, W. 1, on Feb. 15th, at 7.30 P.M., when Mr. D. J. Scurfield will read a paper on A New Type of Aquarium Microscope, and Prof. J. T. Wilson will describe a convenient table for microscopy.

INDUSTRIAL MEDICINE.—As already announced, the fifth International Medical Congress for Industrial Accidents and Diseases will be held in Budapest from Sept. 2nd–8th, and the Council of Industrial Medicine has been nominated to act as the British National Committee. Dr. D. A. Coles, chairman of the Council, and Prof. Edgar L. Collis, vice-chairman, along with Sir Thomas Oliver and Dr. Theodore Thompson, are the members of the Permanent Committee of the Congress. It is hoped that a large number of medical men and women in this country who are interested in the problems of industrial disease will attend a congress which promises to be a great scientific and social event. Further information can be had from the Secretary of the Council or from the hon. foreign secretary, Dr. H. S. N. Menko, 12, Stratford-place, London, W. 1.

TAVISTOCK CLINIC FESTIVAL DINNER.—A dinner to commemorate the clinic's seventh "birthday," was held on Feb. 6th at the Mayfair Hotel, under the chairmanship of Mr. Dougal O. Malcolm, the treasurer, who proposed the health of the visitors. He explained the work and financial difficulties of the clinic, and appealed for a substantial birthday gift from the "grown-ups" present. Viscount Lascelles, responding, wittily described the plight of the mill-owners of the West Riding since skirts became short, and urged that every penny saved on dress materials should be given to the clinic, which was doing a work of great importance to the nation's mental health. Manifestations of nervous disorder ranged, he had been told, from insanity to asthma and from paralysis to eczema, and the country looked to such institutions as the Tavistock Clinic to repair the nervous system of the parents of the next generation. Sir Farquhar Buzzard, proposing "The Clinic," said that the education of the "normal" population was one of the great problems of the future. Reform in education could only come about, as in medicine, through a study of the symptoms and ætiology of bad results. Psychotherapy revealed the difficulties of the child and youth in process of education. The company had heard enough of the work of the Tavistock Clinic to arouse a strong desire to give to it. He himself would give a piece of gratuitous advice of a professional character; they must not suppress their desire. Dr. H. Crichton Miller, replying, paid a tribute to the work of the staff and claimed personal credit only for introducing the psycho-analytical farce "Suppressed Desires," which was then played. Lord Lascelles announced that annual subscriptions to the amount of £162 11*s.* and gifts to the amount of £375 8*s.* 6*d.* had been promised that evening.

UNIVERSITY OF MANCHESTER.—Sir Arthur Keith will deliver a Ludwig Mond lecture on May 8th at the University on Implications of Darwinism.

LISTERIAN SOCIETY.—Mr. N. D. Buxton will give the presidential address at King's College Hospital on Feb. 15th at 8 P.M. As this is the bicentenary year of the birth of John Hunter the subject of the address will be Hunter's Life and Work.

RESEARCH IN SANITARY SCIENCE.—The next election to the Grocers' Company Research Scholarships in sanitary science will take place in May. Each scholarship is of the value of £300 a year with an allowance for cost of apparatus and other working expenses. The scholarships are renewable for a second or third year.

A MOTOR CLUB'S INSURANCE SCHEME.—An insurance scheme has been established by the Middlesbrough Motor Club to enable hospitals, in any part of the country, to receive payment for treating members injured in road accidents. Members will pay a premium of 2*s.* 6*d.*, and the following scale of payments to hospitals has been fixed: single dressing, 10*s.* 6*d.*; one day's detention, £1 1*s.*; one week, £3; and at the same rate up to five or six weeks.

LONDON HOSPITAL SUNDAY FUND.—Mr. R. Holland Martin, C.B., has been re-elected Vice-President, Sir Charles Wakefield and Mr. John Henry Buxton hon. secretaries, and Mr. J. Arnold James secretary. Mr. A. L. Sturge, formerly chairman of Lloyd's, and the Rev. A. A. Green, of the Hampstead Synagogue, have been added to the General Purposes Committee.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—The next quarterly meeting of this association will take place on Thursday, Feb. 16th, at City Mental Hospital, Fishponds, Bristol. On Wednesday, Feb. 15th, at 7.30, P.M. there will be a dinner at the Royal Hotel, College Green. A paper entitled Some Points in the Histology of the Globus Pallidus will be read by Dr. E. Barton White and Dr. Geoffrey Hadfield, and will be followed by a paper entitled Some Notes on the Mental State in Cardiac Disease, by Dr. Carey Coombs.

ROYAL FREE HOSPITAL.—A Centenary service of thanksgiving will be held at St. Andrew's, Holborn, on Sunday, Feb. 19th, at 11 A.M., when the preacher will be the Bishop of Willesden, and the Lord Mayor and the Mayor of Holborn, Finsbury, and Islington will be present in state. Places will be reserved for those who notify the secretary of their intention to attend. St. Andrew's has been chosen for the reason that the foundation of the hospital came about through an incident which happened in the precincts of the church and is commemorated by a memorial tablet in the nave.

THE Ella Sachs Plotz Foundation has now made 55 grants for the advancement of scientific investigation and has aided workers in the United States, Great Britain, France, Germany, Austria, Hungary, Switzerland, Italy, Sweden, Esthonia, and Czecho-Slovakia. During 1927 17 new grants were made to scientists outside the United States. The only British recipient last year was Dr. J. Dawson, of Edinburgh, who is investigating the pathology of the breast. Applications for 1928–29 should be in the hands of Dr. Joseph C. Aub, Massachusetts General Hospital, Boston, before May 15th.

Messrs. J. and A. Churchill announce the early publication of the following books: A ninth edition of Lee's "Microtomist's Vade Mecum," edited by Dr. J. Brontë Gatenby and Dr. E. V. Cowdry, with collaborators; "Oils, Fats, and Fatty Foods," by E. Richards Bolton; second and enlarged edition of the work originally called "Fatty Foods," by Bolton and Revis. "Laboratory Manual for the Detection of Poisons and Powerful Drugs," by Dr. W. Autenrieth, translated from the fifth German edition. A new volume entitled "An Elementary Text-Book of General Microbiology," by W. Giltner.

ROYAL SANITARY INSTITUTE.—The annual congress is being arranged at Plymouth from July 16th–21st under the presidency of Lord Astor, at which the usual sectional meetings will be held for the reading and discussion of papers relating to Sanitary Science and Preventive Medicine, Maternity and Child Welfare including School Hygiene, Personal and Domestic Hygiene, Hygiene of Food, Hygiene in Industry, and Veterinary Hygiene. Conferences of various groups of public health officers are planned and a popular lecture will be given by Prof. W. E. Dixon. During the congress an exhibition of municipal sanitation and appliances relating to domestic health and comfort will be opened. Anyone wishing to take part should address the Secretary of the Institute at 90, Buckingham Palace-road, London, S.W. 1.

DONATIONS AND BEQUESTS.—Mr. Joseph Hall, of rton Lees, Sheffield, left £50,000 for charity, including 5,000 to his sister-in-law, Clara Ann Hall, at her absolute posal to apply all or part thereof for such charitable rposes as are known to have been the intention of his late ther, and £500 each to the Sheffield Institution for the nd, Sheffield Royal Infirmary, Sheffield Royal Hospital, e Jessop Hospital for Women, the Free Hospital for Sick ildren, Sheffield, and the Rotherham Hospital and spensary.—Mrs. Maria Draycott-Smith, Nottingham, left 0 to the Nottingham Cripples Guild Fund, £200 each the Royal Midland Institute for the Blind and the ttingham Midland Eye Infirmary, and after a few other acies, the residue of her property to Nottingham General spital and the Castle Gate Samaritan Hospital for Women, ttingham, in equal shares.—Apart from the payment of ne private bequests the whole fortune amounting to 0,000 of Mr. James Sanderson, of The Hawthorns, lashiels, Selkirkshire, woollen manufacturer, has been left charity. He left besides other bequests £1000 each to the ttage Hospital, Galashiels, and the Queen Victoria bilee Nurses Fund. The residue of the property is to be ided into 22 parts and as to 18 for, amongst others, for erection and endowment of cottage homes for the erving poor of Galashiels, five to the University of inburgh for certain specified purposes, one part each to inburgh Infirmary and the Royal Edinburgh spital for Incurables, one-half part to the Royal inburgh Hospital for Sick Children, and one-quarter part h to the Royal Blind Asylum and School Edinburgh and Royal Society for Home Relief for Incurables, Edinburgh.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

OPENING OF PARLIAMENT: THE KING'S SPEECH.

THE new session of Parliament was opened by the King State on Tuesday, Feb. 7th. In the course of the Speech m the Throne His Majesty said that measures would be sented during the coming session for giving effect to tain recommendations of the Royal Commission on tional Health Insurance. The burdens imposed upon ustry and agriculture by the present incidence of local es had attracted the anxious attention of the Government, o were now engaged upon inquiries into the possibility affording some relief from these burdens to the producing mmunity and into the changes in local government which uld thereby be involved.

FRANCHISE BILL.

On Tuesday, Feb. 7th, Sir W. JOYNSON-HICKS (Home retary) gave notice of his intention to bring in a Bill amend the law relating to the Parliamentary and local vernment franchise.

HOUSE OF LORDS.

TUESDAY, FEB. 7TH.

DEBATE ON THE ADDRESS.

The motion for a humble address of thanks to His jesty for his gracious Speech was moved by the DUKE OF NTROSE and seconded by Lord CRANWORTH.

The MARQUESS OF SALISBURY (Lord Privy Seal), speaking behalf of the Government, and replying to certain icisms made by Viscount HALDANE (Leader of the position peers), Earl BEAUCHAMP (Leader of the Liberal ers), and others, said that owing to the shortness of the sent session, due to the fact that the Government hoped prorogue Parliament at the end of the summer and begin new session in November, the Government would not ceed with the Factories Bill at present. Their lordships st not think, however, that the Government had andoned that Bill. They hoped that it would be one of measures—perhaps the principal one—which would eive a second reading before next Christmas in the next sion.

The Address was agreed to.

HOUSE OF COMMONS.

TUESDAY, FEB. 7TH.

The SPEAKER, having read the King's Speech,

Colonel LAMBERT WARD moved a humble address of nks to His Majesty for his gracious Speech.

Mr. TEMPLETON seconded.

Mr. RAMSAY MACDONALD (Leader of the Opposition) said that this was the most meagre King's Speech he had ever heard read during his time in the House. The Government's idea of this session apparently was that it was going to be pretty much of a prolonged holiday so far as they were concerned. Well, they would have to see about that, because the Opposition did not take the same complacent view of social conditions as was taken by those who had drafted this speech for His Majesty. With regard to the domestic programme outlined by the Government in the King's Speech the most prominent feature was it omissions. There was, for instance, the Factory Bill which had been promised over and over again. There was also the Washington Convention. The Government's economic policy from beginning to end had been that the nation's trade was to be built up on low wages, sweated conditions, and long hours.

Mr. LLOYD GEORGE, referring to the promised National Health Insurance Bill, said he assumed that it would deal with the recommendations of the Royal Commission which reported about a couple of years ago, and which was appointed by the late Minister of Health.

Mr. CHAMBERLAIN (Minister of Health) indicated assent.

Mr. LLOYD GEORGE: I should like to know whether there is any cash in that. Is the Chancellor of the Exchequer going to pay back the money which he extracted?

Mr. CHURCHILL shook his head.

Mr. LLOYD GEORGE: Then I can tell him that unless he does so those recommendations will be of no use at all. They will be like an engine without petrol; they will not march, they will stick. The only recommendations of the slightest value in that Commission's report are in regard to additional benefits. Some of those recommendations are invaluable, but they all mean more cash, and I do not believe that that cash is available now. Can the Minister of Health get the money back which the Chancellor of the Exchequer has taken away? The Chancellor of the Exchequer has shaken his head very emphatically. I am afraid that he is going to win on this occasion, and I do not look forward to this Bill with any sort of satisfaction; nor will anybody else.

Mr. BALDWIN (Prime Minister), who spoke immediately after Mr. Lloyd George, said that he was not sure if the right hon. gentlemen asked if there was any "catch" or any "cash" in the proposed Health Insurance Bill.

Mr. LLOYD GEORGE said that he used the word "cash."

Mr. BALDWIN: There is neither "cash" nor a "catch" in the Bill. I am told that it deals purely with machinery, which will facilitate very much the working of the Act, and it will neither cost the Exchequer anything nor bring anything into their funds. Continuing, Mr. Baldwin said that the Government hoped to have an autumn session. The Government regretted very much that in the circumstances there was no possibility of getting through any Bill which might be regarded as controversial between now and the end of July. He hoped, if they were able to begin a new session as they intended in November, that the Factories Bill might be dealt with before the end of the next session.

The debate on the Address was adjourned.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Feb. 13th.—5 P.M., WAR. Paper: Surgeon-Commander S. F. Dudley, R.N.: Some Aspects of the Epidemiology of Typhoid Fever in the Royal Navy.

TUESDAY.—4.30 P.M., PSYCHIATRY. Clinical Meeting at the Maudsley Hospital, Denmark Hill, S.E. Tea will be provided at 4 P.M. A series of cases of acute schizophrenia will be shown. A discussion on prognosis in acute schizophrenia will follow. Visitors will have an opportunity of inspecting various pathological specimens.

WEDNESDAY.—LIBRARY. The main Library will close at 5 P.M., but readers will be accommodated in other rooms until 6.30 P.M. 8.30 P.M., SOCIAL EVENING. From 8.30 to 9 P.M. Fellows and guests will be received in the Library by the President and Lady Berry. At 9.15 P.M. Lieut.-Colonel W. P. MacArthur, R.A.M.C., will give an Address entitled Some Medical References in Pepys (with illustrations). The Library will be open, and a number of exhibits, kindly lent by the Wellcome Historical Medical Museum, and others will be on view. Music and light refreshments.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.). Cases: Dr. H. MacCormac: (1) Leukæmic Erythro-

dermia. Dr. M. Sydney Thomson: (2) Acanthosis Nigricans. Other cases will be shown.

FRIDAY.—8 P.M., OBSTETRICS. Specimen: Dr. Bethel Solomons: Two Uteri removed for Puerperal Sepsis. Short Communication: Mr. J. Ellison: Two Extreme Cases of Multiple Myomata in Sisters of under 25 Years. Paper: Mr. Frederick Roques: Encephalitis Lethargica and Pregnancy. 8.30 P.M., ELECTRO-THERAPEUTICS. Cinematograph Demonstration: Dr. R. G. Canti: Tissue Cultures, including the Action of Irradiation on Living Cells Grown in vitro.

MEDICAL SOCIETY OF LONDON, 11, Cavendish-street, W.

MONDAY, Feb. 13th.—8.30 P.M., Discussion on the Use and Abuse of Ultra-violet Light Therapy, to be introduced by Dr. Leonard Hill, Dr. O'Donovan, and Dr. C. B. Heald.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.

SATURDAY, Feb. 18th.—3 P.M. (at 122, Harley-street, W.), adjourned meeting, Dr. A. Niven: Open-air Treatment and Meteorological Conditions

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, London, W.

THURSDAY, Feb. 16th.—8.15 P.M., preceded by a demonstration at 7.45 P.M., Dr. A. R. Paterson: The Provision of Medical and Sanitary Services Among Rural Populations in Tropical Africa.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, Feb. 13th.—Demonstrations in the morning and afternoon by the Conservator and the Librarian.

TUESDAY.—4 P.M., Sir Holburt Waring: Hunterian Oration on the Progress of Surgery from Hunter's Day to Ours. Demonstrations morning and afternoon by the Conservator and Librarian. Festival Dinner, 8 P.M.

WEDNESDAY.—Demonstrations morning and afternoon.

THURSDAY.—Demonstrations in morning only. 3 P.M., Reception at the College. 5 P.M., Dr. G. C. Peachey: Thomas Vicary Lecture on the Homes of the Hunters.

FRIDAY.—Demonstrations.

SATURDAY.—Demonstrations.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 13th, to SATURDAY, Feb. 18th.—FELLOWSHIP OF MEDICINE LECTURE at the Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., at 5 P.M., Mr. Duncan Fitzwilliams: Hysterical Breasts.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Mon., clinical demonstrations by Dr. C. Worster-Drought, at 5 P.M.—ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, W.C. Fri., clinical demonstrations by Mr. Alban Andrews, at 5 P.M.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross, W.C. Fri., lecture-demonstration by Mr. M. L. Hine on the Clinical Application of Perimetry, at 5 P.M. The above are open to members of the medical profession, without fee.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Course in Dermatology. Every afternoon. Pathology course arranged.—THE NATIONAL HOSPITAL, Queen-square, W.C. Course in Neurology. Every afternoon. Demonstrations. Lectures at certain times.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, Feb. 13th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On MONDAY, Feb. 13th, and WEDNESDAY, Feb. 15th, at 2 P.M., there will also be demonstrations of gynæcological cases and eye cases by Mr. Aubrey Goodwin and Mr. N. B. B. Fleming respectively.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, W.

MONDAY, Feb. 13th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Dr. Trevor Davies: Gynæcological Department. 4.30 P.M., Dr. Snowden: The Anxiety Neurosis (lecture).

TUESDAY.—2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose and Ear Department.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. MacDonald: Genito-urinary Department. 2 P.M., Mr. Bishop Harman: Eye Department.

FRIDAY.—10 A.M., Dr. Pritchard: Special Medical Treatment Clinic. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department. 2 P.M., Dr. Shaw: Medical Out-patients. 4.30 P.M., Mr. Simmonds: Surgical Emergencies (lecture).

SATURDAY.—10 A.M., Dr. Burnford: Bacterial Therap
10 A.M., Dr. Owen: Medical Diseases of Children.
Medical and Surgical Out-patients, Operations, Speci
Departments, daily, 10 A.M. to 5 P.M., Saturday
10 A.M. to 1 P.M.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATIO
St. James's Hospital, Ouseley-road, Balham, S.W.

WEDNESDAY, Feb. 15th.—4 P.M., Dr. Stanley Wyar
Blood Transfusion.

NATIONAL HOSPITAL, Queen-square, Bloomsbury.

MONDAY, Feb. 13th.—2 P.M., Dr. Hinds Howell: Ou
patient Clinic. 3.30 P.M., Dr. Risien Russell: Crani
Nerve Palsies (1).

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clini
3.30 P.M., Mr. Armour: Cranio-cerebral Topography.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patie
Clinic. 3.30 P.M., Dr. Risien Russell: Cranial Ner
Palsies (2).

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M
Dr. Martin: Muscular Atrophies.

HOSPITAL FOR SICK CHILDREN, Great Ormond-stree
W.C.

THURSDAY, Feb. 16th.—4 P.M., Dr. Nabarro: Mode
Methods of Controlling Certain Infectious Diseases.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, Feb. 14th.—3.15 P.M. (at the Royal Che
Hospital), Dr. F. E. S. Willis: Early Diagnosis
Pulmonary Tuberculosis.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospit
49, Leicester-square, W.C.

TUESDAY, Feb. 14th.—5 P.M., Dr. G. B. Dowling: Staphy
coccal Infections.

THURSDAY.—5 P.M., Pathology Demonstration.

Births, Marriages, and Deaths.

BIRTHS.

BANNERMAN.—On Feb. 2nd, at Highclere, Alton, Hants, the wife of R. G. Bannerman, M.D., of a son.

BRADSHAW.—On Feb. 3rd, at Crouched Friars, Colchester, the wife of Dr. R. D. Bradshaw, of a daughter.

THOMAS.—On Jan. 31st, at Harley-street, the wife of C. Hamblen Thomas, F.R.C.S., of a son.

WIRGMAN.—On Jan. 30th, at Victoria-grove, W., the wife of C. Wynn Wirgman, M.D., F.R.C.S., of a son.

DEATHS.

MARSHALL.—On Jan. 31st, at a nursing home, Glasgow, George Balfour Marshall, M.D., F.R.F.P.S.G., Sandyford-place, Glasgow.

N.B.—*A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

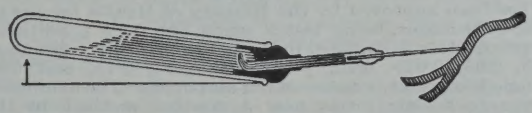
BLOOD CULTURE MADE EASY.

SINCE the days when the laboratory examination of blood first became of importance in clinical medicine pathologists have felt the need of some simple and safe method for the transmission of bacteriologically clean specimens of blood from the patient to the laboratory. Divers expedients varying according to the practice of individual laboratories have been evolved from time to time, but none has gained universal acceptance for the reason that none has been really satisfactory. The Behring Institute, of Marburg, Germany, have lately placed upon the market a device which would appear to offer the solution of the problem and which is as nearly foolproof as possible. The device consists of an evacuated glass test-tube, closed by means of

FIG. 1.

a stout hollow rubber cork with a short stiff nozzle; into the nozzle is let a glass tube, the end of which inside the hollow of the rubber stopper is bent at right angles in such a way that in the position of rest the outlet presses against the rubber and is thereby sealed; to the end of the tube outside the cork is sealed a stout hollow venipuncture needle, this in its turn being contained in a sealed glass tube. The whole apparatus (Fig. 1) is sterile when sent out. For use the sealed tube containing the needle is scratched with

FIG. 2.



a file and broken off, the needle thus being exposed; this is plunged into a vein in the usual way; as soon as blood enters the connecting glass tube the nozzle of the rubber cork is bent in such a way as to break the contact between the end of the tubing inside the test-tube and the rubber wall of the hollow stopper. Immediately this is done the negative pressure existing within the test-tube comes into play and sucks blood from the vein into the tube (Fig. 2); the rate of flow can be varied as desired by manipulation of the rubber nozzle. Though difficult to explain, the mechanism is simplicity itself and except in the most inexpert hands cannot fail but work. The whole apparatus is sold under the name of a "Venule," and these venules can be obtained either empty or filled with various solutions for the dilution of blood. Of particular interest to pathologists will be the venules containing nutrient media for the examination of blood by culture. Up to the present the impossibility of obtaining satisfactory samples of blood for this purpose has been one of the outstanding difficulties of clinical bacteriology. This difficulty would now appear to have been satisfactorily solved. The English agent for the "Venule" is Mr. W. Bredt, 41, Great Tower-street, London, E.C. 3.

A USEFUL PHOTOGRAPHIC COMPANION.

WE have received the "British Journal Photographic Almanac" for 1928. The annual is now in its sixty-third year and is a very helpful handbook for photographers, its 788 pages of letterpress and advertisements containing information of practical value. This includes illustrated articles on the service of photography in commerce, manufactures and in scientific investigation, from the aeroplane, and in big-game hunting; the use of the hand camera in recording objects of interest, especially during holiday periods, and amateur cinematography. In the Epitome of Progress practical hints are given and new methods of procedure described, while space is devoted to new cameras, lenses, and apparatus, and there is a full list of photographic societies and allied bodies in the British Isles. There are also useful formulæ and tables of exposure. The book is embellished with 64 gravure reproductions of camera pictures by noted exhibitors, and a full index makes reference easy. The annual is published by Messrs. Henry Greenwood and Co., Ltd., 24, Wellington-street, Strand, London, W.C., at 2s.

THE CHILD GUIDANCE COUNCIL.

A LECTURE will be delivered under the auspices of the Child Study Society by Sir Humphry Rolleston, President of the Child Guidance Council, on Feb. 16th, at 6 P.M. The subject will be Child Guidance and the lecture will take place at the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W. 1.

The establishment of child guidance clinics in America was one of the activities of the Commonwealth Fund.[1] That fund is now financing a "Child Guidance Council" in England and is considering the creation of a clinic where social workers could be trained and maladjusted children treated before they become neurotics or delinquents. This clinic is to be attached to a university and will, it is hoped, demonstrate to the public the need, value, and practicability of work on these lines. The Council, which consists of medical men, magistrates, educationists, social workers, and members of various associations and authorities, believes that clinics of this sort are essential if children are to be saved from lives of unhappiness and crime. It is hoped that the clinics, once started, will be carried on by local effort. The Commonwealth Fund has generously undertaken to train five social workers for one year in America, to meet the expenses of well-known persons, including the psychiatrist and psychologist appointed to the clinic sent to investigate American work, and to support two social workers in the British clinic for one year. No one who is acquainted with the problems of child life can question the need for an intelligent and wise handling of the situation, and if the Child Guidance Council can avoid the pitfalls of institutionalism it will do a work of immense national importance. The Secretary is Mrs. Beach, 24, Buckingham Palace-road.

NEW PREPARATIONS.

Sulphostab.—The word is a trade mark for dioxydiamino-arsenobenzol-sodium formaldehyde-bisulphite, and is manufactured by Boots Pure Drug Company, Nottingham. It is manufactured under the Therapeutic Substances Act, 1925, and has been approved by the Ministry of Health for use in public institutions, being tested under approved conditions. The preparation is supplied in the following doses: grammes 0·025, 0·05, 0·075, 0·10, 0·15, 0·20, 0·30, 0·45, and 0·60 in single boxes and in boxes of ten ampoules. The exhibition of organic arsenic forms now a routine method in the treatment of syphilis, and this preparation has been designed for hypodermic use in view of the known drawbacks that may be present either in the intravenous or the intramuscular technique. The yellow powder is packed in ampoules ready for dissolving in sterile water, no local reaction occurs at the site of injection, and the administration itself is painless. If treatment is commenced with a minimal dose, increased gradually, infants and small children can be treated with safety. The powder should be dissolved in distilled water immediately before use—1 c.cm. of water for each 0·05 g. up to a maximum of 3 c.cm. Whenever possible the solution should be made in the ampoule by first drawing the required amount of the distilled water into the syringe and then injecting the water into the ampoule. In the treatment of children for congenital syphilis and in cases of syphilis where intravenous injection is contra-indicated sulphostab has its obvious advantages, and good results are claimed for it in disseminated sclerosis and chronic skin lesions.

Emulsion B. Acidophilus.—This preparation, which is made by Messrs. E. H. Spicer and Co., Ltd., Watford, Herts, has in the commercial list the mark "MorBacT" to indicate that it was introduced (under the name of "Bactol") by Morgenstern, and has been renamed on the suggestion of the Council of Pharmacy of the American Medical Association. It is an emulsion of the *Bacillus acidophilus* which, like *B. bulgaricus*, will establish itself in the bowel, the claim being that it does so the more easily and effectively, as being a normal inhabitant of the intestinal tract. The emulsion, in the medium of liquid paraffin and agar, has found considerable employment in intestinal troubles and especially as a remedy for constipation. The good results obtained are substantiated by many medical contributions to the *Journal of the A.M.A.*, in all of which its value in intestinal toxæmia is brought out.

New-Promonta is an organic food preparation containing the lipoids of the central nervous system combined with the carriers of the known vitamins, lime, iron, hæmoglobin, highly concentrated albumins, and carbohydrates. The significance of lipoid substances in relation to cell economy has been noted by many bacteriologists, so that it was natural that experiments with the new food should be freely conducted. As a result the literature on the subject is considerable, one of the most detailed contributions appearing in the *Münchener Medizinische Wochenschrift* from Prof. E. Friedberger and his assistants. Their experiments have been made at the Research Institute of Hygiene and Immunity at Berlin-Daheim, and were made to ascertain the effect on rats of various kinds of bread exclusively after the ingestion of New-Promonta. The work was done at the instance of, and supported by, grants from the Academy for Women's Social and Pedagogis Work, the Imperial Ministry of Food and Agriculture, and the Prussian Ministry of Agriculture. It may be summarised by saying that the results of mixing New-Promonta with bread pointed clearly in some cases to a rise in nutrition. The preparation (which is obtainable from the Promonta Company, Ltd., 127–131 Regent-street, London, W. 1), it would appear from evidence received in this office, may be applied beneficially in various neurotic conditions, owing to its nutritive qualities.

From the British Organotherapy Company, Ltd., we have received a list of *Pluriglandular compounds* containing some new preparations which, it is claimed, have proved of considerable value in the conditions indicated. The compounds are presented in capsule form, in which form the activity of the glandular substances is best preserved. They include "Opocaps" Obesity Co. (male and female). "Opocaps" Pit-Mammary Co., indicated in menorrhagia, metrorrhagia, &c.; "Opocaps" Pit-Ovarian Co., indicated in amenorrhœa, dysmenorrhœa, &c.; "Opocaps" Pluri gland (male and female), indicated in asthenia, hypotension &c.; and several others. All the dosages in the compounds are stated to be adequate and in accordance with prove practice.

Messrs. Roberts and Co., of 76, New Bond-street, London W., inform us that *Elixir Sedoval*, a bromide salt of strontium combined with an extract of valerian, upon which we commented in these pages recently (Jan. 14th, p. 114), will to avoid a certain confusion that has occurred, be known as *Roboval*. A tablespoonful of *Roboval* contains grs. 6 of strontium bromide and 12 minims of extract of valerian and such a dose may be taken two or three times a day varied in accordance with the directions of the physician.

THE CARBON ARC IN THERAPEUTICS.

A BOOKLET with this title from the Amalgamated Photographic Manufacturers, Ltd. (3, Soho-square, London W.1), opens with a brief historical survey of light treatment and goes on to enumerate the conditions likely to be benefited by the use of artificial light. Emphasis is laid upon the reports of two workers (references given) that the carbon arc is better than the mercury vapour or tungsten for tuberculous adenitis or arthritis and for hyperpiesia. The spectra of different U.V. generators are compared and the claim is made that the carbon arc is the only therapeutic source directly comparable to the sun's radiation. The low U.V. region—i.e., 3000 to 2000 A.U.—is designated as noxious to the human organism, the erythema and pigmentation it produces being a protection against this harmful part of the radiation. Some improvements in open carbon arcs are described, including the multiple arc and the magnetic blower for lengthening the arc without necessitating an increase in the separation of the electrodes. The older arcs used very large currents, but the lamps described get a similar output by utilising impregnated carbons. Spectrographs of the metals in common use are shown; they extend well down into the low U.V. region and show the characteristic line spectra. The carbons advocated for use with the Marion lamp are the "Natural Sunlight," an impregnated type, but no spectograph is given showing the distribution of their output. The last section of the pamphlet deals with the Marion improved therapeutic multiple carbon-arc lamp. Several floor types are described and an overhead hanging model in which a silica tray catches any particles falling from the burning carbons. All the lamps are suitable for AC or DC and have four pairs of carbons in series (presumably for use on voltages above 200 —i.e., 50 volts per arc). Hand or automatic starting is available and a clever hand-operated rheostat coupled with the striking gear is available, the object of this device being to prevent the usual high current which flows when striking an open arc with a low value of resistance in circuit. All the lamps on the list are protected under Boardman patents and are obtainable by medical men through the usual agents.

FRANKLIN'S SUPER SURGEONS' GLOVES.

BY a new process Messrs. J. G. Franklin and Son, Ltd., 15, Colvestone-crescent, London, E. 8, are manufacturing surgeons' rubber gloves which do not easily tear or perish and which withstand repeated sterilising. It is claimed that the gloves do not harden in cold weather, and that they may be kept an indefinite period in any climate without fear of cracking, provided they are put in boxes or containers. The gloves are made with a smooth or roughened finish and their resistance of temperature indicates that they might be useful to surgeons accompanying expeditions.

Hunterian Oration

ON THE

PROGRESS OF SURGERY FROM HUNTER'S DAY TO OURS.

Delivered before the Royal College of Surgeons of England on Feb. 14th, 1928,

BY SIR HOLBURT WARING, M.S. LOND., F.R.C.S. ENG.

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, ETC.

TO-DAY, Mr. President and Gentlemen, we celebrate the two-hundredth anniversary of the birth of John Hunter, the founder of modern scientific surgery, the creator of our Museum, and the patron saint of our College. Since 1814 an oration—the Hunterian Oration—has been given, at first annually and then, after 1856, biennially, in this College in his memory. A large proportion of these orations have dealt with one or more of the numerous branches of Hunter's activities; in fact, it has always seemed to me that there is scarcely any part of the work of Hunter which has not been commemorated in one way or another in one of these orations.

On examining the conditions as given in the trust deed which created this oration it is stated that—

"The Oration is to be delivered in the theatre of this College on the 14th February and such Oration is to be impressive of the merits in Comparative Anatomy, Physiology and Surgery not only of John Hunter but also of such persons who have become deceased, whose labours have contributed to the improvement and extension of surgical knowledge."

The provisions of the trust creating this oration being so wide, I have thought it advisable on this occasion—the bicentenary of the birth of John Hunter—to devote the time allotted to me for the purpose and give a short review of the progress of surgery since Hunter's day to ours, in the course of which I propose to make reference to a few of the most distinguished scientific investigators, the results of whose work have proved to be of the greatest value to the science and practice of surgery.

Hunter has been regarded quite rightly, both in this country and to a lesser extent in foreign countries, as the practical founder of modern scientific surgery. After his earliest surgical days (1760–70) he formulated the idea that it was absolutely essential for a practising surgeon—who wished to practise his art with the greatest prospect of success and benefit to his patients—to have a very close and detailed knowledge of the structure and functions of man in health; that he should also be familiar with, again in every detail, the changes which take place in man during the onset, course, and development of any disease, which he is called upon to treat; and furthermore, that he should also have a comprehensive and detailed knowledge of the vital processes which take place in the tissues of the patient during the period of recovery from disease and after the performance of a surgical operation.

From these facts it will be seen Hunter fully realised that a minute and thoroughly comprehensive knowledge of the pathological processes occurring in inflammation and growth is the real basis of a considerable amount of practical surgery. This holds to the present day.

The method of investigation which Hunter appears to have carried out when examining any subject was the following. He first made himself master of the details and minute structures of an organ or tissue and then investigated its functions. In making these investigations he did not hesitate to compare the structures and functions of animals with those of man. After having made this extended structural and functional examination he reflected upon and reviewed the whole and then came to conclusions. After he had done this he then in a similar way investigated the structure and functions of organs and parts of living bodies in connexion with the onset, course, and result of disease. This consideration of structure and function in normal conditions, followed by a consideration of the structure and function in similar diseased conditions, is really the basis upon which Hunter commenced to make surgery a real science. He for one thoroughly understood that in order to fully comprehend the nature of a disease of an organ it is absolutely essential to be familiar with the structure and functions of such an organ under healthy conditions.

PHYSIOLOGY.

In connexion with the ideas which were formulated by Hunter concerning the practice of surgery, it is very interesting to read his physiological works and his speculations on the "basis of life." The condition of physiology in Hunter's student days was very little advanced. Hunter himself appears to have derived a considerable portion of his knowledge of physiological processes occurring in man from his direct observation of similar processes occurring in animals and even in plants, in addition to the modifications which he observed in man during the treatment of his patients.

The Vital Principle.—Concerning Hunter's speculations on the "basis of life"—he calls it the "vital principle." Hunter, like every true physiologist, instead of trying to theorise as to what was the exact chemical or physical basis of life, investigated all the signs and conditions under which life shows itself, and also dissected where possible, or examined in minute detail, all structures which showed signs of life. By these means he was able to formulate within his own mind what he himself understood by life or the "vital principle," or whatever the condition may be called.

Hunter believed that "life existed in every part of the animal body" and this life, or "vital principle," made every part of the animal body susceptible to the impressions which excite action. Animal matter he considered as a special or peculiar combination of other matter, and this animal matter, when endowed with life, had something added to it which he called "an arrangement of the most minute particles" or the "principles of life." His own crystallised conclusion as regards life may be expressed thus: "Life is a power superadded to matter, and is a property we do not understand; we can only see the necessary steps to it."

Since Hunter's day every advance in our knowledge of chemistry and physics has been used in attempting to explain the onset and course of disease, and the actual biochemical and biophysical processes which occur in living matter or matter endowed with the characteristics of life. So far, however, these researches have given us more enlightened ideas of the chemical and physical conditions under which "life" may exist and may be destroyed, but no ultimate chemical or physical explanation has been discovered of the true or real chemical or physical basis of life.

The first subject which I wish to discuss as being of supreme importance in the progress of surgery is what is now called

IMMUNITY AND PREVENTION OF DISEASE.

During the period of Hunter's life (1728–93) little or nothing was suspected or known of what we now describe as immunity. Jenner (1749–1823), an intimate friend and pupil of Hunter, was the first medical practitioner in this country to appreciate the great value of inoculation against disease. He noticed in his practice that milkmaids who had contracted cow-pox from the udders of cattle when milking did not take small-pox. According to Baron,[1] in his "Life of Dr. Jenner," the first inoculation was performed by Jenner upon a country boy aged 8½ years (named James Phipps), in May, 1796. He inoculated the boy with the matter obtained from vesicles upon the skin of a milkmaid suffering from cow-pox. Almost two years later in a similar manner he inoculated his own son along with several other children. As a result of these investigations inocula-

[1] Baron, J.: Life of Dr. Jenner, 1838, ii., 44.

tion of children with the exudation from the vesicles of persons suffering from cow-pox was used as a protection against the possible subsequent development of small-pox.

As we all now know, laity and otherwise, the ravages of small-pox have practically been set aside in this country by the systematic practice of vaccination. It is a very rare occasion nowadays in England to meet with anyone who has features disfigured with pits, the result of previous small-pox.

Biochemistry.

The discoveries in biochemistry, such as those of v. Behring (1854–1917), Koch (1843–1910), Ehrlich (1854–1915), and Wassermann (1866–1925), have given us very valuable means both of diagnosis and treatment.

Diphtheria Antitoxin.—v. Behring, in 1890, discovered the antitoxin of diphtheria and found that by injecting this antitoxin into patients affected with the disease diphtheria could be controlled and rendered practically innocuous. Up to that time a considerable proportion of patients suffering from diphtheria died from one condition or another, a large number of them having to be submitted to tracheotomy on account of laryngeal obstruction due to diphtheritic membrane. In England, at the present day, owing to the general use of v. Behring's diphtheria antitoxin, it is extremely rare to see a patient suffering from diphtheria in whom tracheotomy is necessary. At St. Bartholomew's Hospital, in my student days, tracheotomy for tracheal obstruction due to diphtheria was a very common operation. Nowadays it is practically never seen. In 1890 the number of patients treated in this way was 47 and in 1927 there were none.

Antitetanic serum, which was discovered by v. Behring and Kitasato in 1892, was used extensively in the prevention and treatment of tetanus during the Great War. The soil of the low-lying lands of Flanders is said to be almost always infected with the bacillus of tetanus (discovered by Nicolaier in 1884); hence gun-shot wounds sustained by soldiers in this area were prone to become infected with the organism which caused an attack of tetanus. It has been stated that the death-rate among inoculated soldiers suffering from tetanus during the Great War was 23 per cent., as compared with 53·5 per cent. in those who had not received preventive treatment. Other diseases which have been treated successfully either by prevention or cure in a similar biochemical manner are hydrophobia, typhoid, and anthrax.

Many attempts have been made to render patients immune from streptococcus infection by the injection of vaccines. At the present time, however, it does not appear that any certain remedial measure, biochemical or otherwise, apart from surgical asepsis, has been found which can be relied upon for absolutely preventing the occasional occurrence of a streptococcal or staphylococcal infection after an operation. Some success has been claimed to have been obtained with antistreptococcal serum in connexion with possible infection, but the exact value of this is not clear at present. Certainly, in my experience, there is no streptococcal antitoxin or serum which can be injected into a patient and be relied upon to absolutely prevent or cure infection with virulent pathogenic streptococci in all cases.

Insulin.—The biochemical researches of Banting and Best, of Toronto, in 1921 and subsequently, led to their discovery in, and isolation from, the pancreas of a substance which was named "insulin." The administration of this substance so improved the metabolism of carbohydrate material by diabetic patients that in many cases operations which previously had been thought inadvisable and dangerous have been rendered possible, and the lives of a large number of patients very considerably prolonged. Best has recently stated that in his opinion the lives of about 200,000 diabetic patients have been temporarily saved by the use of insulin.

Anæsthesia.—Another most important epoch in the progress of surgery was the discovery of general and local anæsthesia. Although a certain amount of anæsthesia, usually induced by inhalation or taking internally of narcotic substances, such as mandragora, hyoscyamus, certain types of hemp, and opium, had been practised during surgical operations in early days; in Hunter's time this method of alleviation or diminution of pain seems to have been practically entirely forgotten and to have gone out of use.

As I have already said, every discovery of importance in chemistry and physics which has been made since Hunter's day can truthfully be said to have been utilised sooner or later by application to surgical diagnosis and treatment. Thus the discovery of hydrogen in 1766 by Cavendish, nitrogen in 1772 by Rutherford, and oxygen and nitrous oxide gas in 1774 by Priestley, were the real beginnings of the application of chemical substances for the production of anæsthesia in surgical operations. Nitrous oxide gas appears to have been made use of first as an anæsthetic for the diminution of pain in the extraction of teeth. It is stated that Humphry Davy, about 1800, had used this gas for the alleviation of pain due to a diseased tooth. He afterwards stated as a result of this experience that "nitrous oxide seems capable of destroying pain. It may be used in surgical operations where there is no great effusion of blood." Unfortunately, this suggestion of Davy's was not made use of by surgeons, and it was almost 50 years later that the value and use of nitrous oxide gas for the induction of anæsthesia was appreciated and understood. Faraday, another chemist, seems to have been one of the first to recognise the anæsthetic properties of ether. In 1818 he pointed out that "when the vapour of ether is mixed with common air and inhaled the effects are similar to those caused by the inhalation of nitrous oxide."

From this period onwards a number of observers made use of the inhalation of gases to diminish pain during surgical procedures. Henry Hill Hickman—a young man—who became a Member of this College in 1820 and practised in Ludlow, Shropshire, from 1820–28, made experiments, in the autumn of 1823, on the possible anæsthetisation of animals, at first with carbonic acid and then with nitrous oxide. His proposals concerning the use of nitrous oxide gas for the production of anæsthesia and its utilisation in connexion with surgery were received very sceptically and generally condemned by the surgical profession of this country. So much so that he communicated with the King of France asking that an inquiry be made by the physicians and surgeons of that country as regards the value and correctness of his experiments. The communication was sent to the Académie Royale de Médecine de Paris, which body appointed a committee to investigate the matter. Nothing, however, came of this, although Hickman requested that he might be allowed to demonstrate the result of his experiments to the Paris Academy. Unfortunately, this young and enterprising surgeon died from tuberculosis the following year at the age of 29.

Inhalation of ether and also of chloroform seems to have been practised as a means of intoxication by young men in the fourth decade of the nineteenth century. At first the drug was only inhaled to produce intoxicating results, but by an accident its anæsthetic properties were discovered. In 1839 a negro boy, who appeared at a festivity in Athens, Ga., while ether was being inhaled by the participants, refused to take part. Some of the youths forcibly placed a handkerchief soaked with ether over his mouth and nose. After a struggle the young negro became quiet and his tormentors desisted. Instead of getting up he remained asleep and did not wake up until one hour afterwards. This seems to be the first instance of prolonged anæsthesia by the inhalation of ether.

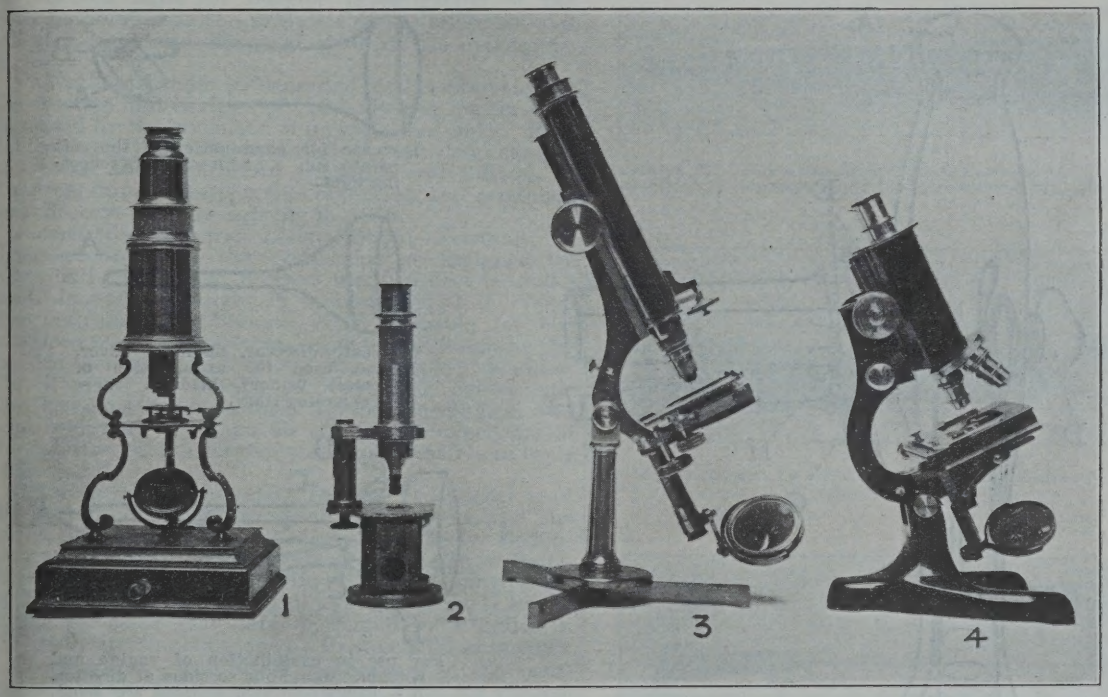
Crawford Long, a medical practitioner in Georgia, appears to have been the first American surgeon to make use of ether in the production of anæsthesia during the performance of a surgical operation. On March 30th, 1842, he gave ether to a patient for the removal of a tumour from the neck. This case being so successful Long continued to make use of ether

gical operations, and performed eight such operations between 1842–45. Long, although he made no secret of his discovery, did not publish the fact to the world, and it was not until others had made a similar discovery that his experience became generally known. Two years later, in 1844, Wells, a dentist in Hartford, Conn., made use of anæsthesia by nitrous oxide for the extraction of teeth. Although Wells had attempted to produce anæsthesia with ether, he had not been able to continue to do so owing to the difficulties and choking sensations which were produced. Morton, however, who had been a pupil of Wells, was familiar with the properties of ether and independently discovered its anæsthetic qualities four years after Recently a most important combination which has been made use of is that of nitrous oxide, oxygen, and a small amount of ether or chloroform. This combination is especially useful and safe when administered by the intratracheal method.

Local Anæsthesia.

Cocaine.—I now come to "local anæsthesia." Cocaine as an alkaloid was first isolated apparently by Godeke about 1855 and some points as regards its power of producing local anæsthesia were noticed. No definite advances were made, however, until 1874, when Bennett showed that cocaine, applied to living tissues, had the power of causing local anæsthesia.

Fig. 1.



Illustrates examples of microscopes used from Hunter's day to ours, including those used by Pasteur and Lister. 1 = Microscope of 1760. 2 = Microscope used by Pasteur. 3 = Microscope used by Lister in his work on the circulation in the frog. 4 = Microscope as used to-day.

[*Copyright: Wellcome Historical Medical Museum*

discovery by Long. Apparently the first public exhibition of surgery without pain was given in Massachusetts General Hospital in October, 1846, when a patient was operated upon by Warren for removal of a vascular tumour of the neck after being anæsthetised with sulphuric ether.

Ether was first used in England for the induction of general anæsthesia during the performance of an operation (removal of a tooth) in December, 1846, and two days later ether was administered to patients at University College Hospital by Squire for Liston, who amputated the lower extremity through the thigh in one patient, and also in another removed an ingrowing toe-nail. During the following year (1847) Simpson, of Edinburgh, used ether in obstetric practice and found the pains of labour could be abolished thereby, whilst the uterine contractions were not interfered with. The next year (1848) Simpson, who was somewhat dissatisfied with the use of ether on account of the irritation which it produced in the lungs and bronchial passages, first made use of chloroform. This substance was first discovered at about the same time by Soubeiran (in 1831) and Liebig (in 1832), and its composition was first accurately described by Dumas in 1835. Since this period (1847–48) ether, chloroform, nitrous oxide, in many and various combinations, and other substances, have been used for the induction of surgical anæsthesia. V. Anrep, however, in 1878 appears to have been the first to completely investigate the anæsthetic properties of cocaine by injecting a dilute solution (0·003–0·5 per cent.) underneath the skin, and in connexion with this made the suggestion of its possible value for producing anæsthesia for surgical operations.

In the following year (1879) its powers of producing local anæsthesia were demonstrated in connexion with the eye. This use of cocaine was worked out in complete detail by Karl Koller, who showed that complete anæsthesia of the eye could be produced by the use of a 2 per cent. solution. The results of Koller's experiments were first published and discussed at an ophthalmological congress in Heidelberg in 1884. Since then this drug has been used increasingly for the production of anæsthesia in all kinds of surgical operations. In the early stages of its use some difficulties were met with in connexion with poisoning by absorption, but these were soon overcome.

Novocaine.—Considerable progress in the method of induction of local anæsthesia has been made since that date by the discovery of novocaine, a synthetic product derived from coal-tar (para-amido-benzoyl-diethyl-amino-ethenol hydro-chloride), by Alfred Einhorn in 1905. So much so that at the present time a considerable number of major surgical operations, such as removal of tumours of the thyroid, gastrostomy, radical operation for hernia, and

even almost any major and minor operations, can be done painlessly and in certain cases with greater safety to the patient, by the use of a dilute solution of novocaine, administered by the infiltration method.

Stovaine.—Another variety of anæsthesia, or analgesia—spinal—can be induced by the injection of a solution of stovaine into the lower portion of the spinal theca. This form of anæsthesia is especially used in operations on the portion of the body below the diaphragm, such as prostatectomy or hysterectomy, when there are contra-indications, such as affections of the lungs, to the administration of a general anæsthetic.

The net result of all these discoveries and improvements in connexion with surgical anæsthesia—general and local—is such that almost any desirable and justifiable operation can now be performed by the dexterous surgeon well trained in anatomy and technique, painlessly and with very slight anæsthetic risk to the patient, when the administration of the anæsthetic is carried out by a well-trained anæsthetist.

PATHOLOGY AND MICROSCOPICAL DIAGNOSIS.

The publication of Virchow's (1821–1902) work on "Cellular Pathology" in 1858 was a great incentive to surgeons to study the histological basis of a considerable number of surgical diseases, especially all forms of new growth. From this period (1858) to the present time there has been a continuous advance in our knowledge of the pathology of surgical affections, one of the latest, perhaps, being the recognition of the different histological characteristics of malignant growths. This has enabled surgeons to be in a mu better position as regards giving a correct prognos after an operation for malignant disease. The advances have been made possible by the improve construction of the microscope and the knowledge the reactions of human and other tissues to differe varieties of dyes and stains. The improvements whi have been made in the microscope since Hunter's da have been very considerable. In Hunter's time th microscope was an instrument which was little mo than a simple magnifying lens.

Compound Microscope.—The principles of th compound microscope were discovered and develop by many physical observers, one of whom was Josep Jackson Lister, the father of Lord Lister, in 18

The discovery of the principle of the homogene immersion lens, followed by great improvem in the construction of lenses, which were ca apochromatic, have enabled a large number researches in histology and bacteriology to be possi Fig. 1 illustrates examples of the microscopes in se from Hunter's day to ours, including the microsco used by Pasteur and Lister. (Fig. 1.)

Use of Reflected Light.

The first surgeon to utilise reflected light in h investigation of deep spaces or cavities of the body a Bozzini,[2] of Frankfurt-am-Main, who invented in 1805, a form of urethroscope and also other form

[2] Bozzini, Dr.: Lichtleiter, eine Erfindung zur Anscha innerer Theile und Krankheiten, Neues Jour. d. p Heilkunde, 1806, xvii., 107.

"-scopes." Each consisted of a hollow tube along which light was reflected by a mirror. (Fig. 2.) No practical results, however, emanated from this discovery at the time, and its use remained quiescent apparently for a considerable period.

The next observer to make use of reflected light in the examination of patients was Helmholtz, who invented the ophthalmoscope in 1851. The original ophthalmoscope which he invented was, as regards its success in working, dependent upon the reflection and concentration of a source of light, usually a candle or a lamp. By its use ophthalmology became established on a scientific basis. Soon afterwards, in 1855, Manuel Garcia invented the laryngoscope, which was used by Toek, of Vienna; then followed the rhinoscope, discovered by Johann Czermak in 1859. Nitze and Leiter made the most rapid advances in the utilisation of reflected light for interior investigation of the body by combining the principle of the telescope and reflected light and the production of the cystoscope in 1877.

The value of these instruments for investigation of the recesses and cavities of the body was enormously increased by the invention of incandescent light. Paul Jablochkov, in 1876, invented the electric candle, and Swan and Stearne, of England, and Edison, of America, improved upon this invention and produced incandescent electric lighting in 1880.

Incandescent Electric Light.—David Newman, of Glasgow, improved the cystoscope as designed by Nitze and Leiter, and in 1883 was the first to make use of incandescent light in connexion with it. With this instrument it became easily possible for the practised manipulator to investigate and diagnose the various conditions affecting the urinary bladder. Fig. 3 gives the details of Newman's cystoscope. The laryngoscope was also further developed and improved, and the diagnosis of surgical affections of the interior of the larynx was made possible in their early stages.

Other forms of "-scopes" for the investigation of the interior of the body which rapidly followed the earlier discoveries were the sigmoidoscope by Bodenhamer in 1863, afterwards perfected by Kelly, of Baltimore, and Strauss, of Berlin; the œsophagoscope by Kussmaul in 1869, as well as the first gastroscope during the same year (later perfected by Mikulicz in 1881, and the bronchoscope by Gustav Killian in 1898.

Thoracoscope.—The latest application of the combination of the telescope and electric light for clinical and diagnostic purposes is the thoracoscope. This is in reality a slight modification of the straight cystoscope such as is used for the investigation of the urinary bladder in children. In using it a trocar and cannula are passed into the pleural cavity on the side which it is wished to investigate and an artificial pneumothorax is induced, and then the interior of the pleural cavity and anything projecting into it are visually investigated through the telescope of the instrument. A similar but much larger instrument is used for investigation of the interior of the stomach. In practiced hands the use of this instrument has given, in a limited number of cases, moderately good results, but in the diagnosis of doubtful cases the appearances seen through it cannot be looked upon as definitely pathognomonic. The practical value of the gastroscope, however, in diagnosis is problematical, owing to the difficulty of correctly interpreting the conditions seen through it, and the fact that it cannot be used easily when a patient has been anæsthetised.

Lithotrite.—One example of the application of improved mechanical methods to surgery was the invention of the lithotrite and vesical evacuator by Bigelow in 1878. With this instrument patients were successfully treated and cured of stone in the urinary bladder without any cutting operation. Since Bigelow's day the instrument has been considerably improved in detail, including the addition of a cystoscopic attachment, though the essentials are absolutely the same. Expert operators can obtain excellent results by this method. In hot and tropical countries such as Egypt and India, where stone is prevalent and the natives are not readily amenable to the discipline—aseptic and otherwise—necessary for a successful surgical operation, this method in the hands of the skilled operator has enormous advantages.

Bacteriology.

The next avenue of progress in surgery is that branch of biology and biochemistry which we call bacteriology. Hunter, of course, was ignorant of bacteriology, since bacteria had not been discovered in his day. It is of interest to note that in his surgical lectures, given in 1785, he states in connexion with fermentation: "Fermentation appears to be a process peculiar to dead vegetable or animal matter, and when

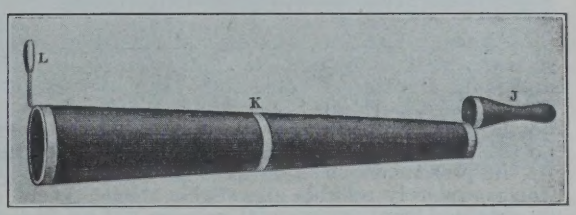
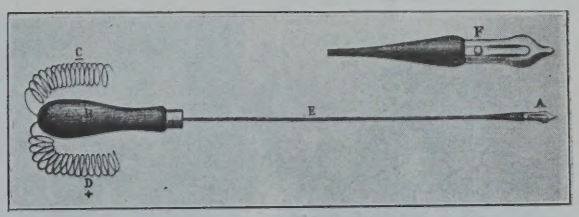
Speculum (G). Cover (to protect glass disc and facilitate introduction) in position, ready for introduction into bladder.



Cover (J) rotated by handle (L). In position after it has been introduced into bladder.



F = Electric lamp. A, B = Lamp and handle. Connected with the handle (B) by a thin rod (E), in which the wires from the battery run. The lamp, when connected with two Grove's cells, gives light equal to one candle.

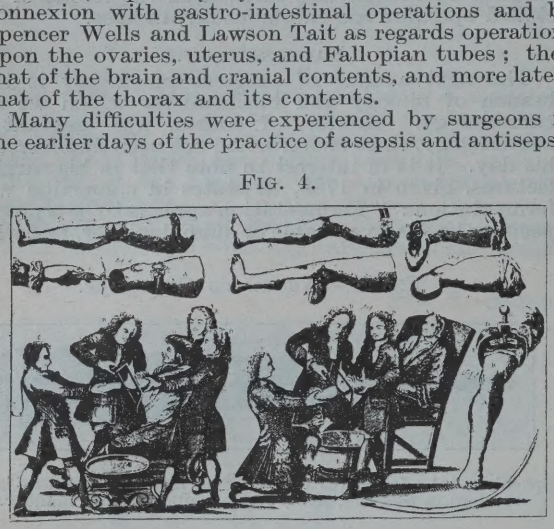
we find a tendency to fermentation we may conclude that there is a defect of the living principle." The modern science of bacteriology and its possible application to surgery really commenced in 1857, when Pasteur published his paper on Lactic Fermentation and subsequently his paper on the Influence of Oxygen on the Development of Yeast and on Alcoholic Fermentation in 1861.

Antisepsis and Asepsis.—The adoption by Lister of his antiseptic doctrine in connexion with surgery in 1867, which really followed the work of Pasteur, was the commencement of what may be known as advanced surgery on a scientific basis. The general acceptance of Lister's doctrine and its application to practical surgery was slow in this country. However, in the late 'eighties and early 'nineties its practice became general and was quickly followed by the aseptic doctrine. The practice of modern surgery is really based on a combination of antisepsis and asepsis, principally the latter. All the points, however, on the subject of Lister were discussed by you, Mr. President, on this day last year. It is sufficient for me to say that the practice of asepsis and antisepsis in surgical operations has enabled surgeons to submit to operation

with success every organ and almost every part of the human body. The surgery of the abdomen was first perfected, especially by von Billroth, of Vienna, in connexion with gastro-intestinal operations and by Spencer Wells and Lawson Tait as regards operations upon the ovaries, uterus, and Fallopian tubes; then that of the brain and cranial contents, and more lately that of the thorax and its contents.

Many difficulties were experienced by surgeons in the earlier days of the practice of asepsis and antisepsis

FIG. 4.



Amputation in Hunter's days.

in procuring entirely reliable "sterilised absorbable suture and ligature material." Lister attempted to make his "catgut" antiseptic by soaking it in carbolised oil. [Here Sir Holburt Waring showed a bottle illustrating the method used by Lister, the bottle being the one which was actually used by him.] At the present day by improved methods of preparation completely reliable absorbable sterile catgut can be obtained from commercial sources, put up in sealed glass tubes which can be boiled before use.

[The orator here illustrated the extent of the progress of modern operative surgery in one

FIG. 6.

aspect by a skiagram of a tumour of the chest in which the position, extent, and relations were shown. It was a representation of the chest being opened and a tumour removed, the patient having been anæsthetised and positive intratracheal pressure induced by the anæsthetist so as to enable the patient to breathe satisfactorily after the lung has collapsed.]

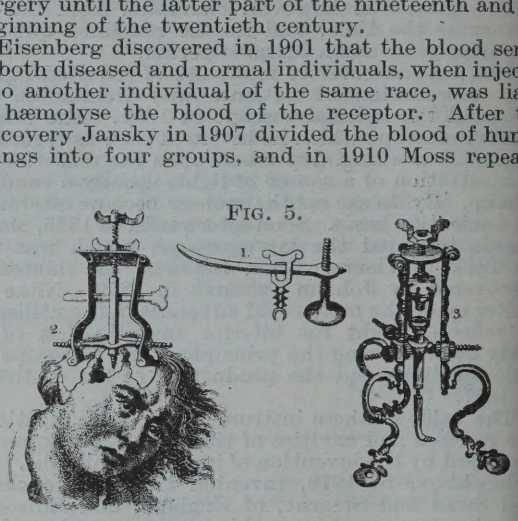
The net result of the practice of asepsis in operations is that infection of, and suppuration, in operation wounds is almost non-existent in most modern hospitals, and the mortality from surgical operation has been very greatly reduced.

TRANSFUSION OF BLOOD AND ITS APPLICATION TO SURGERY.

Transfusion of blood, either directly from one individual to another or indirectly, was first practised apparently on animals by Lower in 1665 and in man by Denys, of Paris, in 1667. No serious progress was made, however, in the application of this procedure to surgery until the latter part of the nineteenth and the beginning of the twentieth century.

Eisenberg discovered in 1901 that the blood serum of both diseased and normal individuals, when injected into another individual of the same race, was liable to hæmolyse the blood of the receptor. After this discovery Jansky in 1907 divided the blood of human beings into four groups, and in 1910 Moss repeated

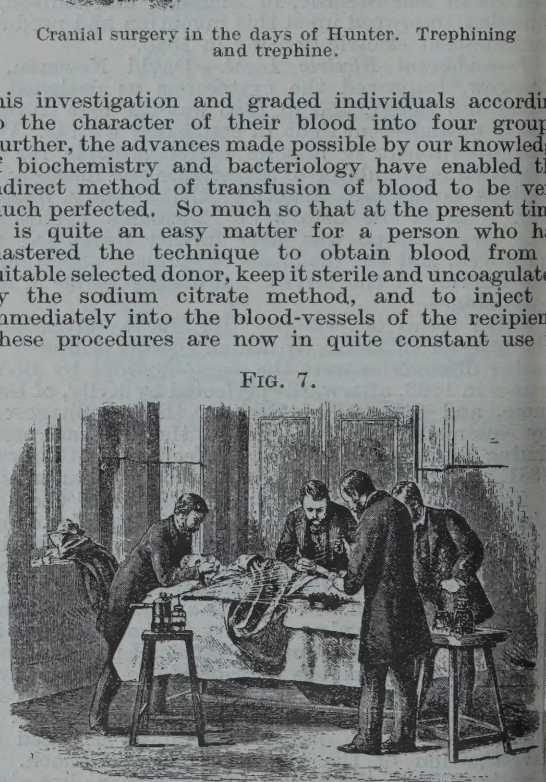
FIG. 5.



Cranial surgery in the days of Hunter. Trephining and trephine.

this investigation and graded individuals according to the character of their blood into four groups. Further, the advances made possible by our knowledge of biochemistry and bacteriology have enabled the indirect method of transfusion of blood to be very much perfected. So much so that at the present time it is quite an easy matter for a person who has mastered the technique to obtain blood from a suitable selected donor, keep it sterile and uncoagulated by the sodium citrate method, and to inject it immediately into the blood-vessels of the recipient. These procedures are now in quite constant use in

FIG. 7.



Operation being performed in early days of Listerian practice.

hospitals and surgical practice in certain types of serious injury or disease, especially when a large amount of blood has been lost by the patient, and have proved of great advantage in enabling operations to be done and the lives of patients saved thereby which otherwise would have been lost.

RADIOLOGY.

Another "milestone" in the progress of surgery between Hunter's day and ours is marked by the successive discoveries of X rays and radium.

The discovery of X rays by Wilhelm Roentgen (1845–1923), professor at Wurzburg, in 1895, was the commencement of a series of great advances in surgical diagnosis. At first the use of X rays in this direction was mainly confined to injuries to and diseases of the bones. When, however, the possibilities of this discovery were more appreciated and understood the

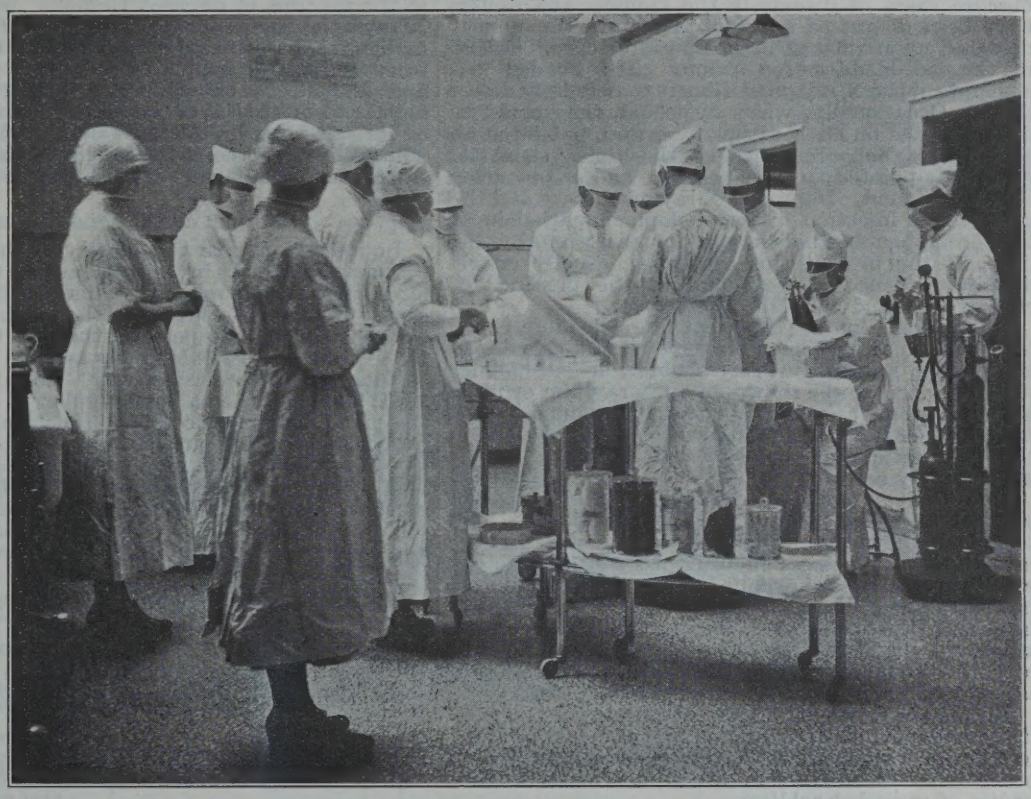
The determination of the position of deep-seated fistulous conditions between the viscera has also been made possible. As an example I saw demonstrated recently by this method a fistulous track between the surface of the body in the lower lumbar region and the lumen of the second portion of the duodenum.

FIG. 8.



A modern operation in course of performance: general arrangements.

FIG. 9.

An operation under modern aseptic methods: gastro-enterostomy.

The value of X rays in connexion with the diagnosis and treatment of disease has, in many cases and especially by the laity, been much exaggerated. To the practising clinician X rays, when intelligently and scientifically used, as we all know, can be of enormous advantage. They are of great value in the detection and localisation of different forms of calculi, especially those in the ureters and kidney. One of the later developments of the use of X rays in diagnosis is the investigation of the ureters and pelvis of the kidney by what is known as "ureterography" and "pyelo-

graphy." By these means of investigation many obscure cases of disease in the kidneys and ureters have been diagnosed satisfactorily and subsequently operated upon with great prospects of cure. Calculi in the gall-bladder for a long time evaded the attempts of the X ray practitioners to definitely detect them. Occasionally, when suspected, they could be demonstrated on an X ray plate or film, but often no evidence was apparent, although the clinical signs and symptoms pointed to their presence and at operation they were found. Improved X ray machinery and the intravenous injection of tetraiodophenolphthalein or tetrabromphenolphthalein and its excretion by the liver, at the present time, however, usually enable definite evidence to be found of the presence of cholecystitis and calculi in these cases.

As everyone knows, a patient is much more ready to submit to an operation for removal of a calculus in the ureters, kidneys, urinary bladder, or gall-bladder if its presence can be shown on an X ray film or plate than if it is only assumed. In a similar manner X rays have been of use in detecting the presence of stone in the pancreatic duct or deep-seated calculi in the submaxillary salivary gland.

One disadvantage of the use of X rays in diagnosis of surgical affections at the present time is the high technical knowledge which it is requisite for the investigator to possess in order to get satisfactory results in all classes of examination. X ray machinery, however, has been much improved and simplified of late and the principles of its use more understood, so that ordinary investigations can now be carried out more or less successfully by technical assistants.

During the Great War X ray diagnosis was increasingly made use of in the detection and localisation of injuries to bones and the presence of bullets and other metallic substances which had entered the bodies of wounded soldiers.

Following the discovery of X rays by Roentgen, Monsieur and Madame Curie in 1898 discovered radium in pitch-blend derived from mines in Joachimstal in Bohemia (now Czecho-Slovakia). The salts of this metal were found to possess very marked radio-active qualities and have been used, especially of recent years, in the treatment of various diseases and particularly in forms of new growth. There is no doubt that certain types of both sarcoma and carcinoma are very sensitive to the action of radium, and a number of patients have apparently been cured by the use of the salts of this metal. Radium has been applied in various ways, but in the treatment of disease the best results have been obtained either by the implantation of radium needles or radium seeds in the margins of diseased tissues. As in the case of X rays, the exact value of radium in the treatment of malignant disease cannot yet be determined. Unfortunately, a large supply of radium is very expensive and difficult to obtain. The indications, however, appear to be that if an increased quantity of radium or its salts can be obtained and made available for clinical use, then considerably improved results in the treatment of malignant disease may be made possible.

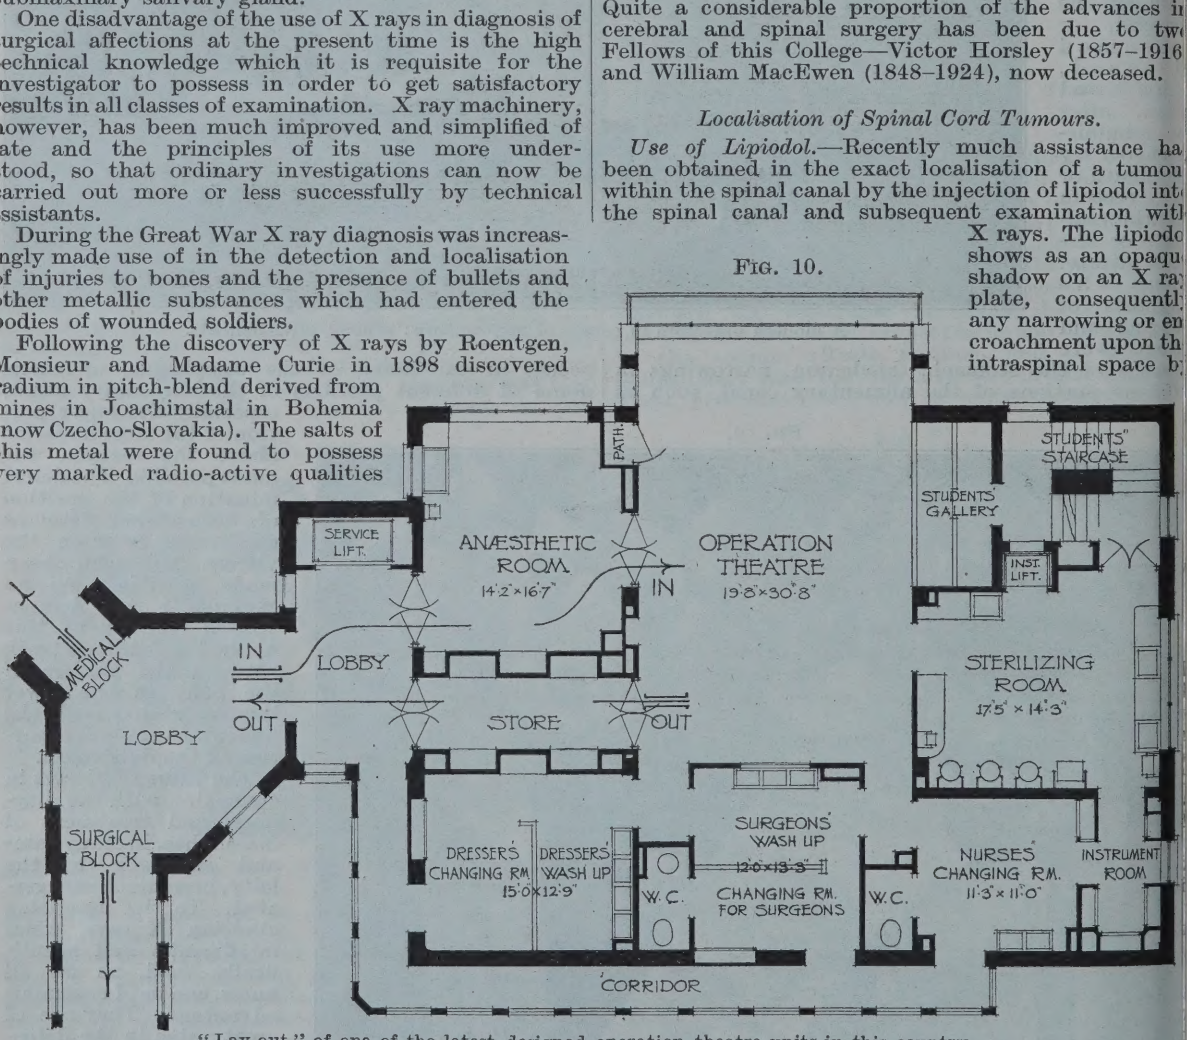
Cranium and Cranial Surgery.

In connexion with the surgery of the cranium and its contents Broca's investigations into the localisation of function and especially his localisation of the centre of articulate speech in the left frontal convolution enabled him to perform the first fixed operation for cerebral abscess, which was assisted by localisation of function in connexion with "motor aphasia," in 1861, and since then a large number of researches into the localisation of cerebral functions has enabled neurologists and neuropathologists to localise the site of a considerable number of intracranial growths. Quite a considerable proportion of the advances in cerebral and spinal surgery has been due to two Fellows of this College—Victor Horsley (1857–1916) and William MacEwen (1848–1924), now deceased.

Localisation of Spinal Cord Tumours.

Use of Lipiodol.—Recently much assistance has been obtained in the exact localisation of a tumour within the spinal canal by the injection of lipiodol into the spinal canal and subsequent examination with X rays. The lipiodol shows as an opaque shadow on an X ray plate, consequently any narrowing or encroachment upon the intraspinal space by

FIG. 10.



"Lay-out" of one of the latest designed operation theatre units in this country.

a tumour becomes evident. Similarly injection of lipiodol into the trachea, bronchi, and lungs, and subsequent examination by X rays has enabled the clinician to positively demonstrate on plate or film the extent and nature of abnormal intrathoracic conditions.

SPECIALISATION.

The numerous methods—chemical and physical—available to the clinician and the pathologist for the

vestigation of patients suffering from surgical fections are so varied that at the present time it is ot usually possible for one diagnostician to make all ie investigations which are necessary in the examina- on of an individual patient. Thus in the practice of irgery in the present day we have skilled specialists many branches, such as histology, biochemistry, rtology, bacteriology, and radiology, and further, in ie use of special instruments, such as the laryngo- ope, ophthalmoscope, cystoscope, sigmoidoscope, be treated in an institution built and equipped for the scientific investigation and treatment of disease.

Influence of Asepsis and Antisepsis on the Construction and Building of Surgical Hospitals and Operation Theatres.

The general adoption in surgical practice of the principles of asepsis and antisepsis was quickly followed by enormous improvements in the building and construction of surgical hospitals and operation

Fig. 11.

ows interesting examples of amputation knives from Hunter's day to ours. 1 and 2 = Curved amputation knives as used in Hunter's day. 3 and 4 = Amputation knives of period 1820. 5 and 6 = Amputation knives of present day.

[*Copyright: Wellcome Historical Medical Museum.*

id bronchoscope. This division of activities has led the establishment of specialist practitioners, many whom limit their activities, diagnostic and otherwise, one particular organ.

From the point of view of progress in surgery there no doubt that this specialisation, both in diagnosis id treatment, has been a very considerable advantage. his trend to specialisation in both diagnosis and eatment has become so marked that at the present me there is a tendency for specialist-practitioners to ork in teams, each one of a team taking specialised rtions of either investigation or treatment.

In practice this method of examination and treat- ent has been found especially feasible in connexion ith hospitals to which medical schools are attached. he formation of private clinics for the diagnosis and eatment on these lines for the non-charity patient is not been easy in this country. Many develop- ents, however, on these lines are now taking place hich will be of great advantage to the successful ractice of surgery in the future.

One great difficulty often arises in connexion with ie progress in surgery as regards its practical applica- on. This is the inborn desire of the Englishman to ave all forms of medical and surgical treatment rried out in his own house. Fortunately public inion is gradually being educated on this subject id there is an increasing tendency in educated embers of the community, of desiring, when ill, to theatres. In Hunter's day a small room, not specially built to fit it for the purpose, was generally made use of as an operation room. This practice of using any small and otherwise useless room for operations was continued until comparatively recently. In my own student days I well remember, in one of the large special hospitals in London, that the residents' sitting-room and dining-room were also used as the surgeon's operation and instrument rooms. The old method of erection of buildings was ill adapted for the practice of asepsis owing to the large number of angles, corners, crevices, wall and ceiling decorations, which formed collectors of dust, dirt, and associated micro-organisms.

Since the late eighties and early nineties enormous advances have been made in the construction of surgical wards and rooms used for surgical patients and also operation theatres. In the earlier days of the construction of the modern operation theatre considerable difficulty was experienced by architects and builders in providing absolutely smooth surfaces for floors, walls, and ceilings, which could be readily cleaned without being damaged or destroyed. At the present time the tendency in the construction of surgical operation theatres is to make them as simple as possible and to have all the sterilisation of equipment and instruments carried out by superheated steam or in some cases dry heat produced electrically in a room immediately adjoining the operation theatre.

In connexion with this subject the illustrations are of considerable interest, both as regards the operation room, operation table, and the equipment and personnel of the surgeon and his assistants. Figs. 4 and 5 illustrate operations being performed in the days of Hunter. Fig. 6 represents the arrangements for an operation in 1820. Fig. 7 represents an operation being performed in the early days of Listerian practice. In it can be seen the carbolic spray which was used for making the atmosphere in the region of the operation aseptic. Figs. 8 and 9 illustrate an operation being performed under modern aseptic methods.

As an illustration of the progress which has been made in ensuring surgical cleanliness and asepsis in an operation Fig. 10 gives the lay-out and design of one of the newest and most modern surgical operation theatre units in this country. The main point in connexion with this lay-out is the provision made for avoiding the entrance into the operation theatre of any individual or material which has not been rendered previously as aseptic as possible.

The progress of surgery, especially since the aseptic and antiseptic era, has been greatly assisted and rendered possible by improvements in the education and training of nurses. Without these improvements in the education and training of nurses it would be almost impossible to perform with success a large number of the major operations which are now regularly done in the practice of surgery.

Surgical Instruments.

Since Hunter's day there has been a gradual improvement in the size, shape, and finish of practically all surgical instruments. As illustrations of this, these are two instruments which I have taken from the case containing the Hunterian relics in our museum. The first one is a lithotomy knife used by Hunter. As you see it is a large unwieldy instrument of very coarse manufacture. This second one is a knife of a similar kind which may be used at the present time. The second is a flexible metallic catheter as invented and used by Hunter. Since that period the structure and manufacture of flexible catheters has been much improved, especially since the utilisation of rubber and its products.

Fig. 11 shows interesting examples of amputation knives from Hunter's day to ours. The specimen I show you was one in use in the days of Hunter. This form of knife continued to be used until the days of Anthony Carlisle, a former President of this College, who introduced the straight knife and discarded the curved and heavy form of knife. Since then the tendency has been for an amputation knife to become smaller and smaller until at the present day it is usual to use a short knife such as shown in the figure.

War Surgery.

The great progress in war surgery during the Great War was due to the utilisation, in all aspects, of previous discoveries in connexion with (*a*) immunity and prevention, (*b*) anæsthesia, (*c*) asepsis and antisepsis, and (*d*) X rays. The utilisation of these discoveries during the prolonged hostilities enabled operations of every magnitude to be carried out in advanced stations and hospitals within close distance of the firing-line. In addition the improvements in transport, motor and otherwise, contributed greatly to this progress.

Two points which I have already referred to in connexion with the progress of surgery had great bearing on the surgery of war. These were preventive typhoid inoculation and the use of antitetanic serum. Another important practice developed during the war in connexion with the treatment of recent contaminated wounds, the margins of which were lacerated or contused, was primary excision of all contaminated and contused tissues followed by immediate or delayed suture. By the practice of these methods and the advantages of improved transport, it was found possible during the war to treat patients at the general military hospitals in London within 24 hours after the wounds had been received. In a number of cases of wounds the margins of which had been excised, the cavity was packed with gauze soaked in flavine, or after amputation the stumps were treated in a similar way.

A further improvement in war surgery was the recognition of the fact that in many cases of suppurating wounds or badly lacerated limbs in which an amputation had to be performed, the wounds could be left open and treated by the Carrell-Dakin irrigation method. Free exudation and associated irrigation enabled the wounded surfaces to become clean and delayed suture of the wound could be carried out afterwards. As a result of the treatment of war wounds on improved biochemical and biophysical principles the mortality from gun-shot wounds and injuries was enormously decreased.

Radiology and Treatment of Disease.

As a further development of the application of radiology—X rays and radium—many diseases have been submitted to treatment by both X rays and radium for their cure. For example, "rodent ulcer" or basal-celled carcinoma, is thought by many to be amenable to cure when treated by the application of X rays. Other diseases have also been treated radiologically, especially some forms of new growth. In certain cases good results have been obtained, but at the present time it is difficult to dogmatise what is the true and permanent value of X rays and radium in the treatment and cure of disease, especially malignant disease.

Conclusion.

From the short account which I have been able to give you of the progress of surgery from Hunter's day to ours, it will be seen that the actual technique employed in the performance of surgical operations and the results which can be obtained thereby have reached a very high stage of perfection. It does not appear to me that we can expect in the future such great progress to be made in the details of the performance of operations themselves and the amelioration of the discomforts directly resulting therefrom. In my opinion the main lines of advance of surgery in the future will be along biochemical and biophysical lines both as regards diagnosis and treatment. If this assumption be correct it is essential that the medical student and the medical practitioner of the future should pay increased attention to all biochemical and biophysical problems—both in normal and diseased conditions.

Owing to the length of the curriculum and the multiplicity of subjects which the student of medicine of the present day has to pass through, there is a tendency for parts of the curriculum to be forgotten after the examination in it has been passed. Consequently the application of physiology in the investigation of disease is too often neglected and a student thereby is encouraged to acquire surgical knowledge —especially diagnosis—in a somewhat empirical manner. At the present time, however, there is a tendency in every modern school of medicine to give courses of "applied physiology and applied anatomy" during the later and clinical part of a student's educational career.

A NOTE ON JOHN HUNTER'S CARDIAC INFARCT.

By JOHN A. RYLE, M.D., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL.

In a recent communication to THE LANCET[1] Dr. J. Parkinson and Dr. D. Evan Bedford have reported their experience and reviewed the literature of cardiac infarction and coronary thrombosis. By their careful and extensive survey of cases and pathological material they have amplified the work of other observers, establishing and defining the syndrome which characterises this grave vascular accident, and indicating its relationships with angina

[1] THE LANCET, Jan. 7th, 1928, p. 4.

pectoris. They have shown that the status anginosus generally proclaims a coronary occlusion and that, notwithstanding the gravity of the event and its high immediate mortality, survival is common and a return to a life of modified or even full activity not impossible. From the descriptions of anginal cases left to us by the great masters, including Latham, Osler, Clifford Allbutt, and Mackenzie, it is now possible to select indubitable examples of seizures due to this cause. It is noteworthy that Heberden himself mentioned a few cases in which the pain persisted for hours or days.

My own interest in the subject was first stirred on reading a paper by J. W. McNee.[2] A natural curiosity concerning the history of a clinical syndrome which has only lately been accorded accurate portraiture, but which must in fact be at least as old as arterial disease, has since been quickened by a personal experience of several cases and by a recent discussion at the Medical Section of the Royal Society of Medicine (Jan. 24th, 1928). Recollecting the minuteness of the clinical detail in Sir Everard Home's account of Hunter's illnesses I have carefully re-examined the narrative of these and particularly of his alarming vascular crises. The story of Hunter's angina, of his foreboding that his death might be precipitated by anyone who should anger him, and of his actual demise in such a circumstance, is common property, and has found its place in the text-books and been recounted to generations of students. It is not, I believe, so widely recognised that his very first seizure was, in all probability, due to a coronary thrombosis; that he survived it for 20 years; and that, on examination after death, two fibrotic scars were found in the wall of his heart.

The descriptions which follow are drawn from Joseph Adams's "Memoirs of the Life and Doctrines of the late John Hunter, Esq." (London, 1817), in which the author includes full quotations from Sir Everard Home's Life. Sir Everard Home's account was based on observations of his symptoms noted by Hunter himself at the time of their occurrence or dictated to Sir Everard Home when he was too ill to write. I have italicised some of the more apposite passages.

"In the spring of 1769, in his forty-first year, he had a regular fit of the gout, which returned the three following springs, but not in the fourth; and in the spring of 1773, having met with something which very forcible affected his mind, he was attacked, at ten o'clock in the forenoon, with a pain in the stomach, about the pylorus: it was the sensation peculiar to those parts, and became so violent, that he tried change of position to procure ease; he sat down, then walked, laid himself down on the carpet, then upon chairs, but could find no relief. He took a spoonful of tincture of rhubarb with 30 drops of laudanum, without the smallest benefit. While he was walking about the room, he cast his eyes on the looking-glass, and observed his countenance to be pale, his lips white, giving the appearance of a dead man: this alarmed him, and led him to feel for his pulse; but he found none in either arm. He now thought his complaint serious. Several physicians of his acquaintance were then sent for: Dr. William Hunter, Sir George Baker, Dr. Huck Saunders, and Sir William Fordyce, all came, but could find no pulse; the pain still continued, and he found himself at times not breathing. Being afraid of death soon taking place if he did not breathe, he produced the voluntary act of breathing, by working his lungs by the power of the will; the sensitive principle, with all its effects on the machine, not being in the least affected by the complaint. In this state he continued for three quarters of an hour, in which time frequent attempts were made to feel the pulse, but in vain; however, at last, the pain lessened, and the pulse returned, although at first but faintly, and the involuntary breathing began to take place. While in this state, he took Madeira, brandy, ginger, etc., but did not believe them of any service, as the return of health was very gradual; in two hours he was perfectly recovered."

Hunter was aged 45 at this time. The restlessness which he showed in the attack is now known, in contradistinction to the rigid immobility of ordinary angina, to be a not uncommon feature of coronary thrombosis. The reference of pain to the epigastrium is also a recognised feature and may sometimes lead to a faulty diagnosis of acute abdominal disease.

[2] Quarterly Journal of Medicine, 1925–26, xix., 44.

Writing a hundred years ago Joseph Adams was sage enough to argue, and in opposition to Hunter's own idea, that, although the pain was apparently in the stomach, the actual seat of it was in the heart.

"That the disease was in the heart can now admit of no doubt: the cessation of the pulse is what might be expected from violent inflammation, as will be hereafter explained; *but the strongest proof that the heart at that time suffered an alteration in its structure, the effect of inflammation, is, that for the remainder of his life the patient suffered all the effects of angina pectoris. . . .*"

In 1776 Hunter had a serious illness in which vertigo and sickness played a prominent part. In 1785 he had another serious illness.

"About the beginning of April, 1785, (Sir Everard Home informs us) he was attacked with a spasmodic complaint, which at first was slight, but became afterwards very violent, and terminated in a fit of the gout in the ball of the great toe; this, like his other attacks, was brought on by anxiety of mind. The first symptom was a sensation of the muscles of the nose being in action; but whether they really were, or not, he was never able to determine. This sensation returned at intervals for about a fortnight, attended with an unpleasant sensation in the left side of the face, lower jaw, and throat, which seemed to extend into the head on that side, and down the left arm, as low as the ball of the thumb, where it terminated all at once: these sensations were not constant, but returned at irregular times; they became soon more violent, attacking the head, face, and both sides of the lower jaw, giving the idea that the face was swelled, particularly the cheeks, and sometimes slightly affected the right arm. After they had continued for a fortnight, they extended to the sternum, producing the same disagreeable sensations there, and giving the feel of the sternum being drawn backwards toward the spine, as well as that of oppression in breathing, although the action of breathing was attended with no real difficulty: at these times the heart seemed to miss a stroke; and upon feeling the pulse, the artery was very much contracted, often hardly to be felt, and every now and then the pulse was entirely stopt. He was afterwards attacked with a pain in the back, about that part where the œsophagus passes through the diaphragm, the sensation being that of something scalding hot passing down the œsophagus. He was next seized with a pain in the region of the heart itself; and last of all, with a sensation in the left side, nearly in the seat of the great end of the stomach, attended with considerable eructations of wind from that viscus: these seemed to be rather spasmodic than a simple discharge of wind, a kind of mixture of hiccough and eructation, which last symptoms did not accompany the former, but came on by themselves. In every attack there was a raw sore feel, as if the fauces were excoriated. All these succeeding symptoms (those in the stomach and nose only excepted) were in addition to the first, for every attack began with the first symptoms. The complaint appeared to be in the vascular system, for the larger arteries were sensibly contracted, and sore to the touch, as far as they could be touched, principally in the left arm; the urine at those times was in general very pale.

These symptoms increased in violence at every return, and the attack which was the most violent, came on one morning about the end of April, and lasted about two hours. It began as the others had done, but having continued about an hour, the pain became excruciating at the apex of the heart; the throat was so sore as not to allow of an attempt to swallow any thing, and the left arm could not bear to be touched, the least pressure upon it giving pain; the sensation at the apex of the heart was that of burning or scorching, which, by its violence, quite exhausted him, and he sunk into a swoon or doze, which lasted about ten minutes, after which he started up, without the least recollection of what had passed, or of his preceding illness. I was with him during the whole of this attack, and never saw any thing equal to the agonies he suffered; and when he fainted away, I thought him dead, as the pain did not seem to abate, but to carry him off, having first previously exhausted him.

He then fell asleep for half an hour, and awoke with a confusion in his head, and a faint recollection of something like a delirium; this went off in a few days.

The affections above described were, in the beginning, readily brought on by exercise; and he even conceived, that if he had continued at rest, they would not have come on: but they at last seized him when lying in bed, and in his sleep, so as to awaken him. Affections of the mind also brought them on; but cooly thinking or reasoning did not appear to have that effect. While these complaints were upon him, his face was pale, and had a contracted appearance, making him look thinner than ordinary; and after they went off, his colour returned, and his face recovered its natural appearance."

This description clearly refers to a further series of vascular storms of a critical kind. May they possibly

have accompanied a second coronary thrombosis? This illness laid him low from the beginning of April until the latter part of May, and ended with an attack of gout. After it he remained more than ever subject to the angina of effort or emotion.

In 1789 he suffered a loss of memory and more vertigo. Between 1791 and 1793 his anginal attacks became increasingly frequent and more prolonged, and arrived for lesser causes.

"On the 16th of October, 1793, when in his usual state of health, he went to St. George's Hospital, and meeting with some things which irritated his mind, and not being perfectly master of the circumstances, he withheld his sentiments; in which state of restraint he went into the next room, and turning round to Dr. Robinson, one of the physicians of the hospital, he gave a deep groan, and dropt down dead!"

The body was examined after death and the findings in regard to the heart were reported as follows:—

"The pericardium was very unusually thickened, which did not allow it to collapse upon being opened; the quantity of water contained in it was scarcely more than is frequently met with, although it might probably exceed that which occurs in the most healthy state of these parts. The heart itself was very small, appearing too little for the cavity in which it lay, and did not give the idea of its being the effect of an unusual degree of contraction, but more of its having shrunk in its size. *Upon the under surface of the left auricle and ventricle, there were two spaces nearly an inch and half square, which were of a white colour, with an opaque appearance, and entirely distinct from the general surface of the heart: these two spaces were covered by an exudation of coagulating lymph, which at some former period had been the result of inflammation there.* The muscular structure of the heart was paler and looser in its texture than the other muscles in the body. There were no coagula in any of its cavities. The coronary arteries had their branches which ramify through the substance of the heart in the state of bony tubes, which were with difficulty divided by the knife, and their transverse sections did not collapse, but remained open. . . . The semilunar valves of the aorta had lost their natural pliancy, the previous stage to becoming bone, and in several spots there were evident ossifications. The aorta, immediately beyond the semilunar valves, had its cavity larger than usual, putting on the appearance of an incipient aneurism: this unusual dilatation extended for some way along the ascending aorta, but did not reach so far as the common trunk of the axillary and carotid artery. The increase of capacity of the artery might be about one-third of its natural area; and the internal membrane of this part had lost entirely the natural polish, and was studded over with opaque white spots, raised higher than the general surface. . . ."

To this account Joseph Adams added the following commentary:—

"The opake spot in the heart was probably formed during the severe illness of 1773, at which time the heart refused to act, the invariable consequence of high inflammation in a muscular part. Such is the immediate effect during the severe paroxysm of inflammation in the heart. The consequences for the remainder of life must depend on the alteration, if any, which had taken place from the inflammation. Sometimes the heart never recovers, and the circulation is carried on feebly till the patient expires, without any external cause: sometimes the heart is dilated by the afflux of blood on which it is at first unable to contract, and after a time contracts with irregularity, from an incapacity to acquire its original form. In Mr. Hunter's case, from an alteration in its texture, its actions became irregular; and consequently the action of the lungs. This constitutes angina pectoris, with which, Sir Everard Home informs us, Mr. Hunter was afflicted for the last 20 years of his life, the exact period of this illness."

If it be accepted—and it is difficult to offer any alternative explanation—that Hunter's first seizure was due to a cardiac infarction, it is surely a most remarkable feature of his case that he should not only have survived it for 20 years, but that for the greater part of that time he should have been able to devote himself to labours which continued to add lustre to his earlier fame. This chapter of Hunter's life which is concerned with his illnesses affords us a glimpse of the great strength of will and the scientific interest with which he constantly met them, and only serves to increase our admiration of the man. I do not know whether any parallel case can be quoted, but for the benefit of the physician faced with the delicate task of prognosis in this grave and disturbing malady it is at least gratifying to record that it may sometimes be consistent with long years of useful activity.

An Address
ON
VOLUNTARY HOSPITALS AND PUBLIC AUTHORITIES.*

BY SIR WILLIAM HAMER, M.D. CAMB., F.R.C.P. LOND.,
LATE MEDICAL OFFICER OF HEALTH FOR THE COUNTY OF LONDON

THE conception that coördinated effort is needed for furthering the health interests of communities is a comparatively modern one. Simon, in his "English Sanitary Institutions," in tracing the rise and early progress of British preventive medicine, insisted that it was the development of "a larger sympathy of man with man" that really marked, more than a century and a half ago, the turning-point in the history of the human race. This growth of the "new humanity" was favoured

"by two separate and dissimilar (though often coöperating) influences, one dating from the second quarter of the eighteenth century and one dating from the fourth, the former expressly religious . . . the latter essentially an outcome of stimulated political reflection. . . . Throughout the centennium, 1738–1838, the tide of religious philanthropy was ever on the rise, ever gaining more and more social influence."

Then at the close of that period there came "a rush to final success," culminating first in the Act of 1834, which,

"through the good luck that Mr. Edwin Chadwick was made the secretary of the New Poor Board, gave occasion a few years later, to a beginning of public sanitary inquiry in Great Britain";

and, secondly, in the Act, under which it first became possible to bring to light record of life and death in this country. Simon adds the significant note that "while the interests of the public health were frequently under discussion in Parliament, the growth of unofficial knowledge and sympathy in relation to the movement was shown by the rise of voluntary associations." Later, Sir John pays tribute to the work done, from the beginning of the 'seventies onwards, by the Charity Organisation Society, "strenuously endeavouring to educate the public towards a better economy of charitable resources." It is most intriguing, at the present juncture, to study the attempts made, in the third quarter of the last century, to substitute organised system for haphazard methods in dealing with the health of the community. We read in Simon's book of the determined fight made by Lord Shaftesbury, Chadwick, Southwood Smith and others to make the General Board of Health a success, and of the opposition of the "interests," and we are reminded that there was also "interest" which in those early 'fifties had raised its voice—that "of the millions of population still under the free ravages of infectious disease." Chadwick bore the brunt of the attack; he was declared to have been "impatient" but, as Simon says, "patience under sufferings of one's own, and patience toward the sufferings of others, are not equal measures of magnanimity." Chadwick had knowledge, at first hand, of the human miseries which were accruing

"day by day under the almost universal prevalence of sanitary neglect; and the indignation, which he was entitled to feel at the spectacle of so much needless suffering, is not ignoble excuse for such signs of over-eagerness as he may have shown."

Those two great friends of progress—the voluntary and official organisations—set to work with a will, and the results which have floated up, in the last century, would have surprised the pioneers. Dr. Farr's statement of 1857, that "the deaths of 17 persons per 1000 may be considered, in our present imperfect state, natural deaths," but that "this standard

* An address delivered on Feb. 13th at a meeting of the Charity Organisation Society.

cannot be applied to the large towns, which can never become so healthy as the country," is an interesting one, in view of the fact that the average death-rate in London, for the last seven years, has been 12·3. Even more remarkable is the reduction, since 1900, in infant mortality, which must, however, be regarded in the main as an outcome of the Education Act of 1870.

The successes gained obviously suggested that the humanitarian, sanitary or preventive idea, call it what you will, already so advantageously exploited in public health, must now be turned to use also in personal health, and plainly the attack had to be directed against the beginnings of disease. Hence, school medical work was undertaken nearly 20 years ago, maternity and child welfare work commenced a little later and has been in active operation since 1918, tuberculosis work began in 1911, and venereal disease clinics came into operation in 1916. The passing of the National Insurance Act and the establishment of the above-named public health services made it clear, as Lord Dawson told us at the time, that

> the line of demarcation, between State medicine in a locality and domiciliary medicine, as represented by general practitioners, was no longer that between preventive and curative medicine";

and he and others set to work to devise plans "under which institutional and organised provision should lead off directly from private practice." And now, with the Ministry of Health proposals, a further great opportunity presents itself, and voluntary hospital committees for some time past have been actively engaged in considering how they can give help in realising the new ideals.

The Voluntary Hospital as a Consultative Centre.

In a presidential address at Norwich on the Junction of the Voluntary Hospital in Relation to Public Health Services, Sir Arthur Stanley described how, "by giving of their best," the medical profession had

> altered the character of the voluntary hospitals, until from being merely dispensers of charity they have become the main centres of training and research . . . they have not set their helm by any fixed star, nor steered their course by any official chart," and "this was not so much of importance while the State in respect of its public health responsibilities was content to be driven by circumstances rather than guided by principles. It is obvious, however, that, when one of the factors in this situation underwent a change, the other could not fail to be affected." He adds: "It will be appreciated at once that all the essential elements which are constituent parts of a complete public health service on behalf of the sick, are in greater or less degree in existence; they do not call for creation, they call for adjustment, correlation, and development. This is obviously the object for which we should all strive, and in the attainment of this it is obvious that the voluntary hospitals can and must play an important part."

Sir Arthur Stanley then refers to the questions upon which the Minister of Health asked, a year ago, for suggestions. He points out that complete uniformity of practice may not be attainable, but he thinks it desirable to consider to what extent it might be wise to formulate general principles for guidance. A principle which must, he says, be kept in view is that of "establishing the voluntary hospitals in the position which they have as yet only partially attained namely, that of consultative centres." The Minister raised the question of the possibility of allocating categories of cases to one or other type of hospital. As things stand, some types are already absent, even from the largest voluntary hospitals—e.g., maternity cases, infectious fevers, mental cases, and other specialised types; and reasonable discrimination might clearly continue to be exercised, without any prejudice to teaching functions. The all-important point is, that sight must not be lost of the great advantages to all concerned to be gained from the careful framing, by local consultative committees on which the representatives of the voluntary hospitals and the public authorities would confer together, of schemes for giving effect to the eminently practical objects adumbrated in the Minister's letter.

Two examples may be cited of things already accomplished by coördinated effort on the part of health workers. The London mortality from measles up to the fifth year of age per 1000 born has in the last five years, as compared with the preceding quinquennium, declined more than 25 per cent.; this notable result is clearly ascribable to coöperation between the Ministry, the Metropolitan Asylums Board, the county, city, and borough councils, and medical practitioners. Again, having regard to the advanced state of evolution of the voluntary hospitals and the social services already rendered by them through their almoners' departments, it was recognised at the outset that the London school medical service must be developed on similar lines. It was therefore devised to work as a hospital and general practitioners' service, coördinating the activities of doctors and social workers, and linking them up with the general education service of the Council, and not as a newly constituted ad hoc municipal service. An important outcome of this decision has been that the wishes of the hospitals, as expressed by Sir William Collins,[1] were substantially met; moreover, general practitioners have, during the last 18 or 20 years, had the opportunity of becoming keenly interested in school medical work. It is confidently hoped, therefore, that the precedents thus established may help in securing, in further developments, that coöperation between unofficial and official activities which is so much to be desired.

All those who have studied the question of medical out-relief have been impressed with difficulties arising from application of differing methods of practice in similar and closely adjoining areas. The problem has in the past been mainly concerned with curative treatment; it now becomes more complex, for not only those who are, or believe themselves to be, seriously ill, are in question; there is the clamant need of endeavouring to withstand the beginnings of disease. Dr. Gee used to say that "in medicine the first thing is diagnosis, and the second thing is diagnosis, and the third thing is diagnosis." Appreciation of the truth of this led the guardians in North Lambeth many years ago to place the entire poor-law medical service, institutional and out-relief, under unified control. It is not only the patients claiming hospital treatment who make up the sum total of those for whom such treatment may be deemed desirable. McVail[2] gave a number of typical instances of "cases which ought to be removed" and "cases which ought not to be removed." Already, in 1909, he had noted that—

> "in the cities persons were being attracted to institutions who were able to maintain themselves." He added, "repression of those who do not need and so do not deserve . . . will be even a more difficult duty than attraction of the needy and deserving who at present refuse to come in."

Now that the importance of exercising discrimination, as between hospital and home treatment, is seen to be of more vital moment than ever before (from the point of view of the community as well as of the patient), the experience gained in Lambeth is especially important.

The results already achieved by the educated mother who has been through the schools, when compared with those aforetime attained by the illiterate mother, of the out-patient rooms of half a century ago, represent a net gain of 60 per cent.—i.e., a reduction of infant mortality from about 165 per 1000 born to about 65 per 1000 born. Thought and care, such as have been devoted in the last 30 or 40 years to promoting the welfare, first of school-children and then later of infants, should now be further directed to the provision of carefully coördinated medical help, for all ages and both sexes, on preventive and curative lines. Such an

[1] Hospitals and the State, a paper read in 1912 at Birmingham, at the Third Annual Conference of the British Hospitals Association.

[2] Appendix XIV., Report of Royal Commission, 1909, pp. 113–116 and 156.

enterprise must be a coördinated undertaking of all available voluntary and official organisations in each locality; there is work and enough for all; competition, therefore, between voluntary and official institutions can, and should, be avoided. Each voluntary hospital in London, as consultative and teaching centre, should form a nucleus functioning in close coöperation with associated health agencies. In the living organism formed by aggregation of such units there must be no schism of foot against hand, or of ear against eye, "each member should have the same care, one for another." Governed not so much by binding covenants as by the inspiration of a common purpose, such an organisation would speedily bring about a fall in death and sickness rates, and a rise in efficiency and working capacity that would open the eyes of the statisticians.

TREATMENT OF BURNS BY TANNIC ACID.

By R. M. GORDON, *D.F.C.*, M.B. Glasg.,
LATE HOUSE SURGEON, HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET, LONDON.

Burns are most worrying and unsatisfactory lesions, both in hospital and in private practice. The extreme prostration associated with the initial stage, the developing toxæmia, the local condition, and the end-result, all in turn give cause for serious thought and consideration. The mortality-rate is still very high. Woodward and Drummond [1] find a rate of 54 per cent. for burns and a rate of 25 per cent. for scalds. Fraser [2] groups them together at 38·7 per cent. in children of 10 years and under. Improved technique and progress in medicine have helped to reduce this figure, but it is still very alarming.

Avoidance of Toxæmia.

The treatment for primary shock is fairly uniform. The uses of the electric cage, transfusions, and infusions, and drug treatment have been well discussed in modern text-books. It is in the treatment of the local condition that methods vary considerably. If a sound and simple means of preventing the toxæmia which follows the burn could be found a great step in the right direction would have been taken and a happier outlook could be entertained. About 60 per cent. of the deaths occur, it is stated, from shock within the first 48 hours. Toxæmia should be included as an early factor, for it is known to be active within this time. Robertson and Boyd [3] found it within eight hours in their experiments on animals.

There is one method which efficiently combats the onset of toxæmia, but which is little used in this country. That is the use of tannic acid, first advocated by Davidson,[4] of the Henry Ford Hospital, Chicago, in 1925. Aqueous solutions, in a strength of about 2 per cent., applied to a burned surface for 24–48 hours produce a coagulum containing the degenerated and broken-down tissues. The surface is actually tanned. As the absorption of the toxins is prevented by precipitation the toxæmia does not develop. That the constitutional reaction following the burn is due to the absorption of toxins is generally admitted. Many interesting observations have been made to support this conclusion. Pfeiffer [5] isolated the products of protein decomposition in burns and grouped them as neurotoxic and necrotoxic. Post-mortem appearances in burns were found to be comparable with the changes seen in other cases where a high degree of infection had been present, as in septicæmia. Markusfeld and Steinheus [6] showed that, if the blood-supply to the burned area was cut off, the usual constitutional reaction did not take place. Vogt,[8] by performing parabiosis between two animals and burning one, found that both were equally affected, though not so severely as under ordinary circumstances. If they were separated within 12 hours the unburned animal exhibited only a slight degree of toxæmia. Vogt, Robertson, and Boyd, and oth found that the toxæmia was only of a mild degre the injured tissues were removed soon after accident and the wound treated aseptically. T radical treatment of burns would be to remove the affected tissues, as their presence is the cause the toxæmia. In débridement the whole burn a is excised and a clean raw surface left behind. I a sound procedure, but has its disadvantages. thoroughly carried out it means a long anæsthetic a critical time, the discarding of islands of epithe tissue, and great risk of subsequent infection, besi a painful after-treatment and the necessity for sk grafting. In severe cases débridement could not attempted in the first instance, but tempor measures would have to be employed until patient's condition justified the risk of an anæsthe Exsanguination transfusion as an adjunct has gi excellent results where delay has resulted in development of toxæmia.

Other methods aim at the control of the format and absorption of toxic products and the prevent of sepsis. Picric acid is still widely used in this coun It precipitates proteins to a certain extent and weak antiseptic properties. Thierry and other Fre surgeons first advocated its use as a dressing. T its precipitating properties are practically negligi is well illustrated by the results obtained with Paraffin preparations are also employed to a gr extent. Their usefulness is questionable if sepsi present, or if the area has not been thoroughly clean beforehand. Absolute alcohol and full exposure w the application of a drying powder have b employed with the object of drying up the surf and thus impeding the formation of the autol products and lessening the risk of sepsis. The tr ment is difficult to carry out satisfactorily.

Burns Successfully Treated with Tannic Acid.

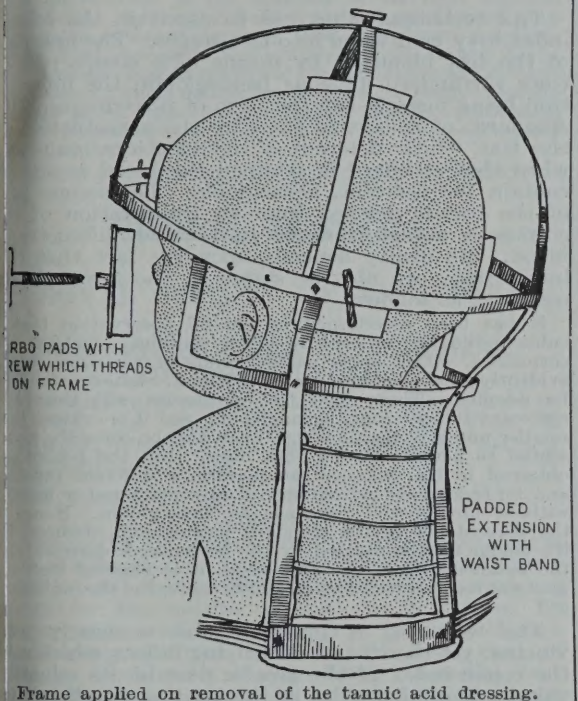
The use of tannic acid simplifies the treatment a great extent. The application is soothing quickly relieves pain. The coagulum forms a h protective covering for the tissues beneath and whole area is perfectly dry, so the loss of body fl is minimised. Scar formation is lessened, owing to absence of sepsis, and the wounds heal quic Above all the toxæmia is controlled, and m efficiently the earlier the tannic acid is appl Davidson's technique was as follows. The pat having been given a sedative, sterile gauze pads w bandaged over the burn and this dressing soake 2·5 per cent. aqueous solution of freshly prep tannic acid. Within 24 to 48 hours the tissues w stained a light brown colour. The dressing was t removed and the whole area exposed freely to the

The procedure in the following case of se scalding was somewhat modified, but serves as example of the effectiveness of tannic acid.

The patient, a girl aged 2, was admitted to the G Ormond-street Hospital under the care of Mr. G. E. Wa on the evening of Nov. 14th, 1926. She was suffering f severe shock. Vesication was present over the w scalp, over the brow, and down in front of both ears to neck. The whole of the neck posteriorly, the left shoul and the flexor surface of the left elbow-joint were simil affected. A dirty rag dipped in olive oil had served dressing. She had had bronchitis recently and there v still signs of it in the chest. As the scald was very d it was decided to clean it up before applying the tannic a The next morning her condition had improved somew and she was given a light anæsthetic of ether and oxy The skin was first cleansed with ether soap and the l tissues removed with a razor, the blade being held at r angles to the surface. It was then swabbed with abso alcohol and strips of gauze, dipped in the freshly prep 2 per cent. solution of tannic acid, were laid over the surf The whole was then bound loosely in gauze bandages the child taken back to the ward after ten minutes' a thetic. The dressing was kept moist by sprinkling frequently with the solution.

A cage was devised whereby a considerable amount of weight of the head and shoulders would be borne by a w band, the rest by pads over the scalp. With this the pro tive coagulum could be exposed, the head kept at rest, at the same time protected from trauma, as shown in

ustration. The cage was applied on the third day. By the venth day the coagulum was quite loose on the underlying rface. Pus was present at one point where a wound, as ll as the scald, had previously been noticed. The coagulum as all removed on the eighth day, exposing a clean healing rface beneath, the infected area being quite localised. A essing of ambrine with a thick covering of gauze was plied for 48 hours, the child resting on this "cushion" steriorly. The whole was then fomented for 24 hours. ter this it was treated with flavine and oil for a few days, d then this dressing was replaced by equal parts of sterile seline and ung. boracis. Thereafter the wound healed



Frame applied on removal of the tannic acid dressing.

interruptedly. The pressure of the pads on the cage had sulted in a deeper destruction of the underlying tissues d interference with the local regeneration, but the areas volved were small and the disadvantage was adequately unterbalanced by the efficient protection given to the rest the scald. These areas healed quickly without sepsis when e cage was removed.

On the ninth day of the illness the child developed broncho-neumonia and recovery seemed unlikely for the three llowing days. The wound, however, remained clean, xcept the part where pus had previously been present. he had fully recovered by then from a mild toxæmia which id been present during the first day or two. After these w days of anxiety the chest cleared quickly and the child as up and running about the ward ten days later. There now a growth of fine fluffy hair over about two-thirds of e surface of the scalp.

There has been little written reference in this untry to the use of tannic acid in the treatment of urns, yet it is simple and efficient and deserves a ore generalised use. This child was so severely alded that any hope of recovery seemed remote. et, in spite of the presence of bronchitis and the ter development of broncho-pneumonia, she did cover, and tannic acid was probably the means of ving her life, by controlling the developing toxæmia fore it had advanced very far. She took fluids well id never vomited, which emphasised the fact that xæmia was at its minimum. The tannic acid ressing was soothing and the treatment easy to carry it. The loss of body fluids was minimised by the tringency of the tannic acid; the surface of the ound remained perfectly dry until the healing rocesess had loosened the coagulum. The removal of e coagulum at this stage seems advantageous, as it rmits free examination of the area and the exposure a moist granulating surface. The coagulum, when rmed, protects the tissues from trauma and exposure. gain the after-treatment is simplified because sepsis is absent. Sepsis did occur at one point, but this was due to a wound, down to bone, caused by the original accident. It is interesting to note that this sepsis remained quite localised, as the tannin shut it off from the surrounding tissues. The wound healed quickly and scar formation was much less than was expected.

I am indebted to Mr. Waugh for his permission to publish the case.

Clinical and Laboratory Notes.

ON THE PROTEAN NATURE OF "INFLUENZA."

A REPORT OF A MILD EPIDEMIC AT SEA.

BY R. G. R. WEST, M.B., M.R.C.P. LOND., D.P.H.,
NUNEATON.

THE interesting features of this epidemic were the varying symptomatology and the long latent period preceding the first case of typical influenza. Unfortunately no bacteriological investigation was possible, but it seems probable that someone, probably a member of the crew, had boarded the ship in London carrying an organism which produced epigastric pain and vomiting in Case 1; spasmodic cough in Cases 2, 3, and 4; bronchial catarrh in Case 5; acute tonsillitis in Case 7, and, after ten days' incubation, typical influenza in Case 8.

On August 7th, 1927, a liner left London with a crew of 100 and about half that complement of passengers, bound for South America. On the first night at sea one of the crew complained of acute epigastric pain with vomiting. He had had a sore-throat on the previous day. There was some catarrh of the pharynx, and the tonsils were swollen. The pulse-rate was 100 and the temperature 98·2° F. No abdominal signs were elicited. There was no headache and no myalgia, and the patient's condition improved on the following morning. He appeared to have recovered in two days' time (Case 1). Three men attended the ship's surgery during the following two days with spasmodic coughs (Cases 2, 3, and 4). Only one had a sore-throat. In the two subsequent days another two seamen reported sick. One had a mild bronchial catarrh (Case 5), the other slight pharyngitis with cough (Case 6).

During the following week occasional cases similar to the above, with a spasmodic dry cough as their most prominent feature, presented themselves at the rate of about one new case a day. No other illness was reported, and no man was off duty during this period. Eight days out from London an acute tonsillitis occurred in a man subject to such attacks (Case 7). It was not until the tenth day at sea that a case of typical influenza occurred among those on board. A quartermaster (Case 8) came to me looking thoroughly ill. He complained of severe frontal headache, pains in the neck, aching in the limbs, and sore-throat. His temperature was 102° F. and his pulse-rate 100. In three days he was well enough to return to duty, though the usual post-influenza lassitude remained for some days longer.

In the subsequent week two further cases of typical influenza occurred, one in an engineer and one in a scullion, occupations which would keep the two men quite out of contact with each other or with the quartermaster. In addition, several men from all departments attended for various degrees of cold in the head and cough. At the end of the week two cases occurred, one quite unlike any influenza I have seen, the other providing a link with the previous cases. The former was a man seized with spasmodic abdominal pain in bouts of half a minute's duration every five

to ten minutes. There was almost dysenteric diarrhœa and some collapse. The temperature was 98·4° F., the pulse-rate 110. The tongue was clean. The whole abdomen was at first so rigid as to suggest an abdominal emergency. There was tenderness in the right iliac fossa. In two days the man was well again, except for lassitude, which continued for several days. The second case was a boy of 19, who, after an initial rigor, collapsed one morning with diarrhœa and vomiting. This lasted a few hours only, and was followed by pain in the right side of the chest, with a small area of pleural friction. I saw him at this stage, when he looked thoroughly "toxic"; temperature, 100·1° F.; pulse-rate, 110; respirations, 20. No further signs developed except severe headaches on the second and third day. He informed me later that he had coughed up blood-stained sputum three times at the onset of his illness. He was in bed for five days, picked up again very slowly, and retained signs in the upper lobe of his right lung, which, together with his initial hæmoptysis, made me doubt the cause of his pleurisy. A month later, however, no added sounds could be detected in the lungs; slight impairment of percussion note alone remained. During the remaining week of the voyage acute catarrhal conditions of the upper respiratory tract were rife among the passengers, officers, and crew. Some were mere "colds" without fever. In some mild tonsillitis with a spasmodic feverish cold occurred. In two cases marked laryngitis was the chief feature. In several there was some huskiness. Sporadic cases of diarrhœa occurred here and there, but this is, of course, a common condition in ships traversing tropical waters.

The influenza cold ran its course through the ship, cases occurring at intervals during the 24 days of the outward voyage and during a subsequent fortnight in dock in Buenos Aires, and ended with one or two sore-throats, and one moderately severe laryngitis during the first few days of the homeward voyage. No one was affected twice, except a sailor with large ragged tonsils, who had two attacks of acute tonsillitis, with three weeks' interval between.

A CASE OF
SUBACUTE COMBINED SCLEROSIS OF THE CORD OF SUDDEN ONSET.

BY S. C. H. WORSELDINE, M.R.C.S. ENG.,
CAPTAIN, INDIAN MEDICAL SERVICE.

THE following case seems worthy of record:—

A native driver in a mule corps, aged 25, was admitted to the Indian Military Hospital, Maymyo, suffering from loss of use of both legs, due, in his opinion, to witchcraft in his village in the Northern Punjab. He stated that he had never been in hospital before, and denied venereal disease. Seven days previously he had noticed weakness in his legs after the day's work; this weakness had steadily progressed until on the seventh morning he had been unable to stand up. No history of any pain or peripheral sensations could be elicited, nor any history of trauma.

Condition on Examination.—Patient appears to be a muscular, fit man. There is complete inability to move either leg from the hip downwards. Both legs are very spastic, and considerable force is required to flex the knees. Knee-jerks equal but exaggerated. Ankle-clonus present on both sides. Plantar reflex: Marked extensor bilaterally. Both eyes react to light and accommodation. Pupils equal and normal size. No nystagmus.

Sensations.—Pain: diminished over both legs, and an area extending from the pubes to 2 inches above the umbilicus. An area of hyperæsthesia from this to the xiphisternum. Sensations of touch, deep pressure, heat and cold lost to legs and area below umbilicus. Diminished sensation on rectal examination. No abnormality in urine, heart, and lungs, optic discs or retinæ. Spleen not palpable. Wassermann reaction negative. Cerebro-spinal fluid: not under pressure, clear, with normal cell count.

Blood examination: Total red cells, 2,340,000 per c.mm.; hæmoglobin, 80 per cent.; colour-index, 1·7. Poikilocytosis and anisocytosis present. Normoblasts and megaloblasts present; no myelocytes seen; 5 per cent. eosinophilia.

Diagnosis and Progress.—A diagnosis of subacute combined degeneration of the cord was made, although megaloblasts are rarely seen except in pernicious anæmia.

Two days after admission retention of urine developed. Fæces passed voluntarily. After a week in hospital the spasticity increased and there was loss of sensation to pain over the areas where it was previously diminished. A painless effusion of fl appeared in the left knee-joint.

The case could not be followed up, as he w invalided to his home.

A NOTE ON THE
FALLACY OF THE COLOUR-INDEX.

BY B. DERHAM, M.D., M.CH. R.U.I.,
LATE MEDICAL OFFICER OF HEALTH FOR GARSTANG.

THE technique employed to ascertain the colo index may be divided into two stages. The first p of the test identifies by means of a comparison tints a standard aqueous hæmoglobin, the infor tion being furnished in the form of percentages. standard, of course, is fixed by the perpetuation the tint which determines the identification; a when that standard is attained the blood is said contain 100 per cent. hæmoglobin. The second p of the test is derived from an enumeration of corpuscles actually present in 1 cubic millimetre blood. Its utility depends upon the fact that t information can also be stated in the form of p centages, as follows.

It has been ascertained by careful observation tha cubic millimetre of healthy blood contains 5,000,000 corpuscles, within fairly narrow limits of variation, wh evidently must exist in a case of this kind, whatever stand be adopted. These 5,000,000 corpuscles will thus represent 100 per cent. hæmoglobin; and it is evident t smaller numbers than 5,000,000 can also be correctly re sented as percentages on that basis. But the percent obtained in this manner can perform a different funct and be treated as percentages of abstract number mer without any special reference to hæmoglobin. Hence the percentages of the standard hæmoglobin obtained the colour test be divided by the percentages derived fr the enumeration of the corpuscles, it is claimed that quotient represents the hæmoglobin content of the individ cell.

The reasoning is plausible and seemingly c vincing, yet there is an underlying fallacy which r the colour-index of the greater part of its scient value. The fallacy lies in the tacit assumption t in the course of the attenuation of the hæmoglo of a corpuscle in anæmia the weight and volume water introduced into the cell are precisely equal the weight and volume of the hæmoglobin remov from the cell. This criticism is established by fact that (taking an extreme case) the colour-ind of 0·5 is interpreted to mean that one-half of attenuated cell is normal hæmoglobin and the ot half water. Now since we begin the process attenuation with a normal hæmoglobin of colo index unity, and end with an attenuated hæmoglo of colour-index 0·5, and since no other factor t the addition of water intervenes, it is evid that the underlying assumption is that the wa exactly replaces the hæmoglobin in the constituti of the cell, weight for weight and volume for volume in other words, that the specific gravity of the wa is identical with that of the hæmoglobin which replaces in the cell.

This is the fundamental fallacy of the curr theory of the colour-index, because the specific gravi of normal hæmoglobin is much greater than that water. Therefore if we attentively follow the proce of attenuation we will perceive that, weight weight, the volume of water introduced into the c would be much greater than the volume of hæm globin withdrawn from the cell, with the necessa consequence that there would be a very great a constantly accelerating augmentation of the to volume of the attenuating hæmoglobin far in exc of what is attributed to it by the current procedu

An Illustration.

I will now select a concrete case to illustrate so of the consequences of the fallacy which I ha indicated.

To begin with, a definition of hæmoglobin is required. healthy blood corpuscle is an almost chemically pure colloi

ution in water of what may be appropriately termed olute hæmoglobin, with the addition of small quantities other proteids, fats, &c., which constitute the stroma of corpuscles. The composition is given as water, 56·5 ts; absolute hæmoglobin, 41·1 parts, and other proteids, , &c., 2·4 parts. The specific gravity is ascertained to 1088. For purposes of calculation, I suggest that this uld be called "standard aqueous hæmoglobin." Next h regard to the serum of the blood. The addition of the s, proteids, &c., of the blood to water raises the specific vity from unity to 1030, subject to slight variations. ost the sole agent in raising the specific gravity of the od above 1030 is the addition of standard aqueous moglobin. A mixture of equal parts of standard aqueous moglobin of specific gravity 1088 and serum of specific vity 1030 represents the composition of healthy blood ich possess a specific gravity of 1058 and contains 5,000,000 puscles in 1 cubic millimetre. Also we can easily calculate m the given data that the specific gravity of standard eous hæmoglobin diluted with half its volume of water lour-index 0·5) is 1043.

Now for the illustration. A sample of blood is said to contain 50 per cent. or its equivalent of standard aqueous hæmoglobin possessing a colour-index of 0·5. With the aid of the data quoted we calculate that the specific gravity of blood containing 50 per cent. standard aqueous hæmoglobin or its equivalent is 1043. But we have just seen that 1043 is also the specific gravity of standard aqueous hæmoglobin diluted with one-half its volume of water. Then evidently that sample of blood must consist entirely of attenuated aqueous hæmoglobin of colour-index 0·5; and there would be no serum whatever. In other words, 10,000,000 corpuscles would be required to accommodate the attenuated hæmoglobin postulated by the data. I have discussed an extreme case in order better to demonstrate the fallacy of the colour-index; but this fallacy is present throughout the whole range of values, although in a minor degree in the earlier stages.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF NEUROLOGY AND OPHTHALMOLOGY.

AT a combined meeting of these Sections held on . 9th the chair was occupied by Prof. E. AMWELL, President of the Neurological Section, l a discussion on the

OCULAR COMPLICATIONS OF ENCEPHALITIS LETHARGICA

s opened by Dr. JAMES COLLIER, who said that the ue of a discussion in this difficult region lay chiefly the record of individual experiences. It was not ugh for the nature of cases to be proved by opsy, and, even so, when a gross lesion, such as a morrhage, occurred in a rapidly fatal case of hargic encephalitis it was likely that the true ure of the case might be missed. So far there l not been evolved any reliable clinical standard the disease; its manifestations were very varied. case well illustrating the difficulty was that of a n aged 56, who had had an attack of cerebral hilis. He was seized with vomiting and complete rexia lasting three weeks, during which time he s seen by six physicians, none of whom could find y nerve involvement. At the end of the fourth ek, when he was dying, the picture was typical of hargic encephalitis. Tumour of the brain with lopia and sleepiness coming on rapidly might, the absence of papillœdema and long-continued dache, simulate the disease under discussion, but frontal tumours did not cause the Parkinsonian drome. The latter might be simulated by lesions any nature in the upper part of the brain stem. ere generalised poliomyelitis might simulate ephalitis lethargica so exactly that they could y be differentiated by seeking for polymorpho-lear leucocytes in the cerebro-spinal fluid. Polio-elitis did not, however, seem to cause the Parkin-ian syndrome. The inflammatory lesions of the ease might involve any part of the nervous chanism subserving vision. In one typical case patient had had complete left homonymous mianopia when the coma had subsided, and it l remained four years. In another case the later ical stage had been dominated by the syndrome retrobulbar neuritis, and blindness had come on few hours, with loss of the light reflex. This had n replaced by a large central scotoma which had ished in six weeks; there had been no papill-ema. Dr. Collier had only seen one patient with ssive papillœdema, and in that case there had been retinal hæmorrhages. Two kinds of ocular alysis might be met in the disease: (1) That any of the peripheral oculo-motor nerve-trunks, ugh rarely more than one in a patient. It was suggested to be due to a heaping-up of lymphocytic inflammation at the peripheral origin of the affected nerve. Recovery from this always took place in encephalitis lethargica. (2) There might be a nuclear ophthalmoplegia—i.e., an irregular ophthalmoplegia, seldom complete, affecting both eyes and leaving the optic axes unparallel. The more severe degrees left a measure of permanent paralysis. He had not seen any paralysis of conjugate movement with the axes remaining parallel and no diplopia, probably because the disease spared the white matter to a considerable extent. Nystagmus was not a common accompaniment. Herpes had been reported with every known form of encephalitis, and occasionally it was met with in encephalitis lethargica. He had not seen it in that association, but he had met a number of cases with unilateral total internal ophthalmoplegia, probably caused by a herpetic lesion of the ciliary ganglion; no other signs of the disease, however, had been detected.

The Ophthalmologist's Point of View.

Mr. F. A. WILLIAMSON-NOBLE dealt with the subject from the ophthalmological standpoint. He spoke of Dr. Perdrau's recent work, and gave an account of the experimental work of Grüter, Levaditi, and Harvier. Among the eye lesions occurring as a sequel to encephalitis lethargica were jerky eye movements, lack of blinking, blepharoclonus, partial ptosis, unequal pupils, deficient accommodation, deficient convergence, nystagmoid jerkings, diplopia with squint, lid retraction, oculo-gyric crises, sluggish reaction to light, Argyll Robertson pupil, squint, flickering of lids on tapping globella, and the blinking sign. One of the commonest was loss of the power of convergence, occurring in the Parkinsonian syndrome, usually associated with slight inequality of pupils and poor reaction to light. Another common symptom was a twitching of the lids on voluntary closure of the eyes. At Queen-square Hospital there had been several cases with oculo-gyral crises, as described by Wimmer. They consisted of spasmodic attacks of conjugate deviation of the eyeballs, mostly vertical, or vertical and to the side, and were usually seen during fatigue. In some patients there was a strong emotional factor. These crises might endure only a few seconds or might last hours. One patient had had a strong suicidal tendency during the attack. Looked at generally, he thought optic disc changes could be regarded as a very rare complication in this disease, and he agreed with MacNalty that in diagnosing a condition of encephalitis lethargica the absence of optic neuritis was a valuable negative sign.

Dr. A. FEILING referred to the oculo-gyric crises which had, he believed, only been noted in this country during the last two years; the phenomenon illustrated the fact that the sequelæ of the disease varied with successive epidemics. None of the cases with oculo-gyric crises that he had seen were older than 30 years. There was a sudden forcible movement of the eyeballs upwards. It was not entirely tonic; in his cases the eyeballs had shown rapid

clonic movements. The attacks lasted any time up to half an hour; but one patient had reported an attack lasting eight hours. One of his cases had had a spasmodic movement of convergence of the eyes. In none had he been able to control the attacks. He agreed that papillœdema was very uncommon in acute encephalitis lethargica, in fact when that symptom was present he regarded it as a point against the diagnosis of the disease. A permanent paralysis of any of the external muscles of the eye was comparatively uncommon, but affections of intrinsic ocular muscles were common, chiefly a deficient contraction of the pupil on accommodation. He had seen only one case of Argyll Robertson pupil in encephalitis lethargica; nor had he observed nystagmus as a sequel. Blepharoclonus was a common accompaniment of the post-encephalitic stage of Parkinsonism.

Discussion.

Dr. J. R. PERDRAU spoke of the small proportion of cases of encephalitis lethargica in the epidemic of 1919–21 which were correctly diagnosed, judging by the material which had been sent to him for investigation. In many the condition had been found to be tuberculous meningitis, and in others syphilis. In some instances in which the picture presented by the cerebro-spinal fluid seemed to be consistent with encephalitis, it had turned out to be cerebral tumour or some such condition. The supposed relationship of the virus of herpes to encephalitis lethargica was very important. It had now been isolated in that disease about ten times. Flexner was the chief protagonist of those who said that the virus of herpes could not have anything to do with encephalitis lethargica. Dr. Perdrau dealt with his arguments in detail, expressing the view that none of them was sound enough to invalidate the conclusion which they attacked.

Mr. MONTAGUE HINE gave particulars of the case of a young man, aged 24, whom he had first seen three and a half years ago. Two months before that date he had contracted a sudden febrile illness, associated with a rise of temperature, giddiness, pains in the eyes, and headache. Influenza had been diagnosed. A week later, as a complaint was made that the eyes had gone wrong, the doctor had thought that it might be encephalitis. When the speaker saw the patient he had had hemianopia on the left side, complete in the lower quadrant, partial in the upper. There had been little change since, but memory was much weakened, though the man had resumed his work. No Parkinsonism had developed.

Dr. W. J. ADIE considered that the diagnosis of encephalitis lethargica was made far more often than was justified. If papillœdema was found in a doubtful case he regarded it as a point against the diagnosis of encephalitis. The symptoms which Mr. Williamson-Noble had mentioned in his paper did occur, but were not distinctive nor of diagnostic value. The Argyll Robertson pupil was very rare and by itself was much more likely to mean syphilis. But there was one sign in the eyes which was very important in the diagnosis of encephalitis—namely, the lack of convergence and absence of reaction when the eyes converged to look at a near object.

Dr. GORDON HOLMES expressed his agreement with Mr. Williamson-Noble. In the acute stage of encephalitis lethargica palsies might be very irregular, but in nearly all cases there was a predominance of disturbance in convergence, often associated with complete fixation of the pupil when attempting to converge for accommodation; accommodation also was mostly paralysed. It was important, from the point of view of diagnosis, to remember the rarity, in encephalitis lethargica, of isolated complete ocular palsies. He quoted a case in a girl who, in 1920, when there was much encephalitis in London, came with slight sixth nerve and partial third nerve palsy, and a dilated inactive pupil. Eight years later, however, she had been found to have none of the sequelæ of the disease, but a recurrence of the palsies, this time associated with a lesion of the ophthalmic division of the fi nerve. A common symptom at the present day v the reverse of the Argyll Robertson pupil, but he h seen the true Argyll Robertson pupil in people v were recovering from the disease. He agreed w those who said that most of the cases having pa œdema and congestion of the disc with swelling of veins proved not to be encephalitis. He had fou that if the patient suffering from oculo-gyric cr lay flat on the couch with the head hanging o the end the severity was greatly lessened; henc seemed likely to be a disturbance of the re mechanism.

Mr. M. S. MAYOU referred to two cases, man a wife, who had suffered from encephalitis lethar and in whom secondary optic atrophy had develo later. He believed optic neuritis had also b present.

Dr. WILFRED HARRIS said there had been a dist change in the type of the ocular palsies seen in rela to the various epidemics of encephalitis lethar prevalent in this country since 1918, when in numb of cases there had been a marked double third ne palsy. He had not seen that in association with acute stage of the disease for some years. He agr with Dr. Gordon Holmes that sometimes th patients showed a loss of the light reaction in pupil. It was not surprising it should be a seque the disease seeing that any partial lesion of the th nerve might be followed by the Argyll Robert pupil.

The CHAIRMAN said that in a disease wh presented so many phases it was of the utm importance to try to ascertain what manifestat could be regarded as diagnostically signific especially when the patient came in a chronic st One of the most important of these, in his experie was loss of the capacity to move the eyes upw Another sign which had been present in severa his cases of the disease was an oscillation of the balls. There was inability to move the eyes i particular direction—it might be to one side upwards—then the eyes oscillated in diffe directions for a second or two, and settled do It resembled the quivering movement seen a dislocation of the lens. It could not be calle nystagmus. It might be a very valuable sign in recognition of an early case of encephalitis lethar whose nature was otherwise obscure.

NORTH OF ENGLAND OBSTETRICAL AN GYNÆCOLOGICAL SOCIETY.

Exhibition of Cases and Specimens.

AT the annual meeting of this Society held Manchester on Jan. 27th Dr. H. LEITH MUR (Liverpool) was elected President for the ens year.

Dr. K. V. BAILEY showed a specimen of

Multiple Uterine Fibroids with Torsion of One Ped

The patient was aged 36 years. The menstrual his was normal. There was no menorrhagia or leucorrhœa, there was definite congestive dysmenorrhœa. The pa had been aware of a "lump" in the right iliac region du the last 12 months. This had occasioned no symptoms six months ago, when an attack of acute abdominal occurred at the close of a menstrual period. This pa off after a few hours, and there was no recurrence until a v before admission, when a similar attack occurred, bu greater intensity. During the few days prior to admis the patient had experienced some dysuria. There wer symptoms of pressure on the rectum. On examina a firm, hard, mobile mass, occupying the right iliac re could be palpated and its origin from the pelvis was t able. The cervix was smooth and conical, and the was connected and continuous with two irregularly rou hard, but mobile pelvic tumours, which appeared t situated in a position anterior to a somewhat bulky ut and roughly one on either side of it. A diagnosis of ovarian tumours, with torsion of the pedicle of one of t was made.

n opening the abdomen the uterus was found to be the of numerous fibroids. The two masses which had n palpated vaginally were two subperitoneal fibroids nging from the antero-lateral aspect of the uterus and sessing definite pedicles. Torsion of the pedicle of one hem had occurred. The uterus and its appendages were oved by subtotal hysterectomy.

he second subperitoneal fibroid, the size of a fœtal d, had undergone hyaline degeneration, and there was lence of calcification in its substance.

Dr. Bailey said that it was interesting to note the ence of menorrhagia, notwithstanding the numerous erstitial fibroids present. He had operated ently on three other cases of multiple uterine oids, in none of which had menorrhagia been a nptom.

Dr. J. W. BRIDE showed a specimen of fatty tumour the uterus.—The PRESIDENT said that, judging m the size of the fat globules seen in the micro-pical sections, it was clearly a case of fatty ltration.

Dr. S. B. HERD described a case of

Puerperal Ovarian Thrombophlebitis.

he patient was aged 30. Four previous confinements, normal except for œdema of legs during last three months he fourth pregnancy. During present pregnancy had ked œdema of ankles during the last two weeks. She delivered at home by fairly easy high forceps. She was nitted to hospital during the third day after delivery h a temperature of 100·4° F., pulse-rate 120. There was ht jaundice, she looked ill, and was anæmic. There was ema in both ankles. Lochia normal. Uterus tender well involuted and no swellings palpable. The urine tained no pus but there was a feeble growth of staphylo-ci. The temperature settled down next day, and the rus continued to involute. Blood culture negative. the eleventh day another rigor took place but there e still no localising symptoms. Patient was given serum quinine, ergot, and pituitrin. On the twelfth day there tenderness in the popliteal space and left calf, but no a was palpable. There was tenderness in the left fornix no swelling. The uterus was normal. On the following blood culture showed chained streptococci. On the rteenth day the abdomen was opened. The left ovarian a was found to be thrombosed, the thrombus extending ost, if not quite, up to the renal vein. Ligature and ision of the left ovarian vein was performed, and the ovary was removed. No other abnormality was found the abdomen. The patient was very shocked after the ration and died 15 hours later in spite of blood trans-ion. There were no further rigors.

The conclusions Dr. Herd drew from the case re (1) the importance of early diagnosis; (2) that nplete excision of the vein was preferable to ligature; d (3) laparotomy might be performed earlier in vious cases of pyæmia where the patient was idly becoming worse, in spite of active treatment.

Prof. MILES PHILLIPS (Sheffield) did not consider t laparotomy was justifiable in a serious case of erperal septicæmia, unless the diagnosis was tain.

Dr. K. V. BAILEY described a case of

Atresia of the Vaginal Vault causing Dystocia.

vaginal examination during labour no cervix external os could be felt. The vaginal vault was irely closed, and a band of scar tissue ran across middle of it. The vault bulged under tension either side, and there was considerable thickness tissue composing it. A healthy male child was livered by Cæsarean section and the uterus removed.

Mr. J. E. STACEY (Sheffield) described a similar se delivered by Cæsarean section.—Dr. F. H. CEY (Manchester) also described a similar case which rupture of the uterus occurred early in bour and hysterectomy was performed.—Prof. A. NALD (Manchester) attributed the presence of cessive scar tissue in the vagina following col-rrhaphy to the use of strong and harmful anti-otics. — Prof. FLETCHER SHAW (Manchester) ntioned recent cases of sloughing and stenosis the vagina following the use of methylated spirit as antiseptic.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held at the Miller General Hospital on Feb. 10th, Dr. CHARLES THOMSON occupied the chair and Dr. R. TRAVERS SMITH gave an address on the

Origin and Diagnosis of Functional Cardiac Murmurs.

He insisted that the subject was important in that it was not rare to meet patients who had been condemned to invalidism because such murmurs had been mistaken for signs of serious organic disease; because special books on heart affections rarely discussed the precise mechanism of these murmurs; and because books on general medicine, whilst giving some clinical description of these murmurs, usually did so only under the heading of anæmia. He pointed out how easily it can be proved that many patients with functional murmurs have no anæmia, and vice versa. The commonest functional murmur, the pulmonary systolic, was due to diminution of tonicity, with consequent dilatation and impaired contractility of the conus arteriosus, the thinnest and weakest part of the outer boundary walls of the ventricles. Thus, at its systole, the larger and stronger portion of the right ventricle forced blood through the dilated conus, through the relatively narrow pulmonary ring, and into the larger lumen of the pulmonary artery. He submitted that this condition was sufficient to cause a murmur, and that dilatation, distortion, or displacement of the pulmonary artery by the enlarged conus was not essential. It was difficult to understand how a dilated conus could pull up the apex, and, at the same time, push up the pulmonary artery. Having discussed the variations of pulmonary functional murmurs with exertion, excitement, posture, and pressure, Dr. Travers Smith stated that expiration constantly accentuated them, and inspiration diminished them, especially when forced. The murmur would sometimes become audible only during prolonged forcible expiration. He attributed this "respiratory rule" to the fact that inspiration widens the pulmonary capillaries, diminishing the pressure in the pulmonary artery, so that the dilated conus has less pressure to overcome, therefore its contraction more nearly approaches in completeness to that of the rest of the right ventricle. During expiration this sequence is reversed. Apical and tricuspid systolic functional murmurs were attributed primarily to diminished muscular tonicity at the left and right auriculo-ventricular orifices respectively. It was suggested that the three murmurs hitherto mentioned might well be called "hypotonic murmurs," in that tonicity was the myocardial function most impaired. The vast majority of these murmurs disappeared when the general body tone was attended to appropriately, and, therefore, these murmurs were never, in the absence of other signs of heart failure, sufficient evidence on which to base a diagnosis of any serious cardiological condition—though the cause of the general debility might be serious. What was sometimes called an aortic functional murmur was usually pulmonary, transmitted to the aortic area and occasionally along the carotids; it then followed the "respiratory rule" at both these situations. If a separate aortic murmur existed and was due to a corresponding local dilatation of the left ventricle to that of the conus on the right, such an aortic murmur ought to increase with inspiration, which raised aortic pressure. Lastly, bruit de diable, subclavian, cardio-respiratory, and pleuro-pericardial sounds were dealt with. Having pointed out that every abnormal sound hitherto mentioned was systolic in time, Dr. Travers Smith said that on a few very rare occasions he had heard transient diastolic murmurs that he considered functional because they had only been heard in cases with loud pulmonary functional murmurs. He attributed them to the diastole of the right ventricle sucking blood back from the dilated conus as well as from the right ventricle, and the meeting of the two streams. On each occasion these diastolic murmurs were heard over the conus and were traceable downwards.

CHARITY ORGANISATION SOCIETY.

A SPECIAL meeting of the Council of this Society was held at Denison House on Feb. 13th to discuss the relationship of the

VOLUNTARY HOSPITALS AND THE PUBLIC AUTHORITIES.

Lord DAWSON, who occupied the chair, announced that the object of the meeting was to discuss how the hospital accommodation of London could be best directed and coördinated. The progress of medical science, he said, and the alteration in the social needs of the people called for a larger supply of hospital accommodation than was formerly necessary. This demand had been met largely by voluntary effort, reinforced in recent days by the utilisation of some of the poor-law hospitals. This use of the poor-law hospitals for the treatment of the same classes as used the voluntary hospitals had been made possible by the separation of their function of the care of the aged and infirm from that of the treatment of persons suffering from illness or injury. These municipal hospitals—he used this term advisedly, as it should properly replace the old name "poor-law"—had been started on the rates, and had gradually attracted to their staffs consultants and specialists. It must be remembered that their work would grow. When the Poor-law Reform Bill became law, the public authority in London would be responsible for over 100,000 beds. Were there then to be, he asked, two parallel and competing hospital systems, or was there to emerge a well-thought out system of coöperation? The big teaching hospitals of London were part and parcel of the national life, and their traditions were centuries old; on them depended the future supply of doctors and nurses and, very largely, research into new means and methods, and to them the profession looked for guidance. No wise statesman, therefore, would try to undermine their position, but would ensure their utmost use in any national scheme. They had become what they were chiefly by the flexibility of their administration, which encouraged initiative, and which contained none of the cramping routine which seemed inseparable from State-aided institutions. They were, in short, the embodiment of

The Voluntary Spirit.

This was the management of hospitals by bodies which did not owe their origin to any State or municipal government, though this government might lay down certain general conditions. The voluntary hospitals were gathered under the ægis of the King Edward's Hospital Fund, which secured a certain amount of coördination without interfering with their independence. When the public authority took over its 100,000 beds, were they to utilise the great experience of the voluntary hospitals in building up their system, and preserve their spirit, or were all hospitals to fall under a bureaucratic control, with its rigid restraint and costly expenditure? To administer the great teaching hospitals of London would mean the addition of 8*d*. in the £ to the rates. If the voluntary system was to be maintained, the voluntary hospitals must rise to the opportunity. They could not stay where they were; they must either recede from the position they occupied or shoulder wider responsibilities, leading the new movement in friendly coöperation with other bodies.

Sir WILLIAM HAMER then read the paper printed on p. 334 of this issue of THE LANCET.

Dr. GRAHAM LITTLE advocated the retention of the voluntary system unmarred. Its characteristics—independence and charity—had attracted the best men and women to its service for generations past. With the consequent development of medicine had come an increased demand for treatment, which was focused upon the voluntary hospitals. The poor-law infirmaries which had grown up alongside them, tended by reason of their constitution to a certa lack of individuality; their organisation was ster typed and inelastic. Supported by the public pur they tended to compete with the voluntary hospit in equipment, but not in personnel. Although th was ample accommodation for the population, so hospitals were full to overflowing, and the state affairs called for a redistribution rather than provis of fresh beds, which was one of the most expens items in hospital administration. The provision apparatus and special services was another cos item, and if specialist staffs were paid for at mar rates the figure would again be very high. T voluntary hospitals of London needed 11,000 m beds; the infirmaries had 20,000 to 30,000 b empty, according to season. Several factors accoun for the anomaly—the atmosphere of an institut where personal service was given freely was entir different from that of an institution run by sala officers under a Government department, wh individuality was lost. Patients were attracted to independent and ambitious staffs of the hospit Poor-law suffered from easily removable handica for instance, legal disqualification of pauperi and the rule that only patients from the dist could enter an infirmary. The inherent disadvant was, however, the prohibitive cost of providing c patient departments and special medical and surg services, and the unlikelihood that the same class officers would be secured by payment as worked the voluntary institutions. Dr. Little proposed establishment of an advisory council, to be t first in the metropolis and then, if successful, in provinces. This body would contain delegates fr the King Edward's Fund, the Ministry of Hea and the London County Council, and should succ in coördinating the service if it remained essenti voluntary. This scheme worked well in cert universities which received large sums of public mo without losing their independence.

A Scheme for Coördinate Action.

Dr. HUMPHREY NOCKOLDS sketched the four m facts which rendered the question acute. First was difficulty the voluntary hospitals had in find money; second, the increasing population, especi in areas where large numbers of new houses were be built; third, the progress of medical science, wh entailed an ever-increasing expenditure on methods; and fourth, the increasing desire of public for satisfactory hospitals. Commenting on th in order, he remarked that a change had taken p in the quality of the funds. Very little was hear the voluntary subscriber; money was energetic collected from patients, and various means such "golden ballots" had been resorted to; one hosp in South London had drawn on the rates and oth were subsidised. It was admitted that volunt hospitals were unable to cope with the demands m on them. The remedies suggested were as follo (1) The State should take over all hospitals; would mean the destruction of the voluntary syst and would be the worst possible course. (2) The l authorities might make grants; these would hav be so large that no Government would ever sanc them unless popular representation were given; voluntary subscribers would then fade away and S control be established. (3) The voluntary hospi should be linked up with and control the poor- institutions, and find the money for both. The of organisation between hospitals and their slowne procedure annulled any claim they might have t the organising authority for a unified hospital serv (4) The last proposal, which the speaker believe be the only really practical one, was that the l authorities should institute new general hospit making the present poor-law hospitals the basi their scheme and retaining the voluntary hospit This would allow each hospital to administer it while relying on a broad, combining central autho to decide the general medical policy. The unit w be large—a county, possibly—with suitable sub

ns. The poor-law hospitals would be removed irely from the immediate sphere of poor-law ief. The danger of bureaucracy was real, but not urmountable. The general medical hospitals must left free from red tape, but their requirements were ite different from those of an institution for chronic es, and if the nucleus of their staffs were appointed m the voluntary hospitals the evil should be averted. e poor-law hospitals were not unworthy to take part an organisation on these lines; they had already umed a large part of the burden of the voluntary spitals, in spite of many handicaps like lack of atment facilities, the fear of the ratepayers, and e almost complete apathy on medical matters of the or-law section of the Ministry of Health. It was the shion to decry these institutions and say that patients uld not go into them; the fact was that they had to er for the patients refused by the voluntary spitals. Dr. Little's figures about empty beds did apply to London, and patients, so far from being uctant, often asked to be sent to the infirmary. It s true that the poor-law hospitals were inadequately ffed, but this fault, with others, was being removed. Lewisham and Eltham, with their huge new popula- ns, the guardians had stepped into the breach, ich would otherwise have remained empty, against ch opposition and with no help from higher horities. A new voluntary hospital was being cted at Shooter's Hill, and would run without any nexion with the new poor-law provision; this s almost a public scandal. The example was an reme one, but showed the present state of hospital anisation.

Discussion.

Miss E. FULFORD, chairman of the Fulham rdians, strongly defended the poor-law system m the criticisms made by Dr. Graham Little. ere were no empty beds in Fulham Hospital. e atmosphere of free service was equal to that of voluntary hospitals, the legal disqualification had n removed in 1918, and guardians put their ients' needs before those of the ratepayers. reover, the central authority and the Ministry of alth were most helpful.

Mr. B. METIVIER, of the Edmonton guardians, posed the fallacy that a consultant was con- minated by being paid for hospital service.

Lord RIDDELL wondered whether subscribers would ntinue to support the voluntary hospitals when they v public institutions doing just as good work and ng as well run. Public bodies, however, lacked the rit of research, and a teaching hospital could not ceed on the cast-iron lines of a rate-supported anisation. To preserve the voluntary system ant preserving the voluntary subscriber, and many sons were opposed nowadays to the principle of ving the voluntary hospitals supported by a limited ss and would prefer an increase of, say, a penny on rates.

Mr. E. A. H. JAY, the propaganda secretary of King ward's Fund, agreed that people would only scribe to a thing which could not otherwise be ained. Endowments, which up to 1914 had been gely adequate, had now dropped in value to per cent. of the required revenue; 32 per cent. was d by public authorities, and the remainder had to got from subscribers. Voluntary hospitals, if they e to continue to fulfil a function that no other anisation fulfilled, should devote themselves to ating cases requiring their unique special equipment, training doctors and nurses, and to research. yments from the County Council might be very ch larger in the future than they were at present.

The CHAIRMAN closed the proceedings with an portation to remember that the voluntary hospitals e a vital part of the credit of the nation abroad, mirror of the national life, the loss of which could possibly be contemplated.

Reviews and Notices of Books.

A TEXT-BOOK OF INFECTIOUS DISEASES.

Being the third edition of *Goodall and Washbourn's Manual of Infectious Diseases*. Revised and in large part rewritten by E. W. GOODALL, O.B.E., M.D., B.S. Lond., lately Medical Superintendent and Lecturer on Infectious Diseases and Fever Hospital Administration at the North-Western Hospital of the Metropolitan Asylums Board. London: H. K. Lewis and Co., Ltd. 1928. Pp. 718. 30*s*.

DURING the nineteen years which have elapsed since the second edition of this manual was published a vast amount of work has been accomplished, more especially in the fields of bacteriology and immunology. The third edition has increased in size by 300 pages and has developed from a manual to a text-book. Dr. Goodall's long and intimate acquaintance with all the infectious diseases met with in this country makes this volume very acceptable to all who make a special study of such diseases, and at the same time renders it a very useful reference book for students and practitioners. The introductory chapter is specially written for D.P.H. students who wish to know "something about epidemiology." The ordinary student can afford to leave this chapter until he knows something about the diseases themselves. The next five chapters deal with fever, contagion and infection, disinfection, rashes simulating those of the specific fevers, and sore-throat, and form a necessary introduction to a closer study of the actual fevers, which are fully discussed in the rest of the book. These early chapters are clearly written. Diphtheria, a disease which—in spite of serum treatment—is still serious, is dealt with very thoroughly in a chapter of 70 pages. Dr. Goodall considers that "the Schick test is of no value in the diagnosis of diphtheria," a statement which will not be readily accepted by those who have had opportunities of studying its significance in this connexion, and who will rather agree with Dr. Rundle in Ker's Manual of Fevers, who says that "100 per cent. of diphtheria cases are Schick-positive at the beginning of the attack." Dr. Goodall does not approve of swabbing contacts, but recommends Schick-testing and active immunisation as the solution of the problem of prevention. The author's experience of intubation in laryngeal diphtheria makes interesting reading; no mention is made, however, of feeding by the mouth in such cases.

The chapter on scarlet fever runs to 60 pages and includes an account of the Dick test, the Schultz-Charlton reaction, and immunisation against the disease with streptococcal toxin. Dr. Goodall thinks that the results of immunisation are so far not encouraging. Concentrated scarlet fever antitoxin is recommended by the author in the treatment of this disease in doses of 10–50 c.cm., given intravenously if necessary, but he remarks that "the serum appears to have no effect on complications when once they have set in." Most observers will agree with this.

The chapter on influenza is interesting, dealing, as it does, with the pandemic of 1918–19. Encephalitis lethargica, anterior poliomyelitis, and cerebro-spinal fever are all carefully considered. In Dr. Goodall's opinion the prognosis of encephalitis lethargica should be extremely guarded, and he quotes the epidemics in Sheffield and Belfast to prove this. For anterior poliomyelitis the Thomas straight frame with headpiece is recommended at first, and later natural movements of the affected limbs. Dr. Goodall does not apparently advise electrical treatment locally, and quotes Lovett, who says "that, after many years experience of it, he has never been able to satisfy himself that it was of any value." Many observers will agree with this. In the sequel there is a very clear and useful description of the cerebro-spinal fluid in all these diseases. Dr. Goodall considers that the temperature of the measles ward

should be 60° F., and that the patient should be protected from draughts with screens. This is scarcely necessary, and, as long as a measles patient is warm in bed, the freest possible ventilation is undoubtedly best, as recommended by Foord Caiger, and especially by Ker. Recent work on the prophylaxis of measles is discussed by the author in all its aspects. The chapters on small-pox, chicken-pox, typhus, and enteric fever are excellent and well worth reading from beginning to end. The chapters on glanders and anthrax are still retained. There are throughout excellent plates, photographs, diagrams, temperature charts, and tables which the student, in particular, will find extremely useful, while the appendices contain interesting matter. The reader will thank the author for dotting the book so plentifully with references.

Both author and publisher are to be congratulated on the third edition of this volume which is thoroughly up to date and should make a valuable addition to the library of every medical practitioner.

MALARIAL TREATMENT IN SYPHILIS.

Die Malariatherapie der Syphilis. By Dr. JOSEF MATUSCHKA and Dr. RUDOLF ROSNER. With an Introduction by Prof. ERNEST FINGER. Vienna: Julius Springer. 1927. Pp. 84. M.4.80.

THIS is the first account we have seen of the application of malarial treatment to syphilis in general. It records observations extending over four years and embracing 500 cases, in only 135 of which the nervous system was involved; and since the effects of malaria on the various forms of nervous syphilis are now widely known the main interest centres in the treatment of the other cases. The argument on which the authors base their wider application of malaria therapy is that as salvarsan and mercury are not direct spirochæticides their apparent action in the human body must depend on inducing a reaction of the human organism. It is this reaction and not the drugs themselves which destroy the infective agents; the action being apparently a mediate one, it seemed that the effect of any course of chemical treatment must depend on the state of the human body concerned and that various influences might increase or decrease the body's reaction.

Fever was already known as a powerful adjuvant, but experiment showed that alone it could not effect a cure, and might, in fact, hinder later treatment combined with intensive salvarsan courses it gave extremely good results. In early syphilis—that is, with infections of less than two years' standing—such combined treatment rendered the Wassermann reaction of the blood negative in 99 per cent. of cases and in all these cases the negative reaction was maintained; the cerebro-spinal fluid became negative in all cases in which before treatment it had been positive, but there were a few cases in which fluid previously negative to the Wassermann test became positive during the treatment. Serological relapses have hitherto been extremely rare, but clinical relapses, though still very few in number, have been a little more frequent. With infections of longer standing the results, while less brilliant, were yet better than those obtained by any other method of treatment, the Wassermann reaction of the blood becoming negative in 61 per cent. and that of the cerebro-spinal fluid in 55 per cent. of cases; no serological relapses have been observed in this group. In selected cases of pregnancy the treatment was well tolerated and gave excellent results. Congenital syphilis responded partially to the treatment, cases of early interstitial keratitis being aborted and those of the established condition being often greatly improved.

The authors of this brochure are convinced that in malaria therapy medicine has a powerful new weapon. Their technique, which is fully described, involves two inoculations of malaria, and they find that the incubation period is on the average five days. During the attack of malaria the Wassermann reaction, if not already positive, usually becomes so. The m important contra-indication to the treatment is card disease. Many individual cases are described various problems raised are discussed.

Altogether this is an interesting account o valuable piece of pioneering work.

Reports and Analytical Record

AUSTRALIAN WINES:
(1) MELVINA WHITE; (2) IMPERIUM RE
(SOUTHARD AND CO., LTD., 2, ST. DUNSTAN'S HILL, E.C

(1) Melvina White (Australian), when analysed, found to have the composition :—

Alcohol by volume	19·4 per c
,, weight (grammes per 100 c.cm.)	15·3 ,,
Total sugar	9·55 ,,
Sugar-free extractives—	
Total acid as tartaric	0·27 ,,
Mineral matter	0·31 ,,
Water	74·57 ,,

Preservatives were tested for with negative resu The wine is of a rich type and possesses an agree palate and aroma. These qualities in conjunct with its purity add to its value as a wine for t purposes.

(2) On analysis Imperium Red (Australian) g the following results :—

Alcohol by volume	19·3 per ce
,, weight (grammes per 100 c.cm.)	15·2 ,,
Total sugar	9·9 ,,
Sugar-free extractives—	
Total acid as tartaric	0·37 ,,
Mineral matter	0·38 ,,
Water	74·15 ,,

Preservatives, and colouring matter not natural a red wine, were tested for with negative results. mineral matter contains iron to the extent of 2·6 p per million of wine. The wine has a rich sweet fr flavour, and resembles a good port in appeara aroma, and palate. It is a pure and sound wine, the presence of organically combined iron may regarded as an asset. So high grade an Austra product merits the attention of medical men and ot who have to advise on matters of food and bevera

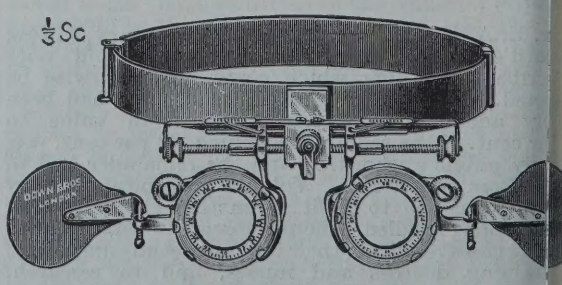
A NEW FORM OF TRIAL FRAME.

IN estimating by retinoscopy the refraction o school-children the combination of the ordinary t frame and head band here illustrated has been fo



convenient. It can be readily fitted to the vary sizes and shapes of the head and once fitted rem firmly in position. I have given it a year's trial can confidently recommend its use.

The apparatus has been made for me by Mes Down Bros.

Reading. JOHN PARRY PRICE, M.D. Ox

THE LANCET.

LONDON: SATURDAY, FEBRUARY 18, 1928.

THE BICENTENARY OF JOHN HUNTER.

JOHN HUNTER is one of the great men whose fame as not only withstood the test of time, but has ncreased steadily as the developments of physiology and he progress of surgery have proved his work prophetic nd fruitful beyond anticipation. Sir HOLBURT VARING, in the Hunterian Oration delivered before ie Royal College of Surgeons of England on Tuesday st, reviews briefly the progress of surgery during the st 160 years, taking 1768 as approximately the date hen HUNTER'S boundless imagination and inventive- ess, spurred on by an insatiable curiosity, began to ave the practical shape which led to the revolution of ir science. "HUNTER fully recognised," said the unterian Orator, "that a minute and thoroughly omprehensive knowledge of the pathological processes curring in inflammation and growth is the real asis of a considerable amount of practical surgery." his may seem to be a colourless way of describing UNTER'S essential message to us, but it is an exact ay, and none the less forcible because it is short and adorned. The conception thus briefly outlined as absolutely new to HUNTER'S generation; its plications were not perceived until HUNTER'S aching was the scientific creed of all surgery; and s developments, which became immense with the portunities afforded by LISTER'S discoveries, are ill unrolling themselves before us.

In the Vicary Lecture Dr. G. C. PEACHEY, while entifying the homes of WILLIAM and JOHN HUNTER London, has added much interesting and agreeable mment, helping us to visualise the intensive industry the famous brothers. We learn once again how uch the immortal work of the younger owed in its ception to the brains of the elder, as well as to his irit of sacrifice; and we get a good idea of the vironment of the scientific student in the eighteenth ntury. WILLIAM HUNTER derived almost nothing om academic instruction, and JOHN was practically lf-taught, save where he obtained information rough contact with his brother, from a few colleagues, d doubtless through his labours in instructing pupils. ience in those days had no endowments at all in gland, and the benefits which JOHN HUNTER nferred upon mankind were created by his own ellect, working in a world where nothing but search counted for him. Nor were any easy aids to cial advancement given in the reigns of the Georges to entific workers, as they were bestowed freely upon litical partizans; the modesty of the social circle which JOHN HUNTER moved while he was pouring t treasures of brain—and all the money he could rn—in behalf of his fellows, is indicated clearly in e Vicary Lecture, and emphasised in a series of ters to his parents from Prof. WILLIAM HAMILTON, e pupil of both brothers. These we have been able reproduce through the kindness of his descendant, . LOUISA HAMILTON, and they form a remarkable dition to our knowledge of the workaday life of the dical student a century and a half ago. The series ses with one from a London physician to Prof. LLIAM HAMILTON'S father, THOMAS, who was ling the chair in anatomy at the University of Glasgow, to which the son succeeded. In this a vivid picture is given of the great master actually at work, a pathetic picture when we recall his physical frailty at the time; and how real that frailty was we can gather from Dr. J. A. RYLE'S communication on another page. Dr. IRVINE'S letter displays JOHN HUNTER immersed in his marvellous investigations, and it is timely, indeed, that the document should attain publicity on his two-hundreth birthday.

IODINE IN THE PROPHYLAXIS OF GOITRE.

INVESTIGATION into the causation of endemic goitre, still so prevalent in many parts of the world, was quickened by interchange of view at the recent International Goitre Conference held at Berne, and reported [1] for us by Prof. F. DE QUERVAIN, himself one of the foremost authorities on the subject. Clinical and museum specimens in abundance illustrated the vital importance of goitre in Switzerland. The Congress being preliminary, its time was largely occupied with the ætiology and epidemiology of endemic goitre, the most generally accepted view being that there is some toxic cause, its nature still unknown, the action of which can be prevented or counteracted by the ingestion of iodine, and that endemic goitre arises when there is a deficiency, absolute or relative, of iodine in the food and drink. The three introducers of the discussion—WAGNER JAUREGG (Vienna), MUGGIA (Sondrio), and SILBERSCHMIDT (Zurich)—as the result of experience in different districts, advocated the general preventive treatment of goitre by the use of iodised salt in the proportion of 5 mg. KI to each kilo of salt, the equivalent of gr. 1/26 to 1 lb. In the case of three varieties of iodised salt on sale in this country the strength varies from gr. 1/8–1/50 of NaI to 1 lb. of salt. Assuming that an average adult consumes about grs. 75 of table salt a day or 4 lb. in a year, it follows that if even the strongest of these salts is employed only gr. 1/2 of NaI would be consumed in 12 months. Such small amounts may be regarded as harmless; it is questionable if they are large enough to be efficient. In Austria, however, the use of iodised salt in the strength named above for three and a half years has been attended with a distinct diminution in the frequency of goitre during the school years. However this may be, it was agreed in general at the Berne Conference that in districts where goitre is endemic three measures are desirable: (1) the general use of a slightly iodised salt by the whole population in order to supply the physiological dose of iodine lacking in the food and drink; (2) goitres, when detected in the course of school inspections, require treatment with iodine under medical supervision; (3) care should be exercised to prevent the use of excessive doses of iodine in the treatment of adults. Swiss records have provided Dr. PERCY STOCKS, of the Galton Laboratory, with material for a valuable statistical survey[2] of the influence of iodine on the incidence of goitre and on the physical growth of school-girls. The worth of some previous surveys has been diminished, owing to difference of view as to what constitutes a goitre, but in this case the classification was that of the Swiss Goitre Commission, and the examinations were made almost entirely by the same medical officer. The routine treatment was to give one tablet a week of NaI 2 mg. (gr. 1/32), and the analysis clearly showed the efficiency of the treatment in reducing the size and incidence of the

[1] THE LANCET, 1927, ii., 1239.
[2] Annals of Eugenics, October, 1927.

goitres. Its effect was also observed on the growth of the girls between ages 11 and 16 who had goitre at the commencement of treatment. Information on this point was desirable, as it has been recognised by Swiss clinicians that in cases of endemic goitre there is a definite retardation of growth. Dr. STOCKS's analysis demonstrates an increase both in height and weight as a result of the iodine treatment, the more marked the goitre at the commencement of treatment the greater the increase in weight. It does not follow that iodine has a similar effect on the growth of normal girls in a non-goitrous district.

The prevalence of thyroid enlargement in English-speaking countries is still largely a matter of conjecture, although some exact surveys have been made. Dr. R. OLESEN based an estimate[3] of the frequency of goitre in Oregon and other North American States on the draft examinations of recruits. He has now gone on to the systematic examination of school-children. The observations,[4] which were all made by the same person so as to ensure uniformity, comprised the children in the schools of 32 towns in Oregon; 8181 boys were examined, of whom 1826, or 22·3 per cent., showed thyroid enlargement, while 3617, or 38·3 per cent., of 9427 girls were similarly affected. In Oregon, although there is less goitre in the sea-coast towns than in those situated further inland, thyroid enlargement is nevertheless fairly frequent near the sea. This distribution differs from that found in Massachusetts, where goitre is infrequent at Cape Cod and in the eastern part of the State near the sea, but is common in the western inland part. Examination of some of the water-supplies in Oregon shows a marked paucity of iodine; thus in the water supplied to Oregon City, in which the greatest frequency of endemic goitre among girls was found, only 0·06 parts of iodine per billion of water were found as compared with 2·50 parts in the water of New York City, and 105·80 in that of Stamford, California. There is no evidence to show that goitre in Oregon is in any way associated with pollution of the drinking-water, and the experience in that State indicates that a diminution of endemic goitre has followed the use of iodised table salt.

A survey of English school-boys and girls about the the age of 12, with the intention of ascertaining the frequency of enlargement of the thyroid gland in 1924, has also been made by Dr. STOCKS,[5] based upon results obtained by school medical officers for the Board of Education. Due allowance has here been made for the personal factor of the examiner, as some 600 medical officers were engaged in examining 375,022 children, their reference being to ascertain the number "in whom the thyroid is sufficiently enlarged for the increase in the size of the neck to be noticed on casual inspection without measurement or palpation." In order to secure uniformity in such surveys in the future Dr. STOCKS proposes that "enlargement of the gland shall be deemed to commence at a thyroid breadth of 42 mm. in boys and girls at ages 11–13," and as the normal gland increases very little between the age of 10 and 14, this standard may be applied to all children between their tenth and fourteenth birthdays. By the use of a simple gauge all thyroids below 42 mm. in breadth may be classed as normal, those above 42 mm. but below 55 mm. as moderately, and all above 55 mm. as markedly enlarged. As a result of this and other observations, the cautious opinion is expressed that "it would seem that prophylactic administration of iodine to girls in some endemic areas of England and Wales might be desirable." In a further paper by Dr. STOCKS, in association with Miss M. N. KARN a positive relation is found between thyroid enlargement in children and the mortality from Graves's disease in the large towns of England and Wales which leads them to infer that the factor which produces goitre is also one of the factors concerned in the causation of Graves's disease.

MEDICAL USES OF CARBON DIOXIDE.

THE many ways in which carbon dioxide is useful in medicine are now being belatedly discovered, but their application in practice lags behind and it may be worth while to review the facts as we know them. Its uses depend upon its action as a natural stimulant of the respiratory centre and first and foremost this action can be utilised with profit in administering anæsthetics. During induction many patients struggle and hold their breath, and it is found that by adding a small quantity of CO_2 to the inspired air, or by making the patient rebreathe what has been expired, the tension of the gas in the alveoli and blood can be so raised that long strong breaths are inevitable. Anæsthesia may thus be induced more rapidly if this is thought desirable. When the patient is unconscious respiration sometimes fails because abnormally deep breathing has reduced the tension of CO_2 in the blood, such failure occurring especially in connexion with intratracheal insufflation of ether and with gas-and-oxygen. Here again CO_2 offers a simple remedy, for it enables the anæsthetist to control the depth of respiration in accordance with the patient's changing state. Lastly, forced respiration of dilute CO_2 may be employed—provided that no objection arises because of wound or bandages—to wash the remains of the anæsthetic out of the system when the operation is over and bring the patient back to consciousness more rapidly.

All these seem to be legitimate uses of the gas, but they must not be adopted incautiously or without reference to the particular circumstances of each case. The claims put forward have perhaps been rather enthusiastic, and this leads Dr. R. M. WATERS, in a recent paper [7] based on six months' trial, to lay stress on the possible dangers of giving CO_2 to sick patients whose degree of acidosis is unknown. Quantities greater than those involved in graduated rebreathing should not, he says, be given to a patient unless the acid-base balance has been shown to be normal before anæsthesia was induced, and in support of this view he mentions that collapse and convulsions have occasionally followed its administration. Inhalations of CO_2 in concentrations of 15 per cent. or more cause a considerable rise of blood pressure and an increase of the coagulability of the blood, and Dr. WATERS considers that to change the amount inspired by sick people is to interfere with "fundamental physiology" and should not be lightly undertaken. His criticism, however, seems to be directed for the most part against the use of CO_2 in strong mixture. In a summary written from the more favourable point of view Dr. J. C. WHITE and Dr. L. M. HURXTHAL refer chiefly to dilutions of 5 per cent., and in this concentration regard it as valuable in many conditions in which the CO_2 tension in the alveolar air differs widely from the normal. In morphia or veronal poisoning, for example,

[6] Annals of Eugenics, October, 1927.
[7] Canad. Med. Assoc. Jour., 1927, xvii., 1510.
[8] Boston Med. and Surg. Jour., 1927, cxcvii., 1117.

he respiratory centre has become sluggish and needs rther stimulation although the tension is high; hilst in carbon monoxide poisoning the tension is w and 5 per cent. CO_2 is given to stimulate the ntre and promote greater oxygenation of the blood. fter respiration has been re-established by artificial eans this mixture should be given for 30 to 40 inutes, oxygen being used as a diluent because rboxyhæmoglobin dissociates more readily if the artial pressure of oxygen is raised.

In normal people inhalation of the gas is said to use no disagreeable sensation beyond a slight feeling f fullness in the head; the blood pressure and pulse-te are slightly raised. In cardio-renal disease with cidosis, however, the respiratory response to CO_2 is nsiderably increased and may be doubled, so that he greatest caution is required. In emphysema, on he other hand, there is little response even to air ntaining 11 per cent. of the gas. There seems to be misconception abroad that the cyanosis even of æsthesia, brain trauma, or morphia poisoning is ue to an increase of CO_2 in the blood. This is not so. ack of oxygen is the cause, and this can often be lieved by the hyperpnœa which small quantities CO_2 in the inspired air produce. The use the gas for eliminating poisonous substances n be extended to alcoholic intoxication—for alcohol, e ether, is eliminated by the lungs—and rapid covery from deep coma, with lessened after-effects, s been reported, though it should be noted that ildly intoxicated patients do not benefit to a propor-nate degree. In hiccup, which may be due to an normal stimulus reaching the respiratory centre a the phrenic nerve, CO_2 can be utilised to produce stronger and regular stimulus to displace the weaker e that causes the spasm.[9] Carbon dioxide may also employed (5 per cent. dilution in oxygen) to revive wly born infants; whilst depression of the respira-ry centre after cerebral operations, Cheyne-Stokes eathing, diminished coagulability of the blood, and llapse of the lung following thoracotomy are other nditions in which it has been of value. Whatever e object of its administration, caution is desirable to event the gas being given in cases of acidosis where e blood already contains an excess of it. Otherwise, wever, its use in low dilutions and with care seems be without danger, and may sometimes prove to be the greatest possible assistance.

RETIREMENT OF SIR FREDERICK WILLIS.

ON the last day of next month Sir Frederick Willis ll cease to preside over the Board of Lunacy Control, s place being taken by Mr. L. G. Brock, who has been pointed a Commissioner of the Board for this pur-se. Sir Frederick Willis succeeded Sir William rne as chairman seven years ago, after having been e of the principal assistant secretaries in the inistry of Health practically from its formation, and the permanent staff of the Local Government ard since 1890. He has, in fact, 42 years of public rvice behind him. His period of office at the Board Control has covered a time of great changes and fficulties, and the Board owes much to his wise idance. He was able in a high degree to hold the lance fair between the liberty of the subject and e need for efficient medical treatment and control, d his work was made the easier by the fact that was a grateful personality both to the local authori-s and to his medical colleagues on the Board. It y also be recalled that during the war he was in arge of the arrangements for the reception and re of Belgian refugees, and was honoured by the ng of the Belgians for this service.

Annotations.

"Ne quid nimis."

PERIODICAL MEDICAL EXAMINATION.

THE value of regular medical examinations of the healthy has been urged with much eloquence recently on both sides of the Atlantic, and it has become a serious question for medical men and insurance officers whether or not the adoption of periodical examination in this country should receive their support. Dr. H. G. Turney, in his presidential address delivered at the Assurance Medical Society on Feb. 1st, took a definite stand against the proposal, on the ground that the question was tending to become the infiltrating edge of propaganda for impressing on the popular mind the urgent necessity for watchfulness on the part of any individual who hopes to retain his health. Dr. Turney felt that there was a real danger that these vociferous warnings might help to establish something approaching a system of terrorism among the weaker-kneed section of the community. While expressing the conviction that the scheme in the States is in the hands of capable and honourable men, he doubted whether its introduction into this country would be attended by the success which it had met in America. We have not over here the large Babbitt class who have made a fortune in strenuous business, and have retired while still in the prime of life. They have unlimited leisure with little outside interest, and the advertisement columns of the newspapers give evidence of a stupendous demand for every kind of solace for bodily trouble which results from their tedium vitæ. One might be tempted to infer that the majority of American people live on a combination of patent medicine and semi-digested foods, and it is evident that a scheme of periodical stock-taking at the expense of the insurance company would be extra-ordinarily attractive. The investigation made by the Metropolitan Company of New York into the working of the system showed that hygienic sins were being committed by 99 per cent. of those examined. "One in three," said Dr. Turney, "ate too much meat, another third took too little water, a still larger pro-portion too much tea and coffee, and, horrible to relate, nearly half the whole number committed other import-ant but unspecified errors in diet. . . .From a study of the literature one might almost be led to infer that a rigid observance of all these hygienic prescriptions would ensure complete immunity from all bodily ailments except those of old age, and even as regards these, that they would be deferred to such a remote epoch of time as to be hardly worth considering." Unfortunately every doctor knows that the people who enjoy the best health are often those who take no heed of what they eat or drink, and who make a practice of defying the laws of health; and we have, as Dr. Turney pointed out, reluctantly to admit that there are as many different standards of health which are beyond our control, as there are of intellect and morals. Some people seem to have poor health from birth or adolescence for no reason, and have to live on the dole of hope offered by some enthusiast who promises that if they will take brown bread or give up butter, all will be well. Unfortunately the effect soon wears off, and the sufferer starts on a new voyage of discovery for a cure-all. The singular thing is that this congenital incapacity to make that smooth adaptation to environment which constitutes health, has very little influence upon the expectation of life, or upon the incursion of organic disease. The introduc-tion of a free system of examination would pander to those morbid cravings, and so far from improving health would, in Dr. Turney's opinion, concentrate people's thoughts on their internal processes and tend to perpetuate what is morbid.

The second fallacy exposed by Dr. Turney is that a slight bodily disturbance, to which the best of us is subject from time to time, will, if neglected, lead to serious disease. Doctors are constantly being exhorted

to seek disease in its small beginnings, but while it is true that the great diseases must have their beginnings, it is also true that the world is full of human beings who do not feel absolutely well all the time, and who outnumber those who are incubating organic disease by a hundred to one. Every sensible man knows that nothing perpetuates these troubles more than constant inquiries and sympathy, for they are in the main of psychical origin. The worst thing a doctor can do for a patient is to suggest, either by word of mouth or by meticulous examination, that these things generally lead to serious diseases, or indeed to any recognisable diseases at all. It is not well that a man should look too closely into his plate, and the less he thinks about it the better he is likely to digest what food he eats. Dr. Turney would hold that within very wide limits it does not matter a bit what a man eats, provided he does not eat too much.

Dr. Turney illustrates his thesis by the quiet revolution which has been in progress in the incidence of dysmenorrhœa which is dropping to vanishing point. It has been found that this trouble prevails in direct proportion to the notice taken of it and to the multiplicity of precautions taken against it. This, he feels, carries a lesson of the importance of healthy thinking for healthy living, and by healthy thinking he does not mean thinking about health, but rather the reverse.

PROGNOSIS OF TUBERCULOUS PERITONITIS IN CHILDREN.

OPINION is still divided on the prognosis in tuberculous peritonitis, a subject which Dr. P. Nobécourt and Dr. Ilitch Dragolioub discuss in the *Revue de la Tuberculose* for last December. Physicians of a former generation, basing their opinion on a study of the caseous forms of the disease, considered that the outlook was usually unfavourable. Their successors, recognising the tuberculous nature of what had been known as essential ascites, took a less gloomy view, whilst more recently Armand-Delille has claimed 100 per cent. of cures in a series of selected cases treated by heliotherapy. In this country a general impression prevails that the prognosis in the caseous form is grave, whilst recovery may be expected in the ascitic type. Accurate statistics, however, are difficult to obtain. The child of poverty who is poorly nourished, and who complains of vague abdominal symptoms, usually finds his way sooner or later to the dispensary, where the tuberculosis officer observes the pale face, thin frame, and flaccid abdomen. The condition may be due to tuberculosis, but is more probably due to faulty diet and unsatisfactory home conditions. A diagnosis alone stands between the child and recovery. If the child is pronounced to be tuberculous the whole machinery of the public health department is set in motion on his behalf. The diagnosis is accordingly made, and wisdom is justified of her children; but the cause of scientific accuracy is not so well served.

During the six-year period, 1921–26, 25 children suffering from tuberculous peritonitis were cared for by the Children's Medical Clinic at Paris. No case in which the diagnosis was doubtful was included in the series and an attempt has been made to ascertain the after-history of each child. The result may be summarised as follows:—

1. Died in hospital, or shortly after discharge		7 (=28%)
2. After-history unknown:—		
Disease worse at time of discharge	1	7 (=28%)
Disease stationary at time of discharge	2	
Disease showing signs of improvement at time of discharge	4	
3. Patients whose after-history was ascertained:—		
Dead	1	11 (=44%)
Disease persisting	5	
Clinical recovery	5	

The cases thus show a mortality-rate of 32 per cent., but this is a minimal estimate, for it is improbable that all the untraced patients survived, whilst of the survivors several still showed signs of active disease at the end of the period under review. Five of the children, it is stated, were suffering from the caseous form and all of these died. Ascites was a prominent symptom in 14 cases, among which were five recoveries and one death, two patients being seriously ill, and three improving at the time the paper was written. This evidence suggests that peritonitis is not, as some have assumed, a relatively benign form of tuberculous infection. Its immediate results may be grave, and the possibility of relapse or obstruction due to adhesions make the future uncertain.

A brief account is given of the methods of treatment employed. During the feverish phase, often associated with the onset of symptoms, Dr. Nobécourt and Dr. Dragolioub recommend rest, the local application of hot or cold compresses, and painting the abdomen with glycerine, iodine, and guaiacol. When pyrexia has subsided heliotherapy, open-air treatment, and exposure to ultra-violet rays is advocated. Calcium phosphate or carbonate and tincture of iodine may be given internally. Under this treatment in favourable cases pyrexia declines, ascitic fluid and tumours are absorbed, while return of strength, improvement in appetite, and gain in weight herald the return of health.

TEACHING OF ANATOMY.

IMPORTANT changes are gradually being introduced in many medical schools in the teaching of anatomy, and an interesting discussion of this subject took place recently at the meeting of the Association of American Colleges.[1] In an account by Prof. J. C. Grant of the methods employed at the University of Manitoba emphasis is placed on the value of displaying persistently to the student the general principles which govern structure. As Prof. Grant rightly maintains, the necessary details can only be remembered when they are fully understood: for this purpose it is clear that the teacher must appeal constantly to function, phylogeny, embryology, and clinical experience to explain various morphological points. If the curriculum permits of a reasonable time being devoted to this mode of anatomical study, which demands systematic supervision and guidance of the student in his practical work rather than extensive lecture courses, he learns to correlate structure and function, and gains anatomical knowledge by personal observation and reasoning. The student is ultimately in a position to generalise from his own observations and to understand the meaning and significance of structure. This is a far more useful, inspiring, and stimulating education than the old interest-killing method of memorising innumerable facts with little or no reference to the factors influencing structure. In a second paper,[2] Prof. E. J. Carey makes a strong plea for the teaching of living anatomy, and shows how the medical student requires information about the form of the living, and not the morphology of the dead, which is practically the only knowledge presented by pure descriptive anatomy. To procure this, dissection, which is undoubtedly still a necessity, must be supplemented by every available method which will reveal the conditions during life, and the modifications in form which result from functional processes. From the responses to a questionaire sent out by Prof. Carey to the leading medical schools in Europe and America, it was found that as yet in only about 50 per cent. was there any serious attempt to study anatomy in the living subject, or to employ such means as the X ray and fluroscope screen to correct the erroneous impressions created by studies of the cadaver. British readers may be relieved to learn that the replies to the questionaire showed that British-trained anatomists, more than those of other countries, do appear to emphasise the anatomy of the living. There has been an appreciable forward movement in this country in recent years, and probably none of our anatomy departments now fails to make good use of the living model. Nevertheless, too few have yet employed other means which are available to make anatomy live, and to demonstrate

[1] Bulletin of the Association of American Medical Colleges, 1928, iii., 1.

[2] Ibid., 1928, iii., 10.

at form and function are most intimately related d cannot be divorced. The tradition of descriptive atomy remains as a considerable influence, and ere is to-day an urgent need to return to the spirit Hunter and Harvey. Anatomy has a history to be oud of, and the future is full of promise; as Prof. liot Smith stated in a recent Thomas Vicary lecture "the possibilities for great achievements in anatomy ere never so great as they are to-day; and the ed for men who will devote their whole time and ergies to the exploitation of these rich veins of e was never so urgent as it is now in England." any of the newer methods at our disposal for the aching of anatomy and morphological research quire special equipment, but the cost is not prohibitive. What is needed most seriously is an increasing mber of trained men with the wider vision, better d more efficient coöperation between the anatomist, ysiologist, and clinician, and a reasonable time in the edical curriculum for the study of the fundamental bjects.

ALIGNANT INTRACRANIAL ENDOTHELIOMATA.

STUDY of the gross and microscopical anatomy in cases of intracranial endotheliomata at the eurological Section of the Mayo Clinic has revealed e existence of a definite small group differing from e usual picture of benign encapsulated tumours. r. Winchell McK. Craig, of the Mayo Clinic, who ports in full on 11 illustrative cases, remarks [1] that ey all showed cellular activity with areas of mbryonic undifferentiated cells and mitotic figures. rresponding to the pathological picture was a inical history of a rapid increase in the severity of e symptoms. A review of Dr. Craig's cases indicates at in five instances the onset of symptoms occurred ss than six months before the tumour became ident, and the degree of cellular activity was found be correspondingly pronounced. In the other six ses there was a history of symptoms for from one three years, but on closer examination it was found at the severity of the symptoms had increased ortly before the patients' admission to the clinic. roders has shown that endotheliomata of low alignancy present a greater degree of differentiation d tend to form whorl-like masses of keratinised ithelium, whereas the more malignant types of the eoplasm do not tend to develop such whorls, the lls being undifferentiated and mitotic figures being attered throughout. From the surgical standpoint hese malignant tumours, if they have not invaded the rrounding structures, are comparable to malignant mours elsewhere, and if they are completely removed definite cure is effected. If, however, they have oken through their capsule and invaded the surounding tissues recurrence is likely.

THE OPTIMUM DIET IN DIABETES.

THE employment of insulin in the treatment of iabetes has led to remarkable changes in the diets ecommended for cases of the severer type. That areful dieting remains necessary in all cases is, of ourse, a platitude, but insulin can be used to secure he metabolism of extra food to such a degree that he total diet selected is to some extent merely ependent on how high a dose of insulin a physician ares to employ. We have been told that in some ountries it is the custom for wealthy diabetics of he less abstemious type to indulge in periodic anquets at which they endeavour to remedy their xcesses by extra large doses of insulin. As the esult of this possibility of employing insulin to ounteract the effects of food, two schools of thought ave become more or less established. The first ssumes that the optimum diet in diabetes is the west which will sustain the patient's weight and rength, with the blood-sugar always within normal mits and the minimum dose of insulin sufficient to chieve these conditions. The other school starts by working out what is considered to be a good generous diet, often chosen on the basis of 3000 calories for a man and 2500 for a woman, and proceeds to give insulin in doses large enough to keep the patient sugar-free under such conditions. The second of these alternatives is probably more popular with the patient, although it usually involves more care on the part of his medical attendant if hyperglycæmia is to be avoided. But a much more important consideration arises when it is asked which of the two methods is likely to be of greater permanent benefit. An endeavour to answer this question is found in the paper by J. M. Rabinowitch in the current number of the *Quarterly Journal of Medicine*.[1] Working in the department of metabolism of the Montreal General Hospital this observer has made close statistical inquiry into the histories before, during, and after treatment of cases selected from about 1200 attending the clinic. Many variables naturally arise in such an investigation; not only will the quality and quantity of the selected diet influence a case, but factors such as exercise, increased metabolism accompanying acidosis, the dosage of insulin, and the acuteness of the cases, have all carefully to be considered. Without entering into complicated details of the author's paper, it is worthy of record that the main conclusion arrived at is to the effect that if treatment is designed to promote continued good health for the maximum span of life in any patient, the diet chosen should not only be low in carbohydrates but in its total caloric content, whether the individual patient does or does not require insulin. The inquiries of Dr. Rabinowitch point strongly to the importance of encouraging abstemiousness amongst diabetics.

THE TREATMENT OF MAL-OCCLUDED TEETH.

OUR knowledge of the ætiology of mal-occlusion is very slight, and despite the extensive literature devoted to orthodontics, little has been said on the practical management of cases as they occur to dentists in private practice. Mr. A. T. Pitts, in the annual report of the Dental Hospital of London, 1926, deals with this gap in the dental student's education. He points out that many factors, which have no place in text-books, play their part in determining success or failure of treatment. The three criteria which he considers to justify orthodontic intervention are serious æsthetic defect, interference with the normal function of mastication, speech or respiration, and any inevitable predisposition to dental disease in later life. He maintains that the dentist should strongly urge treatment if the two last criteria exist, but must remember that a slight irregularity may actually be pleasing rather than the reverse, and that parents who press for treatment of very slight displacement in their children's teeth should be discouraged, unless the defect is likely to increase. An appliance should never be looked on as anything but a necessary evil. An important part of the treatment is the recognition of the various types of irregularity and their causes. Mr. Pitts follows Angle's classification as a useful one, but he points out that it must not be regarded as an index to treatment. In cases of inferior retrusion, in his opinion, the deciding factor is the appearance of the chin. If the chin recedes, then an attempt should be made to advance the mandible; if the chin is well-formed, then the maxilla only should be treated. He strongly contests the view that treatment should be postponed until the early 'teens, pointing out that it is now recognised that the orthodontist should attempt to stimulate bone growth at its most active period, and not confine himself to forcing teeth into new positions when bone growth is finished. He finds that children of 6 or 7 wear appliances without any fuss or interference with temper or well-being. At that age the deciduous molars are firmly implanted, and little absorption of the root has occurred, but if the dentist waits until the child is 10, expansion

[1] Surgery, Gynecology, and Obstetrics, December, 1927.

[1] Quart. Jour. Med., 1928, xxi., 211.

in the molar region will not be very successful, and it may even be necessary to wait until the pre-molars erupt. There is also a distinct advantage in expanding before the permanent laterals appear. Later treatment may well be successful, but it will have to be more elaborate and more prolonged. Although the majority of children do not resent orthodontic appliances, profound psychological difficulties may be provided by the parents. Mr. Pitts tells amusing tales of parents who interfered, more or less successfully, with treatment which was causing their child no trouble whatever. He recommends the dentist to take the parents into his confidence, to explain to them as fully as possible the why and the wherefore of the treatment in its various stages. Dealing with the vexed question of fixed or removable applances, he holds that the wise dentist will use either according to the particular case. On the difficult problem of anchorage, he says that it is wise in every case to over-estimate the resistance of the teeth to be removed, and to under-estimate the resistance of the teeth to be used for anchorage; it is far better to have an excessive anchorage than too little. Although it may be necessary to raise the bite deliberately as part of the treatment, this should be looked upon as an evil procedure likely to do harm in ordinary cases. Irretrievable damage has been done by capping a bite when this was not necessary, and Mr. Pitts's advice to those who meditate this orthodontic crime is "don't." He is a whole-hearted advocate of extraction, but with certain qualifications. He thinks that extraction should be regarded as an ancillary method of treatment, and usually combined with an appliance. A patient from whom a tooth has been extracted should always be watched carefully to be sure that the gap is properly filled in. Practical advice like this is invaluable to the dentist and of great importance to the medical man. If the family doctor does not hold sound views the dentist may not see the case until too late or may plead the necessity for treatment in vain. The general practitioner of both professions would profit by a study of Mr. Pitts's paper.

THE HEALTH OF THE ARMY IN 1926.

THE annual report of the health of the Army has just appeared and reveals a slightly higher invalid-rate, a lower number of constantly sick, and an identical death-rate with that of 1925. It was found that officers in India were less well protected by antityphoid inoculation than were the men, although there was an improvement on last year. Injury heads the list of causes of death among "other ranks," followed by pneumonia and diseases of the digestive system. There was a decrease in the number of deaths from both these natural causes. The principal cause of invaliding was middle-ear disease, which remains high and gives some cause for anxiety. Nearly a quarter of all the men invalided during 1926 suffered from ear trouble. The majority of men admitted to hospital were suffering from malaria, which was unusually severe in the Western Command in India. Influenza was very mild and only caused one death, but there were over a thousand more cases than in 1925. An interesting side-result of the coal strike was an increase in the amount of scabies, and the fact that each case lasted half a day longer than usual under treatment. This is attributed to the lack of hot water. Bermuda was the most healthy command and Malaya the worst. Venereal diseases diminished in frequency, but there is still a high incidence about the time of the Christmas furlough, when men expose themselves to infection without the preventive facilities that are available in barracks. It is hoped that a reduction in the incidence and an improvement in treatment may result from careful attention to these facts. The liability of uninoculated men to typhoid fever was seven or eight times greater than that of the inoculated, and the mortality ten times greater. We observed three years ago [1] that there was no discussion on the prevalence of tuberculosis in the reports of either of the three servic This year we note that "the whole subject pulmonary tuberculosis in the services is bei investigated by a special committee and the relati of this disease to service conditions, its inciden invaliding, and attributability will be the subject a report." We hope to deal with the figures of t report more fully in a later issue.

PROTEIN TREATMENT OF DRUG-ADDICTION

ABOUT a year ago A. Lambert and F. Tilne described a new treatment of drug-addiction with preparation called narcosan, which consists of solution of lipoids, non-specific proteins, and wat soluble vitamins. The treatment is based on assumption that narcotics such as morphia cause to bodies to be formed in the body, and that these bod neutralise the narcotic and, in so doing, are themsel neutralised. When the narcotic is withdrawn th toxic bodies cause withdrawal symptoms because th are no longer being neutralised. Lambert and Tiln therefore proposed that when a narcotic is withdra narcosan should be given instead, in the hope th the lipoids which it contains will neutralise the to bodies, and thus prevent symptoms. The authors a recent paper [2] on drug-addiction consider that t results of narcosan treatment are not consistent wi the hypothesis on which it is based, and quote evide to show that drug-addiction is associated with hy function of the endocrine system, secondary possi to disturbance of the sympathetic. According to t hypothesis, withdrawal symptoms are due to a fu tional upheaval in the endocrine system. They st that the results of treatment with various endocri extracts and also by hypodermic injection of solutio of vegetable proteins, which are regarded as stimula of the endocrine system, confirm this hypothesis, a they point out that one of the vegetable prot substances (alfalfa protein) which they used as endocrine stimulant is also present in narcosan. is suggested that the beneficial effects of the lat preparation are due not to its ability to neutral toxic bodies formed in response to the narcotic, b rather to the stimulating effect of alfalfa protein the endocrine system. Acting on this assumption th treated a series of drug-addicts with alfalfa prot and obtained results similar in every way to tho obtained with narcosan. Withdrawal symptoms w slight and the patients remained in good physi condition. It seems probable, they say, that protei prepared from millet, rape, and hemp seed will gi equally satisfactory results, but recommend that forms of protein treatment should be reinforced synchronous administration of orchitic and ovari extracts, on the grounds that sexual function invariably affected in drug-addicts. An advantage alfalfa protein over narcosan is that it is very mu cheaper.

THE INCIDENCE OF GENERAL PARALYSIS

IN view of the reports from all sides which indica that mental disorder of every kind is on the increa in the United States, it is interesting to study t figures for syphilis and general paralysis recently issu by the United States Public Health Service to t Office International.[3] The incidence of syphilis amo the general population is, of course, uncertain, but t percentage of recruits giving a positive Wassermar reaction, out of a group of close on 12,000 in 1916 w 13, and out of 856 candidates for the Washingt police 15. The consensus of opinion puts the figure 10 per cent. for the whole population, but rece research has tended to lower it. The proportion general paralytics to others in mental hospitals seer

[3] Office International d'Hygiène Publique, Bulletin Mensu xix., 11.

gh. St. Elizabeth's Hospital in Washington admitted 58 general paralytics in a total of 26,500 entries tween 1886 and 1924, a percentage of 5·87. In 25–26 the percentage was 12·11. Census returns ve the admission figures over the whole country as 1 per cent. in 1910 and 7·9 per cent. in 1922, though e proportion of general paralytics to other patients tually in hospital in that year was 3·5 per cent. ne number discharged cured was 0·5 per cent.; ·5 per cent. were discharged improved, and 11·1 per nt. unimproved. Of every 100 dying in hospital ·5 were general paralytics and 14·54 were sufferers om cerebral syphilis. The returns of 29 State ental hospitals for 1925 showed a percentage of 3·1 admissions for syphilitic psychoses, the individual gures varying from 1·8 to 28·5 per cent. The gistration bureau shows the proportion of deaths from philis to have remained at about 8 per 100,000 of pulation between 1914 and 1924; deaths from neral paralysis were approximately 7 per 100,000 ring each year of the war, under six in 1919 and 1920, d about six and a half from 1921 to 1924. Treatment malaria seems to have yielded better results than ost workers in this country dare to claim, for the gures given for the total remissions vary between and 70 per cent. Although the census returns do not ow a decrease in the incidence of general paralysis any medical sources report a decline, and this, if tual, should make itself felt on the official returns ter about five years. The incidence figures for venile general paralysis are small. In 1910. out 60,769 admissions to U.S.A. mental hospitals, only 7 patients under 15 were diagnosed as general ralytics. P. C. Jeans and J. V. Cooke, who examined ne-fifth of all the infants born in St. Louis during a rtain period in 1921, put the incidence of congenital philis at 3 per cent., but out of the children of 96 families examined between 1910–21 P. J. White nd B. Veeder only saw two cases of general paralysis nd two of tabes dorsalis. In this country in 1925 ne number of patients resident in mental hospitals as 106,403, and the death roll was 8029. The number general paralytics admitted in that year was 1218, 1·14 per cent. of the residents; the number of those ho died was 1174, or 14·1 per cent. of the total deaths. ssuming a population of 45 million, the number of eaths from general paralysis is therefore about ·6 per 100,000, a figure considerably lower than the ·4 of the U.S.A. census for 1924, and the other gures are well below the corresponding ones furnished y the American census. The inference is that general aralysis, in common with most other mental and ervous conditions, has a higher incidence in the Jnited States than in this country, but the reasons for his are not as obvious as for the greater prevalence of sychogenic disorder.

Other figures, quoted by Dr. P. L. McKinlay in a aper on the relative incidence of general paralysis nd locomotor ataxia among different social classes,[4] ive the average death-rate from general paralysis as ·07 per 100,000 during the three-year period 1910–12, or which the American figure is only 6·3. Contrary to he usual belief, Dr. McKinlay finds that general aralysis is proportionately more frequent in the ower than in the upper occupational classes. This ight seem to dispose of the theory that this form of euro-syphilis is determined largely by excessive rain-work. It has long been suspected that some aw, and not mere chance, governs the form which ertiary syphilis shall take in a given patient, and it as Dr. McKinlay's object to discover, if possible, the ignificance of occupation and other social factors. Ie quotes the conclusion of Mott that stress on those arts of the nervous system that are most in use is an mportant element. In a majority of general para- ytics Mott found that the gross wasting of the left erebral hemisphere was greater than that of the right, nd out of 60 successive such cases of tabes dorsalis nly two were not engaged in occupations involving tress of the lower limbs. The fact that his statistics prove the opposite of the popular view may, he thinks, be due to error in the premises on which that view is based. Statistics derived from general hospitals on the social incidence of disease are apt to be vitiated by the selective methods employed. Perhaps the most telling argument, however, against the general impression is that it leaves out of account a host of factors like alcohol, which according to Mott, favours the onset of general paralysis while it merely accelerates tabes, and the higher incidence of syphilis among the lower strata of the population. Only when statistics are modified by this factor will they have any real value.

[4] Jour. of Hyg., 1928, xxvii., 174.

TANNIC ACID IN THE TREATMENT OF BURNS.

THE suffering caused by extensive burns is so intense and the danger to life is so grave that medical men cannot rest satisfied with the means at their disposal for treating the victims. We publish on p. 336 an article by Dr. R. M. Gordon on the use of tannic acid, which in his experience efficiently combats toxæmia by preventing the absorption of toxic products, as well as soothing pain and lessening scar formation. In a recent issue of the *Canadian Medical Association Journal* (1927, xxii., 1357) Dr. John Hunter records the case of a girl who was severely burned on the face, neck, and arms as the result of a gasoline explosion. The fire brigade applied a first-aid dressing of picric acid and a young doctor removed this and substituted carron oil. Next morning Dr. Hunter found that the carron oil dressing was causing intense pain and profuse discharge. He therefore sprayed on a watery solution of 2½ per cent. tannic acid, leaving a coating a quarter of an inch thick. No bandage was used and the acid was left to peel off, which it did in about three weeks' time. Relief was instantaneous and the discharge was lessened. Although pus oozed out from under the dressing there were no toxic effects. Shock was minimised by heat, stimulants, rest, and diathermy, and as soon as possible the affected areas were exposed to sunlight. The result was eminently satisfactory, and Dr. Hunter concludes that tannic acid is the treatment of election for burns.

THE MOTT MEMORIAL.

THE response made to an appeal by the Council of the Royal Medico-Psychological Association to the colleagues, friends, admirers, and former pupils of the late Sir Frederick Mott, for their coöperation in the publication of a Memorial Book has been such as to encourage the Council to proceed with the proposal. The Council has appointed a Memorial Committee consisting of Dr. C. Hubert Bond, Dr. F. L. Golla, Dr. Douglas McRae, Dr. Thomas Beaton, and Lieut.-Colonel J. R. Lord (hon. secretary). Neurologists, psychiatrists, and pathologists in Canada, the United States, and Japan, as well as in this country and on the continent of Europe, have promised to contribute papers to the Memorial Book, which promises to be of high intrinsic scientific value and should worthily perpetuate the memory of one who did so much to elucidate the dark corners of neuropathology. The Committee have opened a fund which will be devoted primarily to the publication of the Memorial Book. Donations should be sent to the Treasurer, Dr. James Chambers, The Priory, Roehampton, London, S.W. 15. A donation of not less than 18*s.* 6*d.*, if subscribed before publication, will entitle the donor to a free copy of the work when it appears.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: CONFERMENT OF HONORARY FELLOWSHIPS.

THE Royal College of Physicians is celebrating on May 14th next and following days the tercentenary of the publication of William Harvey's book "De Motu Cordis," an event that laid the foundation-stone of modern physiology and scientific medicine. Delegates and distinguished guests from all parts of the world have been invited to participate in an interesting

programme of scientific and social gatherings. The College is reviving on this occasion an honour that has been bestowed but seldom in the four centuries of its existence, by electing to its honorary Fellowship the Earl of Balfour, Sir Ernest Rutherford, and Profs. Ivan Pyotrovitch Pavloff and Karl Friedrich Wenckebach, each of whom has rendered signal service directly or indirectly to the advancement of medical science.

The Royal College of Physicians of London has issued a card of lectures to be delivered at the College in the coming spring. On March 1st, 6th, and 8th Dr. F. A. E. Crew will deliver the Milroy Lectures on Individual, Familial, and Racial Inborn Differences in respect of Immunities and Disease Resistance. On March 13th, 15th, and 20th, Dr. T. Izod Bennett will deliver the Goulstonian Lectures on Some Problems of Nephritis. On March 22nd, 27th, and 29th Dr. James S. Collier will deliver the Lumleian Lectures on Epilepsy. On May 1st and 3rd Dr. E. P. Poulton will deliver the Oliver-Sharpey Lectures entitled an Experimental Study of Certain Visceral Sensations. On June 5th, 7th, and 12th Dr. Charles Bolton will deliver the Croonian Lectures on the Interpretation of Gastric Symptoms. Any member of the medical profession will be admitted to these lectures on presentation of a visiting card.

DRUGS BEFORE ANÆSTHESIA.

THE advantages of using hypodermic injection of various drugs before the administration of anæsthetics are not admitted by everyone. There are anæsthetists who never employ this "premedication," and there are surgeons who strongly object to it, believing that muscular relaxation is often deficient during operation when premedication is employed, and that convalescence is delayed. They question whether the action even of atropine may not interfere with the proper and speedy elimination of the anæsthetic. Nevertheless on the whole opinion appears to favour the use of preliminary hypodermic medication, although there is considerable variety in the drugs and doses recommended. From the point of view of the patient's comfort there is often undoubted advantage. The gain to a highly nervous, frightened, or restless patient from a sedative injection of scopolamine with morphine or omnopon is so great that it generally outweighs possible difficulties. The enthusiasts for preliminary medication make claims, however, that are scarcely justified in practice. It is said, for example, to "abolish all psychic impulses, maintain the normal ratio between respiration and circulation, render shock less liable both during and after operation, shorten the period of convalescence," and usually to prevent nausea or vomiting. This is surely an overstatement. Some experimental work recently recorded by J. T. Gwathmey[1] appears to show, as far as it goes, that in rats, at any rate, preliminary medication does exercise a protective influence on the tissues of the lung. Sulphate of magnesium (2 c.cm. of 50 per cent. solution) is the drug most approved of by this authority, and he uses it in conjunction with small doses of morphia.

[1] Amer. Jour. Surgery, December, 1927.

SUSSEX PROVIDENT SCHEME.—During the seven years of its existence, no less a sum than £33,534 6*s.* 2*d.* has been paid to the coöperating hospitals and authorities on account of services rendered to members of the Sussex Provident Scheme. From the sum of £332 17*s.* 3*d.* in 1921, the total has increased by leaps and bounds each year, the total paid over for 1927 being £9287 17*s.* 9*d.* In this latter year the Royal Sussex County Hospital received £4434 8*s.* 4*d.*, and other large amounts included: Royal Alexandra Hospital for Sick Children, £914 9*s.* 3*d.*; New Sussex Hospital, £887 17*s.* 3*d.*; Sussex Maternity and Women's Hospital, £544 9*s.* 1*d.*; and Brighton and Hove and Preston Dispensary, £540 9*s.* 3*d.* The poor-law authorities received £265 13*s.* 8*d.*, and the sum of £258 17*s.* 9*d.* was refunded to subscribers for treatment at non-coöperating hospitals and benefits under the supplementary section.

Modern Technique in Treatmen

A Series of Special Articles, contributed by invitatio on the Treatment of Medical and Surgical Conditio

CCLXIII.—THE TREATMENT OF LICHEN PLANUS.

Lichen planus may be of the most trivial impo as regards its effect on the patient or may be one the most distressing diseases. It may begin gradual and insidiously or acutely, but I do not think ever disappears very quickly. At the outset, therefor it is well to treat every case with caution, as it ma be difficult to tell, even in the presence of an apparent mild case, whether one may not be confronted rath suddenly by a serious outbreak.

The treatment may be divided primarily into th aimed at suppressing the disease as a whole measures which may be called constitutional, a the purely local measures designed to allay discomfo and disfigurement. As a matter of fact, there some overlapping of these measures, since liche planus is one of the diseases in which local traumatis determines in a striking measure the appearance new lesions.

Constitutional Treatment.

In determining the seriousness of the attack I thin attention should be paid chiefly to the presence absence of itching, and its degree when presen In the more moderate cases where itching is n extreme in its severity one may choose as the for of constitutional treatment the administration drugs. Of these, two stand out pre-eminently namely, mercury and arsenic—though opium an drugs of the phenazone group are often useful addition. If the itching be fairly severe and th eruption be coming out acutely, it will be better avoid arsenic and to rely on mercury, combined not with one of the above-mentioned sedatives.

The time-honoured liquor hydrargyri perchlori introduced by Liveing is extremely valuable a may be given in doses of ½ to 1 drachm three tim a day. Of recent years, however, I have bee greatly struck with the efficacy of the yello mercurous (not mercuric) iodide, which may given in doses of an eighth of a grain three times day, preferably between meals. If sleep is muc broken a dose of opium, say, tr. opii ℥xv., may given at night for a time.

As soon as the more acute phase of eruption a the irritation subside, this treatment may be change and arsenic substituted, and arsenic may also used by the more experienced from the beginnin where itching is absent and the type of eruption n very fiery. It may be given as liquor arsenical (℥v., t.d.s., post cibos), and, in my experience, is efficient in this way as in any other, unless the patie has an irritable alimentary tract and is unable tolerate arsenic by the mouth. In this case one ma resort to injection, and the most approved form recent years is the drug known as acetylarsan. may be given in doses of 3 c.cm. (equal to 0·7 of the salt) twice weekly, up to 15 injections.

In very severe cases, where itching is intens sleep almost entirely lost, and the patient's conditio threatening, I can confidently recommend the trea ment introduced by Thibierge and Ravaut, of lumba puncture and the withdrawal of from 6 to 8 c.cm of the cerebro-spinal fluid. In almost every cas in which I have used it the result has been dramati and not infrequently the whole aspect of the cas has changed within 24 hours, the maddening itchin subsiding, and sleep being restored.

It should never be forgotten that the nervou condition is almost invariably unstable in seve lichen planus, and that insomnia not only distresse the patient but aggravates the eruption. I invariabl keep my patients in bed for 48 hours after the trea ment by lumbar puncture, but, as a rule, in a cas

ere enough to demand this form of treatment the tient should be kept in bed in any case.

Lastly may be mentioned, as having a somewhat ilar effect, the radiation of the spine with X rays, a stille dose being given through an aluminium filter. ry strong claims have been put forward in favour this form of treatment, but I have not used it as does not appear to be so rapid in its action as the thdrawal of cerebro-spinal fluid, and I feel that are more absolutely certain that the latter does insidious damage.

Local Measures.

The local treatment of the more recent case depends the form of the eruption. Where the typical ne papule is present alone I find that lotions act tter than ointments, as the latter give a feeling of at. I generally find either liq. picis carbonis 2 per nt. in lotio calaminæ, or the following lotion icacious :—

enol cryst.)		Sp. vini meth. indus-	
mphor)	āā ℥ ss.	trialis	℥ iv.
drargyri perchlor.	gr. i.	Glycerini	℥ i.
tv. tragacanth. ..	grs. xv.	Aq. destill. ad ..	℥ viii.

In some cases and at some stages the horny licular papule is the chief lesion, and in such I find e following ointment useful :—

id. salicyl.	.. grs. xxv.	Ol. olivæ	℥ i.
pon. mollis	.. ℥ ii.	Adip. lanæ ad ..	℥ i.

is should be thoroughly rubbed in once a day and shed off before applying afresh.

Verrucose Patches.

Lastly must be mentioned the verrucose patches ually seen on the limbs and chiefly below the knees. ch patches seem to have little or no tendency to ontaneous cure and may last for many years if treated. Sometimes they are very irritable, at hers merely disfiguring. Many forms of treatment ve been recommended for them, and it is usually lieved that constitutional treatment is without ect upon them, though I have seen them flatten wn and disappear in a remarkable manner after mbar puncture.

The local treatment recommended includes that X rays, by freezing with carbon dioxide snow, and en destruction with the actual cautery. All of ese are unsuccessful at times, though one or other ay occasionally succeed. Of recent years, however, have had remarkable success by the following ethod. The patch is thoroughly rubbed in with ie following ointment :—

enol cryst.)		Ung. hydrargyri ..	℥ ii.
mphor)	āā grs. xxv.	Adip. lanæ ad ..	℥ i.

a area larger than the patch is then covered in th zinc oxide strapping, which, of course, adheres dly at the edges beyond the greased area, but eps the whole area, as it were, locked up in a water- oof dressing. It should be renewed daily, and should excite some inflammatory reaction it should be opped for a time and the part soothed down with ad or calamine lotion, and then reapplied after the action has passed away.

ARTHUR WHITFIELD, M.D., F.R.C.P. Lond.,
Consulting Physician to the Skin Department, King's College Hospital; and Emeritus Professor of Dermatology, King's College, London.

GLASGOW DENTAL HOSPITAL.—At a meeting in aid the building fund of this institution it was stated that e Dental Board of the United Kingdom had granted 000 towards the fund, £1000 of which is for equipment. r Holburt Waring, treasurer of the Dental Board, said at the work of the staff had to be done in "a derelict velling-house," and Dr. A. S. M. Macgregor, the Glasgow edical officer, added that the premises were insanitary id that it was impossible to make any provision for dental search.

The Services.

ROYAL ARMY MEDICAL CORPS.

Capt. J. C. Burns, half pay list, late R.A.M.C., retires on retd. pay on account of ill-health contracted on active service.

Lt. (on prob.) W. R. C. Spicer, from the secd. list, is restd. to the estabt.

TERRITORIAL ARMY.

Maj. H. E. S. Richards, having attained the age limit, is retd. and retains his rank with permission to wear the prescribed uniform.

Lts. E. Holmes, F. A. Smorfitt, and F. C. Lewis to be Capts.

Lt. J. S. Fulton, late R.F.A. (Spec. Res.), to be Lt.

A. C. King to be Lt.

Supernumerary for service with O.T.C.—Capt. W. R. Martine, from Gen. List, T.A., to be Lt., supern. for serv. with Med. Unit, Edinburgh Univ. Contgt., Sen. Div., O.T.C., and relinquishes the rank of Capt.

ROYAL AIR FORCE.

The undermentioned Flying Officers are promoted to the rank of Flight Lt. : G. E. Church and E. J. Jenkins.

Flight Lt. G. J. Griffiths is transferred to the Reserve, Class D.ii.

INDIAN MEDICAL SERVICES.

Lt.-Col. A. W. C. Young retires.

Lt.-Col. G. W. Maconachie to officiate as Inspector-General of Prisons, Bihar and Orissa. Lt.-Col. C. A. Sprawson, Principal, King George's Medical College, Lucknow, has been appointed a Member of the Board of Public Health, United Provinces, vice Dr. Saiduz-Zafar Khan, resigned. Lt.-Col. W. L. Harnett has been appointed to act as Professor of Surgery, Medical College, Calcutta, and Surgeon to the College Hospitals, vice Lt.-Col. Sir Frank Connor, granted leave. Dr. Rai Satish Chandra Banerjee Bakadur, Assistant Prof. of Physiology, Medical College, Calcutta, has been appointed to act as Prof. of Physiology of that Institution, vice Lt.-Col. A. C. MacGilchrist, retired. Dr. H. S. Dube, M.O.H., Delhi, has been appointed M.O.H., Lucknow. Dr. J. Misquitta, officiating M.O.H., Lucknow, has been appointed M.O.H., Dehra Dun, vice Dr. Bishan Dayal, appointed Assistant M.O.H., Unao. Lt. J. T. Stuart has been appointed to the Subcharge of the Dermatological Ward, British Hospital, Secunderabad. Lt.-Col. W. T. McCowen to Command Indian Military Hospital, Dehra Dun. Maj. F. W. Hay to be 2nd in Command, Indian Military Hospital, Dehra Dun. Dr. Pareshchandra Guha, Civil Asst. Surgeon, has been appointed to hold medical charge of the Sadr subdivision of the Kamrup District. Lt.-Col. S. R. Godkin to be Officer Commanding, Indian Military Hospital, Jullunder, vice Capt. S. Dutt. Capt. S. Dutt to be 2nd in Command, Indian Military Hospital, Jullunder, vice Capt. D. R. Tharpar, vacated. Maj. A. A. Kernahan to be 2nd in Command, Indian Military Hospital, Peshawar. Lt.-Col. R. C. McWatters, Civil Surgeon, from Nani Tal to Agra. Dr. Hafizullah Khan has been appointed to be temporary Assistant M.O. on Cholera Research Work, vice Dr. Muhammad Abdul Hadi.

COLONIAL MEDICAL SERVICES.

Dr. W. C. Smith, medical officer, to be Medical Officer of Health, Nigeria; Dr. G. V. Allen, senior bacteriologist, Kenya, to be Bacteriologist, Institute for Medical Research, Federated Malay States; and Dr. H. C. Wilkinson, medical superintendent, King Edward VII. Memorial Hospital, Bermuda, to be Director of the Medical and Health Department, Bermuda.

The following appointments have been made during the month which ended Jan. 31st: Capt. J. M. Wallace, Bacteriologist, Trypanosomiasis Research, Uganda; Mr. H. M. Soar, Mr. D. W. McLaren, and Mr. F. Kane, Medical Officers, West African Medical Staff; Miss E. M. Stratton, Lady Medical Officer, Gold Coast; Lt. C. W. Hope-Gill, Medical Officer for Tsetse-fly Investigation, West African Medical Staff, Nigeria; Miss J. R. Mason, Lady Medical Officer, Gold Coast; Mr. W. H. Emslie, Medical Officer, West African Medical Staff; Mr. A. C. Lovett-Campbell, Medical Officer, West African Medical Staff; 2nd Lt. H. C. Curtis, Medical Superintendent, King Edward VII. Memorial Hospital, Bermuda; and Miss E. A. Robertson, Medical Inspector of Schools, Federated Malay States.

JOHN HUNTER:
BICENTENARY CELEBRATION.

The Bicentenary celebration in honour of John Hunter followed the programme issued earlier by the Royal College of Surgeons of England. During the week the Hunterian Oration was delivered at the College by Sir Holburt Waring and the Thomas Vicary Lecture by Dr. G. C. Peachey. These will be found in our columns. Demonstrations were given daily by the Conservator of the Museum, Sir Arthur Keith, and the Librarian, Mr. Victor Plarr, and the Festival Dinner was held at the College on the night of Feb. 14th, the President, Sir Berkeley Moynihan, presiding.

We publish below a series of letters of extreme interest to all students of medical history, and especially of the lives of John Hunter and his elder brother William. They have been entrusted to us for publication by Dr. Louisa Hamilton.

THE HUNTERS AND THE HAMILTONS: SOME UNPUBLISHED LETTERS.

ANYONE who opens the calendar of the University of Glasgow will discover that its chair of anatomy was occupied by a dynasty of Hamiltons during the latter half of the eighteenth century. The chair was filled by Dr. Robert Hamilton from 1742 until 1756. He was the eldest son of William Hamilton, the minister of Bothwell, and was born in 1714. The manse of Bothwell and the farm of Long Calderwood, the home of the Hunters, were all within easy reach of the town of Hamilton, where the great Dr. William Cullen commenced the practice of medicine in 1736. Cullen was the friend and mentor of both the Hamiltons and the Hunters.

Turning again to the calendar, we find that a second Hamilton—Dr. Thomas Hamilton—occupied the chair of anatomy from 1757 until 1781. He also was a son of the manse of Bothwell, and the youngest brother of Dr. Robert Hamilton, whom he succeeded. He is a figure of importance to all students of John Hunter's history, for when John Hunter set out on horseback to join his brother William in London in September, 1748, being then in his twenty-first year, he was accompanied by a "Mr. Hamilton," who joined him at Bothwell. We know that Thomas Hamilton, the future professor, came to London in the autumn of 1748, and during the winter 1748–49 worked in William Hunter's dissecting-room—beginning his dissections at the same time as John Hunter. Sir Arthur Keith feels certain that it was this Thomas Hamilton who rode side by side with John Hunter for the 15 days occupied by the journey from Glasgow to London.

Dr. Louisa Hamilton, a living descendant of Thomas Hamilton, has just brought to the light of day two letters, written to him by his father, the minister of Bothwell, in 1748 and 1749, when he was studying in London. She also owns the 11 letters, most of them addressed to Prof. Thomas Hamilton, by his son, William Hamilton, who later succeeded him in the professorial chair at Glasgow.

Dr. Thomas Hamilton, after studying with William Hunter—who cited him as a witness when he accused Monro, of Edinburgh, of plagiarism in 1763—returned to Glasgow and succeeded to the chair of anatomy as the second Hamilton professor. Dr. William Hamilton succeeded his father Thomas in 1781, but overworked himself and died in 1790—at the a of 32. As a young man, this third Hamilton follow in the footsteps of his father—coming to Lond at the end of 1777 to study with both William a John Hunter. The charming and informative lett which he then wrote to his father and to his moth make up the greater part of the series whi THE LANCET has now the privilege of publishin through the courtesy of Dr. Louisa Hamilton.

Below is the anatomical dynasty of the Hamilto but the subsequent history of the family is interestin The third anatomist professor left behind him t young boys; the elder became Sir William Hamilto the pride of Scottish philosophy; the young Thomas, made his mark as a successful auth The great philosopher had three sons; the eld became Sir William Stirling Hamilton, who made name during the Indian Mutiny, and his son is t present baronet. A younger son, Hubert, was t father of Dr. Louisa Hamilton, who, with gre generosity, has presented the letters here reproduce with several others, to the Council of the Roy College of Surgeons, England. Dr. Louisa Hamilto has been entrusted quite lately with a cabin which she found to be packed with old fam correspondence, among which she discovered t 11 now published for the first time.

If we take the letters in the order of their dat they fall into three series. There are (1) the t letters written from the manse of Bothwell in t winter, 1748–49, to Thomas Hamilton in London; there are 11 letters, published herewith, writt 30 years later—1777–78—to Thomas Hamilton a his wife by his son William, just as he commenc his medical studies with the Hunters; and (3) th letters written by John Hunter (1783–88) when t great surgeon had reached the height of his fame, his old pupil William Hamilton, when the latter w achieving success as professor of anatomy in t University of Glasgow. These three letters will, trust, be published later.

SIR ARTHUR KEITH'S COMMENTARY.

Upon the whole correspondence, but especia upon the letters which follow, Sir Arthur Ke writes the following commentary:—

"What I have been hoping for in past years that chance would bring to light letters writ by Thomas Hamilton in the winter of 1748–49, wh he was a fellow-student of the raw John Hunter, j freshly arrived from Scotland. I have not lost hope

Rev. William Hamilton,
Bothwell Manse.

Robert Hamilton
(Professor of Anatomy, 1742–1756).

Thomas Hamilton
(Professor of Anatomy, 1757–1781).

William Hamilton
(Professor of Anatomy, 1781–1790).

Sir William Hamilton
(Philosopher).

Captain Thomas Hami
(Littérateur).

ther letters, but in the meantime we have now two ters—not yet released for publication—addressed him at this date by his father, the minister of thwell and owner of the estate of Airdrie. The st of these letters is dated 1748 and is directed to 'homas Hamilton, Surgeon, going to London.' ritten in pencil on the outside, is a ' direction,' ly imperfectly legible now, ' Dr. Ross at the red np, over the saddlers . . . further side of Leicester elds.' This letter and the other begin, ' My dear m '—warm-hearted, fatherly letters, which I hope . Louisa Hamilton will publish in full some day. the meantime she has given us enough to be going with. These earliest letters, written by an cestor six generations removed from her, show that the Rev. William Hamilton was an ancestor be proud of.

" We now come to the second and most important ies of letters, written in the winter of 1777–78, ien the War of Independence was being fought in nerica. Prof. Thomas Hamilton was then 51 years age and had occupied his chair during 20 of them. s son William, the writer of the letters, was at is time 19; at 17 he took his degree in arts at e ' College ' of Glasgow, and then went to Edinburgh study medicine for two years. His first letter is itten from Bath on Nov. 23rd, 1777, and is addressed his mother in Glasgow. We gather that his father, of. Thomas Hamilton, has been ill, and has been vised to seek treatment at Bath, whither his son d convoyed him before setting out to begin his udies in London under Dr. William Hunter. Almost e first sentence tells us we have made the acquaint-ce of a dutiful son."

ETTER Professor W. Hamilton to his Mother: Dated 23rd Nov. 1777:

BATH Novr. 23 1777.

y Dear Mother

We had this morning the pleasure of your Londonian ravan (as Dr. Stevenson calls it) which made us excessively ppy, and me particularly so to hear from your own hand at you were well. The praises you have bestowed on me all my father's letters (which I have read) and those u were so good as give me in my own one, make me very oud. I must however say that what I have done does not erit them, as it was only an attempt to show my father d you the sense I had of the benefits I have received m you and repaying in a small degree the care and atten-n you have ever shown me, and even gives me pleasure think that an opportunity has occurred that I might ow my gratitude to you by being of use to my father. ver since we set out it has always been my business to do erything I thought he would like and even to prevent s asking me and his will therefore has been entirely mine d from the time we left you which is near six weeks I nnot say my father ever has given me a sour or angry ok much less quarreled me for any thing I had done. y Father I need scarce tell you is getting better every day d walks full as well as he did when he was beginning to out with his last sore leg. He is perfectly independant my assistance so much so that once or twice he has got before me (I rose at nine) put on all his cloaths and ne to the pump room, and behold when I came to raise m he was gone, to my great amazement the first time. r. Trollope who is a vastly good kind of man and very greeable, tells my father he thinks in a month or two he ill walk down to Scotland. He has got nothing done about s wig yet and I have been preaching up to him to get a w one. I wish you would second me. I did not go to the all on Friday. You ask me if I have been at the rooms, that I fancy you mean the ball as at other times nobody es but subscribers where they game or walk about there e few people go there but gamblers and old ladies (who e the bye are mostly notorious cheats) and no party is ayed there under half crown whist or shilling quadrille, d in the card room at the Ball I was at a french duke d an english one were laying fifty and a hundred pounds the hands—so great a sport of gaming is there at Bath. ovr. 24.—I delayed closing my letter till to day in case y thing happened worth writing you. Dr. Gusthart has lled twice on my father and we are to dine with him on ursday next. I wish your intelligence about Mr. ennistowns coming to Bath may be true. I intend writing Brown next packet as this one will not hold what I ve to say to him.

elieve me ever to be My Dearest Mother your
Dutiful son &c.
" W. HAMILTON "

P.S. Present my Dutiful compts. to My Aunt and Mr. Ritchardson and all my friends and acquaintances.
" W.H "

As I find I have enough of time and a great inclination to continue I will not end where I intended. I have been straying on the Banks of the avon to find Mr. Simkins muse (which it is with great probability supposed he left at Bath.) But as I have been unlucky in that attempt I shall take a plunge in the Bath and see what that may do as my father has sent Mr. R. a poem whether of his own or not I shall not determine. We have no news here the Quid nuncs of this place are abusing government and the indispensible for sending their expresses by vessels of no force for they make no doubt but the packet with the news is taken. The Bells are just begun to serenade us, some great man has arrived, it is one of the most infernal noises imaginable we are close by the abbey and to have 10 bells ringing chimes at once is disaggreeable beyond any thing you can conceive.

Adieu my Dear Mother.

" Young William Hamilton set out from Bath, where he left his father, the professor, to take up his medical studies in London on Dec. 16th, 1776. Before starting he wrote another letter to his mother which contains things worthy of record here, particularly his reflections on the young clergymen whom he found frequenting the gaming tables at Bath."

LETTER Professor W. Hamilton to his Mother: Dated 6 Decr. 1777:

BATH Decemr 6 1777.

My Dear Mother

We on Monday had the pleasure of your letter which made us I assure you very happy and we wait with impatience for your Sundays packet. My Father continues mending and except his bending the knee of his left leg a little when he walks, walks almost as well as ever he did, he is been perfectly well since I wrote you he does not find any sourness of his stomach since he came here, and eats pretty well. He drinks every day a pint (mutchkin) of porter and except that, never tastes any thing stronger than water or small beer, the Drs. have pressed him to drink a little wine which he has absolutely refused. We this day lost Mr. Trollope which I am very sorry for he was a very merry kind of man and was the life of our company. We have got a scotch Dr. from Exeter called Ker and a lady with him whose name I do not know they dined with us yesterday for the first time the old lady does not seem to want the gift of the Gab.

I go off for London the week after next I wish you had sent Mr. Young's direction. I wrote twice to George Reid to send it me but have heard nothing from him so that I must just stay in the inn in London till I can find some of my acquaintances out and get a room. I am sorry to hear the bad news from G. Burgoyne I hope Bob Buchanan or Billy Cullen were not with him besides many killed three entire regiments are cut off to a man, and the rest have laid down their arms. One of the gentlemen of our house gained the spray of Myrtle at Batheaston I saw his poem, it is indeed a very poor one not much better than our greek class productions and if this is the best what must the worst be, but in all these prizes favour goes farther than merit. I was at the Ball on Monday and at the play on Thursday I was amazed to find that the young clergymen here dance and play at cards in the public rooms but I find now that there are among them who are remarkable for gambling and every kind of vice and that there is but one part of a bucks character they carefully avoid and that is fighting which it is said they have a mortal aversion to; a man must have a pretty modest assurance to preach against vices on Sunday which have been his sole employment thro the rest of the week, this character I would fain hope is not a just one all I can say is I had it from a gentleman when I expressed my surprise at their openly playing at cards with people who seemed to be playing high. We saw Mrs. W. Bogle and her daughter to day they are both very well, Miss Bogle I think is very pretty. There no word yet of Mr. Houston so I cannot write my aunt to thank her till I get my buckles, if they come after I leave Bath my father will take care of them and bring them down as I shall have no use for them in London.

Decemr 7th. I am happy to tell you a piece of news which I hope true, my father has got acquainted with a gentleman in his situation from barbadoes and a surgeon, who told him that on friday last he dined in Bristol with a gentleman from Halifax who left it the 2 of Novr and who said the day before he left it dispatches had come there from G. Burgoyne who had pushed his way to Albany and where he said he hoped he would be able to open a communication to N. York and keep it up thro the winter, in this case the defeat of Burgoyne is a story made up by the three deserters

who were the only authority for it at Quebec, the gentleman says his friend is a man of veracity and the present bad news is not at all believed at Bristol. I was at the Abbey to day and heard the Bishop of Bath and Wells. Do not forget to read our Bristol news to professor R. I won't write it him as I know it would grieve his righteous spirit. My Father was out in a chaise with Mr. Trollope last week and he and I will go out some day this one, it is very cheap you have a chaise for 3 hours for 5 shillings. We have a flaming paragraph in the Bath papers of the honors shown Dr. Graham at Glasgow (he is now here and probably put it in himself,) they say he had the freedom of the town and a fine entertainment given him. I shall write you whenever I get to London. Dr. Gusthart would take no fee from my father. Present my dutiful compliments to my aunt and remember me kindly to all my friends and acquaintances. I need scarce subscribe myself (for you will know my hand) your dutiful son

"W. HAMILTON"

P.S. I have enclosed a letter for Miss Brisbane pray seal it up and send it as soon as possible.

"On Dec. 18th, 1777, he reached London at 3 o'clock, having seen 'Windsor Castle and passed thro Eton where the great school is.' The journey cost '3 pound, 7 shillings,' but he still had in his pocket, so he informs his father, 'two guineas and some shillings.' He had also 'draughts on Mr. Coutts.' On his arrival he had to put up at the 'Golden Cross,' Charing Cross because his two Glasgow friends, Mr. Young and Mr. George Reid, who were studying with the Hunters, had 'disappointed him,' neither having given him their 'proper direction.'"

LETTER Professor W. Hamilton to his Father: Dated 18 Decr. 1777:

My Dear Sir

I arrived here about 3 o'clock we dined at Hounslow: I went immediately on coming, to call on Mr. Young and Mr. Rix was so good as go along with me but could find no such person there the woman began to scold us for calling as she said she had had five people this very day enquiring for the same person we then tried No. 3 old round court and with the same success. I immediately determined to go to Dr. Hunters, and ask for the servant that waits at the class door and see if we could know from him the proper direction. We went there and he said he knew both Mr. Young and Reid and could be sure Mr. Reids direction, he came out and a young man with him (probably Mr. Cruikshanks[1]) who told me Mr. Reid had left that only a few minutes before and that he lived in Queens street east at the very end of it and I begged he would tell Messrs. Reid or Young if he saw them to night, if not to morrow morning that I wanted them and would be glad to see them at the Golden Cross which he said he would do. What made me think he was Mr. Cruikshanks was his asking if my name was not Hamilton as he said Mr. Reid had mentioned my intention of coming to town to him and asked if I had not letters for Dr. Hunter I told him I had, but had them not on me that I could not call then as I was just come to town but would do myself that pleasure very soon. We then went to Georges lodgings which were at least two miles off up across oxford road and beyond Cavendish square, he was not at home but they would tell him that I wanted him (if he came home soon enough) to supper if not to morrow morning. We came back to Oxford Road and took a coach to the Golden cross where I stay all night and Mr. Rix went home. Our journey came in all to about 3 pound 7 shillings. We saw Windsor castle to day and passed thro Eton where the great school is. I have still 2 guineas and some shillings. This is an amazingly large town and vastly well lighted for these are the only two observations I have had time to make yet. I hope you do not feel yourself lonely since I have left you. I hope we shall meet in a short time and by that time you will be in a great measure well.

I felt very much on parting with you tho for so short a time and the pleasure I shall feel on seeing you again is the only thing that makes me happy. I wished I had stayed a little longer with you that morning as the inn was locked up when I went and I and the driver (for the chaise just came at the same time) had to rap with our heels at the Gate for ten minutes. Present my compts. to all the family and Believe me ever to be your dutiful son and humble servant

"W. HAMILTON"

Golden Cross Charing Cross
LONDON
Decr. 18 1777.

[1] His guess was right. William Cruikshank, of Glasgow, became assistant to Dr. William Hunter in 1771, was at first an inmate of Dr. Hunter's house, a most accomplished anatomist, and later was friend and surgeon to Dr. Samuel Johnson.

"Note the letter, written to his father on the day of his arrival in London, Dec. 18th, 1777, is subscribed 'Believe me ever to be your dutiful son and humble servant, W. Hamilton'—a subscription which modern fathers have seldom the pleasure of reading."

"Next day, Dec. 19th, he again writes to his father, informing him that he has obtained lodging in Queen-street, Golden-square—close to Dr. Hunter's school in Windmill-street, and that it was necessary to 'direct' to him, 'at No. 26 (brass plate) Queen's Street Golden Square.'"

LETTER Professor W. Hamilton to his Father. Dated 19th Decr. 1777:

My Dear Sir

I wrote you and my mother last night of my arriva in town and of my ill luck in missing Mr. Reid and Young But just after I had sent off your letter Mr. Reid came in and supped with me. He advised me to board at first as the people were apt to impose on a stranger he recommended me to a house where he had been recommended himself by Mr. D. Drummond and where he had staid six weeks but left it as he thought he could live cheaper. This morning he and Mr. Drummond called on me and we went and looked at it it is kept by two old ladies one a Mrs Wilkes and the other her sister the terms are a guinea week for breakfast dinner tea and supper a neat little room and a light closet it is in the second storey and the only thing we must pay for besides is fire. I accordingly took the room for a month till you come to town. Mr. Young called on me to day and said this house he had marked out for me. It is in Queens street golden square and not farther from Dr. Hunters than you are from the pump room, as the street goes off windmill street opposite to his house I have not waited on Dr. Hunter yet nor Mr. Hunter[2] find it is not customary to dissect without attending the class and that I may take out a ticket now which will serve me till the same lecture in the next course as the Dr. has a month of this course to go thro. Mr. Hunter has only one set of lectures in the winter he only reads three a week so that if I enter now I will only lose four and twenty lectures and he does not finish till Aprile, this loss Mr. Young has offered to make up from his notes. But of these things I can write you more fully to morrow after seeing the Hunters whom I delayed calling on to day till I got money for one of my draughts as I must probably fee him just now and Mr. Drummond is to attend me to Mr. Couts to morrow morning with whom he is acquainted. Mr. Cruikshanks I hear is very ticklish with regard to his wife and is ever cast out with Mr. Young who he thought came too often to visit him, but this I beg you will take no notice of and burn the letter after you have read it, as he is a man who may be of great use to me, and whom I would not for the world disoblige. I find the rates are 3 guineas for attending the dissection room injecting for one course and five for two courses, bodies are at present difficult to get there are no whole ones in the dissection room at present, I went there along with G. Reid he introduced me to Cruikshanks I have seen several Edinburgh acquaintances here and some Glasgow ones. In the house where I stay there is a room next mine a much larger one and at the same price which will do finely for you when you come to town. There is a lady and her son here in our house they are the only boarders, he is a clerk to the admiralty but is going to leave the house soon as he thinks it too far off. Direct to me at No. 26 (brass plate) Queens Street Golden square. What makes brass plate necessary is there being two numbers on the door 26 on the brass plate and 21 painted on according as you count from either end of the street.

Present my complts to all the family and Believe me ever to be your dutiful son & affectionate humble servant

"W. HAMILTON"

LONDON Decr 19
1777.

"In the next letter (Dec. 22nd) we are brought closely in touch with the Hunters, and are given a favourable impression of them, particularly of John. The newcomer, being the son of an old friend and companion, received the warmest of welcomes from John Hunter—as this letter shows."

[2] It may help readers if I remind them that in 1777 Dr. William Hunter was 59 years of age, had been established in the Great Windmill-street school for nine years, having first Hewson as his assistant, then William Cruikshank. John Hunter, who then lived in 42, Jermyn-street, was then 41 and had already given three courses of lectures on surgery, his first being delivered in 1773. (See Dr. George C. Peachey's "Memoir of William and John Hunter," 1924.)

LETTER Professor W. Hamilton to his Father: Dated 22nd Decr. 1777:

My Dear Sir

I would have wrote you on Saturday night but went to Dr. Hunters lecture and after the class I delivered my letter, the Dr. asked me and G. Reid who was along with me, to come and eat an oyster with him and we sat till eleven. The Drs class meets from half after one till half after three and on Saturday he had two meetings a night one from six till eight at which I was. This week we meet for tuesday and saturday twice a day he cannot meet at night on the other nights as Mr. J. Hunters lectures in his theatre then.[3] I went to day to fee the Dr., we give the money to Mr. Cruikshanks but he said he would speak to me about that tomorrow when he gave me my ticket. I offered him the dissection fee, but he put off the acceptance of it in the same way. The Dr. is particularly hurried this week as he is affraid his body won't keep, he is on Surgery just now, he explained lithotomy and passing the catheter to day. Bodies are vastly scarce at present some of the men have been taken up and tried but I hope this will be soon over. I waited on Mr. J. Hunter today he said he was vastly happy to see me and enquired very particularly about your health and both he and the Dr. begged their complts to you, he would take no fee from me and said he was happy to have it in his power to be of use to your son, he asked me to dine with him to morrow, and I go to his class to night at seven. The Dr. is an exceedingly good lecturer and vastly plain, he tells a story w grt. humour one or two of which he introduced into his lecture on Saturday. He was vastly chatty with us at supper, G. Reid and he seem to be very intimate he has breakfasted once or twice and dined with him I called at Couts & coy. on Saturday and got the draught paid I called on Bob Hamilton the same day and yesterday he called on me and pressed me to dine with him which I did and drank tea and supped. He boards with a gentleman and sisters who was purser on the Granby before him, he lives No. 73 cannon street in coming home which was about eleven I walked the length of St. Pauls, and then took a coach to which he was so good as convoy me He intends paying Bath a visit for two days in the beginning of January. He is not determined abt going out this year. He expects Mr. and Mrs. Arnot in town every day. He joins me in dutiful compts.

Believe me ever to be My Dear Sir
your dutiful son
"W. HAMILTON."

LONDON Decr. 22
1777.

P.S. I have seen St. Pauls the tower guildhall Bank of England the exchange moorfields the park St. James's queens pallace &c., but I have not been within St. Pauls or the tower yet. I have wrote my mother twice from London.

My Direction is No. 26 (brass plate) Queens Street Golden Square this I send in case you have not got my last.

"In the next letter we have Christmas Day recognised by the sending of 'the compts of the season,' the formula 'A Merry Christmas and a Happy New Year' not being yet stereotyped. The Dr. Black alluded to is no doubt the famous Prof. Joseph Black, friend of both the Hunters and the Hamiltons. 'A Mr. Hume' is Mr. Everard Home, afterwards Sir Everard Home, Br. At this time he was 21 years of age and this is the first notice we have of him as a demonstrator in Dr. William Hunter's school. The spelling gives us the pronunciation of 'Home' in Sir Everard's own circle."

LETTER Professor W. Hamilton to his Father: Dated 25th Decr. 1777:

My Dear Sir

Your letter which I received on tuesday gave me real pleasure it made me happy to find you continued mending and did not need any assistance. I have taken this opportunity of wishing you the complts of the season, and to inform you of my being in very good health. I dined on tuesday with Mr. Hunter, along with a friend of Dr. Black's, his wife is a very pretty woman and a very aggreeable one. Yesterday got my ticket for the Drs. lectures and I feeed Mr and Mr. Cruikshanks for this course. I am affraid I shall not have much for my dissecting fee as bodies are apt to be got and there are several before me. G. Reid has promised to get me one and John the servt who is a very necessary man to be great with, to whom G. Reid has introduced me and spoke for me has promised me the first that comes. The way I am to have it is this, if a body comes Mr. Reid (who has told the pupils he is going out soon to lift one) is to say he got it and of consequence it belongs to him and he is to chuse me for his partner and then we pay the Body to the servt. If a Body be difficult to be got I will see if I can get a head or a leg or an arm or any thing to be doing with. Besides Mr. Cruikshanks there is an assistant in the Dissecting room a Mr. Hume brother in law to Mr. Hunter, Mr. Young introduced me to him, and he seems to be a very good young lad. The Dr. is very near done with surgery and has the nerves still to show and some principles of Midwifery they say his course will not be done before the 20 of next month. Mr. Hunter began yesterday the application of his principles to practice he enter'd on abscesses in his lectures he does not describe any operations except the radical one for Hydrocele, which as it is somewhat odd I shall mention it, he makes an aperture in the cyst lets out the water and thro this opening which he makes pretty large he fills the cavity with pretty thick poultice and lets it stay there till the granulations force it out, in this way he says he has produced several radical cures. I have seen nothing lately worth mentioning. Messrs Reid and Young join me in Compts. to you.

Believe me ever to be My Dear Sir your dutiful son
"W. HAMILTON"

LONDON Decr. 25
1777.

"On New Year's Day young Hamilton wrote both to his mother in Glasgow and his father in Bath. These letters are among the most interesting of the series, revealing the writer both as a dutiful and loving son and one with a real sense of humour. The frank recognition of the employment of 'resurrection men' is interesting. In the letter to his father young Hamilton brings us again in touch with Everard Home."

LETTER Professor W. Hamilton to his Mother: Dated 1st Jany. 1778:

My Dear Mother

I had some days ago the pleasure of your letter which made me very happy as I was wearying much to hear from you. I would have wrote you since Thursday but have been close employed w the Hunters and the Dissecting room, which took up all my time as we had two lectures a day. I wish you the compliments of the season and many happy returns of the new year. I was very happy to find Mr. Wilson had won his plea it was but justice he should. I have no news to write you indeed I would be ashamed to write any after the way the last turned out. I have been through very little of London lately as my forenoon is taken up dissecting, I am now at no loss in the streets tho at first I certainly looked strange for a woman one day passing me looked me in the face and said Oh Sawney is this you. I was so angry at the speech that I could have struck her had she been a man and I had an excellent stick in my hand. What irritated me most was her finding me out to be scotch by my face when I thought I looked very like an englishman. This is the only affront I have met with since I came here indeed the scotch at present are rather respected as otherwise. I am vastly pleased with both Mr. Hunters lectures they are worth coming to London to attend, besides the benefit one derives from dissecting. I expect my father soon here so that he will be home by the first of february at the furthest, and very probably sooner. I would have wrote Mr. Richardson but have been so hurried I have not had time, but will do it this week. G. Reid is pretty well I believe I have not seen him to day. You must excuse this short epistle (scarce worth 8 pence).

Present my dutiful compliments to my aunt and Mr. R. &c.
Believe me ever to be My Dear Mother your dutiful son
"W. HAMILTON"

LONDON Jany. 1st
1778.

LETTER Professor W. Hamilton to his Father: Dated 1st Jany. 1778:

My Dear Sir

I gave me pleasure to find by your last letter that you continued mending and would see me soon. I would have wrote you long before now but have been kept very busy as Dr. Hunter has met twice a day for some time past and on the days he did not Mr. Hunter did, which takes up all the night and in the forenoon I am close employed in the dissecting room. I have got a leg and thigh from the body the Dr. showed the operations upon and I had it injected, I should have done it myself but Mr. Hume said, as it was rather putrid it was not proper for a first attempt as

[3] Dr. Peachey has drawn attention to the fact that John had his brother's theatre for only two courses—1776–77, 1777–78. After then the brothers quarrelled over their shares in the discovery of the true structure of the placenta, and John took a room for his lectures in the Haymarket.

I should be apt to burst the vessels, and he did it and very well injected it is. I have been employed upon it since sunday and I have not got to the knee yet. Bodies are vastly scarce two resurrection men are taken up and all the burying ground is watched so that I am affraid we shall have little dissecting for some time there is nothing but an arm and my leg in the dissecting room at present. I am exceedingly pleased with the Drs. and Mr. H.'s lectures, in Mr. Hunters last one we had his theory of the union of fractured bones which he says is done in three ways. The most common is by the lymph being extravasated and vessels shooting thro it from one bone to the other and making it cartilage, this cartilage is absorbed then, and cells are formed in it fit for the reception of the earth and it becomes bone, this is called joining by first intention. The second way is where the bones lye close together and inflammation comes on, then they unite by the adhesive inflammation. The third way and which is the one probably takes place where the cure of a simple fracture is tedious, the blood thrown out loses its living principle it is therefore an extraneous body and the vessels cannot shoot thro it which prevents the first way and by its being interposed between the ends of the bones it prevents the second way of union, nature then begins to get it absorbed and while this is doing granulations arise from both ends and meet together and in these first a callus and then bone is formed as was in the gelatinous lymph. Mr. Hunters course seems to be an exceedingly good one it principly treats the theory of Surgery and little or nothing of the practice. I have enclosed a letter for Mr. Hamilton I hope you will think it a proper one, you may put a wafer into it and send it to him.
As to St. Georges hospital I might go for a quarter but it is 10 guineas whereas a whole year is only twenty and Mr. Hunter told me if I had any thoughts of being here next winter it would be better to delay it at least till you came to town.
If I can remember right you began pumping on the 5th or 6th of November and you got 200 strokes at first, then after a week or two you had 300.
I shall conclude this epistle with wishing you a happy new year and many returns of it. Present my complts to all the family
Believe me ever to be My Dear Sir your dutiful son
" WILLIAM HAMILTON "

LONDON Jan. 1
1778.

I have enquired where the best bougies are made, you may tell Dr. Ker, it is by one Hodges and if he wants any I shall be happy to serve him and write me how to send them down.

" In the concluding letters of the series, two to his father, and one to his mother in Glasgow, we get in a few sentences glimpses of a busy student life, of old London, and of pleasant domesticities."

LETTER Professor W. Hamilton to his Father: Dated 3rd Jany. 1778:

My Dear Sir
I just now had the pleasure of your letter I own myself much to blame in not writing you, but it was entirely owing to my time being compleately filled up.
I have got all the thigh of my leg dissected I keep on all the muscles and dry them with the vessels I paid half a guinea for it and the injecting. I saw Bob Hamilton lately he known nothing of Mr. and Mrs. Arnots motions and has been expecting them for this some time, he spoke of writing you last sunday, he intended then to see you at Bath next week. I have not heard from Glasgow for some days I expect a letter on monday in return for a letter I wrote my mother. For these three or four days Mr. Cruikshanks has been showing the nerves he does it on just such a preparation as yours and which appears to have been kept for a considerable time.
I hope soon to see you in London and much stronger than when I left you I hope you have had no nephritic complaints, lately. G. Reid and Mr. Young with whom I sup to night beg to be kindly remembered to you. Believe me ever to be your dutiful son and humble servt
" W. HAMILTON "

LONDON Jany. 3
1778.

LETTER Professor W. Hamilton to his Father: Dated 6th Jany. 1778:

My Dear Sir
I this day received your letter and was sorry to find the cold weather pinched you. I heard from my mother on Tuesday last She said then she was going out of town for some days which I fancy has prevented her writing. We had a fire last night opposite to the head of our street we were all a good deal alarmed as at first we thought it was nearer, I had all my cloaths in my trunk in a few minutes and was ready to have carried it to the Dissecting room had it been as bad as we feared it was, it burned w amazing violence and the houses on both sides were saved more from accident than good guiding as the water was at first very scarce and the engines every now and then stopped for the men to drink porter. I was in the crowd from four till near six in the morning. I never saw as few people at a fire in my life. I should have wrote you after its happening lest you might be uneasy about me. I shall wait on Mr. Tait and speak to his nephew who attends Dr. Hunter some day this week as I hope my leg will be done in two days, and then I shall have more time in the forenoon. Present my complts. to the family and Believe me ever to be your dutiful son and humble Servt.
" W. HAMILTON "

LONDON Jan. 6.
1778.

P.S. I hope you got a letter from Dr. Baillie which Dr. Hunter gave me to direct to you about a week ago.
" W. H "

LETTER Professor W. Hamilton to his Mother. Dated 13 Jany. 1778:

My Dear Mother
I this day received the packet by Coll. Abercrombie fo which I am much obliged to you. I was sorry to find by your letter that you was not well I hope long before thi time you have got better of your complaint. I hear yesterday from my father who is vastly well I wrote yo he had had a fit of Nephritis but had free of the stone whic perhaps in some measure caused his other complaints. expect to find him much better than even when I left hi which is just a month to morrow. I heard all about Mis Reids marriage a week ago and wrote it to my father. intend to have a slice of the play to night as I have bee close employed either dissecting or at lecture since thi morning till four when we dine and as I am light and i good spirits frm your packet. My Time is at preser entirely filled up from half ten till half after one and fr that till near four at lecture for the Dr. lectures two hou always and some times more. I dine at four and fr five to six write then I go to the Drs. if there be an eveni lecture till eight and on Mondays Wednesdays and Frida Mr. H. meets at seven for an hour, so that you see I a pretty close kept. My Father is to be in town on Saturd night at which time we shall both write you. Present m dutiful complts to my aunt remember me to Mr. Richards I shall answer his letter soon. Believe me ever to be
My Dear Mother your dutif
son and humble Serva
" W. HAMILTON "

LONDON Jany. 13
1778.

" The rest of the story can be found elsewhe and much of it is in the 'Dictionary of Natio Biography.' We do know from other sourc particularly from letters written by Dr. Willia Hunter in 1779–80, that William Hamilton h a most successful period in London. He beca an inmate of Dr. Hunter's house, then his assista and subsequently was given charge of the museu Even when at Windsor Castle attending on Queen, William Hunter, in a moment of leisu wrote to the ageing professor of anatomy Glasgow in the warmest terms of praise in fav of his son. In 1781, came the father's final illne his son, William, left the Hunters and returned Glasgow to succour his father and to become assistant and then successor. Then followed untimely death, in 1790, at the age of 32. A account of his life was published in the *Transacti* of the Royal Society of Edinburgh for 1792, and brightest part of that life were those two years spent in London with the Hunters.

" Three letters which John Hunter wrote to about patients are not reprinted here. The fact t Dr. William Hamilton preserved them shows value he attached to them and to their writer. letters speak for themselves—and they also speak behalf of William Hamilton. The one point one notes in these letters—as in the surgical lit ture of their period—is the attention and study g to hydrocele, an ailment which occupies so in

scuous a place in current medical literature. Will appendicitis be relegated to a similar position in another century and a half?"

JOHN HUNTER'S EXPERIMENTS:

EVIDENCE OF AN EYE-WITNESS.

In her treasure-trove of correspondence Dr. Louisa Hamilton has discovered yet another letter which gives us quite new information regarding the point which John Hunter had reached in his discoveries in the year 1771—the year in which he and Jane Home were married. John Hunter was then in his forty-fourth year and had been a surgeon to St. George's Hospital for three years. The letter was written by Dr. W. Irvine in the summer of 1771 to his old friend Prof. Thomas Hamilton—father of the young man whose letters are reproduced above. Dr. W. Irvine and Dr. Thomas Hamilton had both studied under Dr. William Hunter; Dr. Peachey has drawn attention to the fact that Dr. W. Irvine was also used as a witness when Monro secundus was accused by Dr. William Hunter of plagiarism.

LETTER Dr. W. Irvine in London to Prof. Thomas Hamilton, University of Glasgow.

LONDON, June 17, 1771.

Dear Sir,

You did not, I dare say, imagine to see my name at the foot of a letter of this date from London, but I have been detained, longer than I expected, about Dumfries and in Yorkshire, and have been so agreably employed here that I could not think of leaving it sooner. I have spent most of my time for the fortnight past with John Hunter, from whom I have received a great deal of what is new to me and which, tho' it may not be so much to you, cannot however be disagreable.

John Hunter has observed that if a wound be made into any cavity, if the edges are applied so as to be in close contact, they cohere, as on other occasions, by the first intention without suppuration; but if instead of applying the edges close to each other anything is put in to prevent their touching each other, an inflammation and suppuration is produced, which extends itself over the whole cavity to which the incision is made, how large soever the cavity may be. This he has found to be the case by many experiments and he thinks it may be applied to account for several things in surgery and to improve others.[4] Thus in the hydrocele, when a wound is made in the scrotum thro' the tunica vaginalis, the water flows out, the scrotum collapses, the wound heals up and the water collects again. But if the wound in the scrotum, however small, is prevented from healing by any means such as a caustic, a seton, lint, sponge-tent, etc, destroying the tunica vaginalis, an inflammation attended with suppuration is produced, which extends itself over the whole surface of the testis and tunica vaginalis. Granulations spring from the testis, an adhesion between that and the scrotum is produced and the disorder is cured. He founds his method of operating on the hydrocele on this idea which he has performed above ten times, with all the satisfaction he could desire. The first time he performed it was on a Nobleman who went everyday after the operation to the house of Peers till he was cured. He makes a small wound with a lancet in the most dependent part of the scrotum, so as to be free of the testis—of the size of a common bleeding. As little of the water is allowed to escape as possible. A sponge-tent is put into the wound so as to penetrate through the whole solid part of the bag. After, a proper bandage remains. The night after the operation, or next day, an inflammation which ends in suppuration—attended with swelling of the scrotum and pain in the spermatic cord come on, and the tent comes out of itself The water flows all out; pus flows from the wound. The parts are poulticed and all is well in three weeks. In some cases there was a considerable pain in the back, but scarce any fever. He has observed an inflammation and suppuration similar to this after tapping both the abdomen and thorax, when the wound did not heal up, and that he has dissected subjects who from this had a suppuration over the whole surface of the viscera in the abdomen or the thorax.

He has made several curious experiments on the blood, from which it appears to have something of a vital principle in it, so that all parts where it stagnates become vascular, which they would not otherwise do. This is confirmed by the following experiment. He made two ligatures on the jugular vein of a dog at a little distance from each other, so that a quantity of blood was contained betwixt them. The external wound was dressed and healed, and the dog, after living several months, was killed and upon examining the jugular vein a number of fine blood vessels were found in the cavity which contained the blood, arising from the two ligatures and running in various directions, into the cavity of the vein. The vein betwixt the ligatures was as large as at first, but no blood was found in it, the whole was a congeries of vessels. No vessels are ever found in the vein when it is emptied of its blood before the ligatures are made.[5]

Mr. Hunter has dissected many subjects upon whom the operation for aneurism had been performed.[6] No vessels were ever found in the artery betwixt the ligatures, though the lateral branches were greatly enlarged. From this[7] he accounts for the formation of Callous in a broken bone. A quantity of blood, thrown out on the two surfaces, becomes vascular. That this vital principle of the blood is retained after its separation from the body and sometimes after coagulation. This accounts for many surprising things which are every day being performed here, either by himself, or by others, and which if they came from any other body but one of his credit, could not be believed and which you yourself may accuse me of credulity for believing but I assure you I have seen almost all of them myself.

The pulling a diseased tooth from the head of a person and putting a fresh tooth from another in its place and this growing firm as the other teeth I have seen, and I am assured by John Hunter that these engrafted teeth get vessels and nerves and that this happens when a sheep's tooth has been grafted into a human head.[8]

The cutting of spurs from the heel of a cock and making them grow in his head, J. Hunter has often performed and has such cocks at present. Nay more, he has many hens just now into whose abdomen, when young, he has put the testis of a cock just separated from his body and this testis has got blood vessels and nerves from the part of the abdomen or viscera to which it is applied; has increased in size, yields a white liquor when it is cut into, but has not, as he had imagined, impregnated their ova nor altered their natural disposition.[9]

He is tomorrow to perform an operation of this kind before several gentleman. He has procured a couple of Jack Apes. Into the forehead of the one he is to graft the horn of a calf, and into the other the horn of a young deer and he proposes, as Gavin Pettigrew[10] has long complained of want of money, to send them to him and doubt not that by shewing them up and down the country he will make an immense fortune. The success of these operations depends on there being little time lost betwixt the separation of the part from one animal to the other, tho' it succeeds after being separated longer than can well be imagined.

Not to bore you I will mention one other thing out of a great number—Viz. male animals of the more imperfect kinds have small testes in the Winter and a very large in Breeding time. Mr. Hunter has preserved six male sparrows,[11] killed betwixt December and the middle of

[4] It is of interest to note that the problems which John Hunter—a Scotsman—was investigating in London during the "sixties" of the eighteenth century were solved by Lister—an Englishman—in Glasgow during the "sixties" of the nineteenth century.

[5] From this account we see that John Hunter was still searching for proofs of his belief that the blood is a living tissue. This belief began in 1756 as he watched the formation of blood islands in the developing chick. So far as we know Dr. Irvine's account is the first information we have of these ingenious experiments by Hunter on veins.

[6] Hunter's first operation on popliteal aneurysm, by tying the femoral artery, was done in 1785, 14 years after this letter was written.

[7] "This" we take to refer to the organisation of the clot in the ligatured vein.

[8] Hunter grafted human incisors in the combs of cocks. One of his specimens is preserved in the museum of the R.C.S. The union is effected by a vascular process which has grown from the substance of the comb into the open canal of the root of the incisor.

[9] The sole record of these experiments is a brief paragraph in John Hunter's lecture (vol. i., p. 391, Palmer's Life of Hunter, 1837). This passage runs: "Here is the testicle of a cock, separated from that animal and put through a wound made for that purpose, into the belly of a hen, which mode of turning hens into cocks is much such an improvement for its utility as that of Dean Swift when he proposed to obtain a breed of sheep without wool." Did Hunter ultimately find that the disposition of these engrafted hens did become changed? The extract from his lectures (1792) seems to suggest he did. Berthold, of Göttingen (1849) is usually supposed to have been the first to transplant with success the genital glands of fowls.

[10] This I take to be John Hunter's particular friend mentioned in letters written by him in 1761, when in Belleisle to his brother William in London. In these letters Pettigrew is asked to wait on Dr. William Hunter and obtain from him instructions regarding certain of John's private affairs. Apparently the experiments failed and Gavin Pettigrew remained poor.

[11] These specimens are in the Museum, R.C.S., and are still in a perfect state of preservation.

April. The one killed in December has testes not bigger than a small pin's head, the rest are gradually larger, the testes of the last, killed in April, are as large each as the top of your little finger. Same in frogs; remarkable in the skate which in Winter is not half-an-ounce and in summer near half-a-pound.

I have explained to Mr Hunter, in the best manner I could, your ideas about midwifery and have the satisfaction to inform you that he is entirely of your opinion, particularly about the menses and the decidua vera. He begs leave to add to your stock of facts some which he has found by his own experiments. A cow, free of her milk, after being in case, kept from the bull, has a show of blood every month after that, and frequently external. He has observed the same in deer, bitches, monkeys, etc.

I have mentioned to Mr Hunter your wants in the Waxline and he proposes to get them all for you by the time I come back to Britain [12] Those I mentioned are a placenta, the ', , , another fœtus, twins, a glass uterine speculum(?). If I have neglected anything you mentioned to me I beg you would let me know of it. I have only seen Dr. Hunter once since I came here. I am to be with him tomorrow by ten to look over his Museum along with the Portuguese ambassador. It is a fine room and an excellent house.[13] The pictures in his back parlour cost him within a trifle of a thousand pounds at Stranze's sale. He tells me that in all his practice for these ten years he never used any instrument whatever in delivery; that he never attempts to deliver the placenta but allows it always to come away of itself, and never minds tho' the uterus close on it, for it will open again and be delivered, tho' he has seen it remain sometimes a day or two. This is always attended with some secondary pains.

John Hunter was very busy last day in making up a runaway private marriage between the son of a nobleman and the daughter of an Earl's brother. The whole is a secret yet. It is much against the will of the father of the young man, who knows, as yet, nothing of it. John [14] sent them to Scotland last Saturday night and as they had no money he had the dexterity to get hold of the money of the father of the young man and gave it to his son for a purpose of all others the most disagreable to him. It will make a great noise tomorrow or next day and you will soon see their names in the newspapers.

I thought I should be able to send you a book of Hunter's, the property of which he sold for 200 guineas and which, tho' quite printed and finished is not yet published. It is in quarto, an essay on the teeth about 150 pages in length, with about 16 copper plates but I could not persuade the bookseller.

I have wrote too long a letter but I thought many of the things would be agreable to you in consequence of which they were the more so to me. I have several others equally curious which you shall hear of again. I shall leave London tomorrow night and shall be in Paris if the wind serves, before you read this letter. I wish I could hear of you soon. A letter addressed to me to be left at the Scots College would come safe, as Pater Cummin is in Paris and desires his letters to be addressed in that manner. My best compts to Mrs. Hamilton.

I am yours

W. IRVINE.

Dr. Irvine's letter gives us a better picture of John Hunter at the height of his genius and energy than any letter we have as yet possessed, not even excepting the Jenner letters. There could not have come a more telling witness on behalf of the man whose bicentenary is being celebrated, and we owe to Dr. Louisa Hamilton a great debt for its publication.

[12] Dr. Irvine was on his way to Paris.

[13] This refers to Dr. William Hunter's House and School on Great Windmill-street. The building may be still seen on the left as one enters Shaftesbury-avenue from Piccadilly-circus. It is now used as the dressing rooms and stage of the Lyric Theatre (Peachey). William Hunter erected this building in 1768.

[14] John Hunter apparently did not give Dr. Irvine a hint of his own impending marriage. He and Anne Home were married in St. James, Piccadilly, Sunday morning, July 22nd, 1771, less than five weeks after Dr. Irvine's letter was written. The incidents related in this letter do not indicate any lack of money on John's part; yet it is said he sold the copyright of his work on the Teeth to pay the outlay involved by matrimony.

LONDON HOSPITAL SATURDAY FUND.—At a meeting of the board of delegates it was stated that there was an increase of £4665 over the previous total, and that £73,726 was available for disposal. St. Thomas's Hospital has been given a grant of £2425, the London Hospital £2185, University College Hospital £1995, and St. George's £1975.

THE THOMAS VICARY LECTURE

ON

THE HOMES OF THE HUNTERS.

BY G. C. PEACHEY.

IN his examination of Scottish intellect Buckle the historian of civilisation, after reviewing the philosophical works of Francis Hutcheson, Adam Smith, David Hume, and Thomas Reid, and the scientific labours of Joseph Black in chemistry, of James Hutton in geology, of James Watt in mechanics and of William Cullen in medicine sums up by saying: "I have now only one more name to add to this splendid catalogue of the great Scotsmen of the eighteenth century, but it is the name of a man who for comprehensive and original genius comes immediately after Adam Smith, and must be placed far above any other philosopher who Scotland has produced; I mean, of course, John Hunter." Buckle claims for Adam Smith the greater clearness and flexibility of thought. It may be so. But at the same time he places Hunter among the great masters of organic science in the same rank as Aristotle, Harvey and Bichat. Among the scientific men of outstanding intellect selected by Francis Galton to illustrate his theory of the transmission of hereditary ability may be found in the first degree the name of John Hunter, and on a lower plane those of his brother William, his nephew, Matthew Baillie, and his niece Joanna Baillie. When Lavater saw John Hunter's portrait he exclaimed: "That man is a thinker," and it must be recognised that the really great men are not the great experimenters, the great observers, the great readers nor the great scholars, but the great thinkers. It is the progress of ideas which ultimately determines the progress of the world; John Hunter not only thought himself but he set men thinking.

This week we are celebrating the bicentenary of John Hunter's birth, and I wish to address you not upon the magnificent museum on which he spent almost the whole of his earnings, nor upon his perseverance in collecting the facts on which he based his original conceptions of disease; nor shall I attempt to explain the discoveries he made, and their bearing upon modern science. But I ask you to accompany me to the various dwellings of his brother and himself and to follow their footsteps round the London of the eighteenth century. It was the London of Gay and Hogarth, of Fielding and Smollett, of Johnson and Goldsmith.

The scene opens at Long Calderwood in the county of Lanark, where during the night of Feb. 13th, 1728, John Hunter was born, the tenth child of his parents, his father being then well on in years. (Fig. 1.) We know that John, his mother's darling, was a spoiled child, that he was wayward and idle in his early youth, and that he neglected his studies at the Grammar School in favour of country amusements. The three eldest children had already died—probably of tuberculosis—three more were to fall victims to the same disease, and four only of the family of ten come into our story. They were James, William, Dorothea, later the mother of Matthew Baillie, and last of all John Hunter. That the home life at Long Calderwood was brightened with the warmth of brotherly and sisterly affection is evidenced in the correspondence which passed between them: to each other they were Jamie, and Willie and Jockie, and Nannie and Tibbie.

After their father's death, though James was the eldest surviving son and had succeeded to the small estate, William Hunter became the dominant figure, and acting as parent and teacher to each of his brothers, and his nephew and heir Matthew Baillie, he and he alone was the architect of their success in life. It was William who bore the burden and heat of the day, and in the intensity of our admiration for the genius of John Hunter it is right that William should receive his meed of honour. James the elder

on was already studying for the law, in Edinburgh, nd William, designed by his father for the ministry, matriculated at Glasgow, and studied theology there or five years. But by that time his religious opinions ad changed and meeting with the great William ullen he abandoned the Church, and for three years ractised surgery with Cullen at Hamilton. These, e afterwards said, were the happiest years of his fe, and he never spoke of Cullen without gratitude or his tuition and guidance. But William Hunter lready had larger schemes and higher ambitions, nd with the object of acquiring knowledge it was greed between himself and Cullen that he should isit Edinburgh and London before settling down to ountry practice. The first part of the programme as completed at Edinburgh, and in the winter of 740 he made his way to London by sea, and after a erilous voyage found himself under William Smellie's oof in Pall Mall.

This was William Hunter's first home in London. he house stood in one of the courts within the great ates of Carlton House, at that time in the possession f Frederick, Prince of Wales, and later the residence f the Regent. The exact position of Carlton House as the space between the present Athenæum and Jnited Services Clubs, facing Waterloo-place. It was aken down with the adjoining property in 1826 and he only remaining vestiges are its columns which ow front the National Gallery. William Hunter as particularly fortunate in his teacher, for Smellie as a remarkable man. Dr. Herbert Spencer, in his History of British Midwifery," calls him the master f British midwifery, and describes him as the greatest f British obstetricians. Without powerful friends to elp him, or the advantages of a hospital clinic, but y attending and teaching in the homes of the poor, nd by sheer devotion to his art, Smellie raised him-elf to the foremost position in his profession. But n 1740 he had just arrived in London; he was only humble apothecary and accoucheur, and had not s yet started the lectures which, though they excited

FIG. 1.

Long Calderwood, where William and John Hunter were born.

he derision of his critics, brought fame to him, and credit to his pupils.

If I read William Hunter's mind aright, he realised quickly, while he attended the courses of Frank Nicholls in anatomy and Dr. Desaguliers on natural philosophy, that he had gleaned in ten months what he could from Smellie's private tuition in midwifery and that the time had come for him to take another step forward. But there is little doubt that the instruction he had received from Smellie during those ten months laid the foundation of much of his subse-

FIG. 2.

William Hunter's Residence and School of Anatomy in Great Windmill-street, W.

quent success, while the somewhat awkward and uncouth manners of his teacher—for Smellie's hands were said to be large enough to stretch boots in Cranbourne-alley—taught him a useful lesson, by suggesting to him the cultivation of the more courtly bearing which subsequently procured for him his appointment to Queen Charlotte. Armed with an introduction to Dr. James Douglas he made his way to Red Lion-square, where he was kindly received and invited to become Douglas's anatomical assistant and tutor to his son. With Cullen's generous acquiescence the Hamilton project was abandoned, and William Hunter took up his residence in Douglas's house. London had become his darling.

James Douglas was then nearing the end of a career which had brought him distinction as an anatomist, an obstetrician, and a bibliophile. He had gathered round him a superb collection of the editions of Horace, of which he issued a printed catalogue; he had described and demonstrated Douglas's pouch; Haller eulogised him: Pope has immortalised him.

> "There all the learned shall at the labour stand,
> And Douglas lend his soft obstetric hand."

Sojourn in Smellie's house had turned William Hunter's thoughts to midwifery and the importance of what Lord Chesterfield called "the Graces" was further brought home to him by his association with Douglas. Short as this was destined to be, the effect it produced upon his character was three-fold—it gave him a love of books, a zeal for anatomy, and a choice of obstetrics as a means of future livelihood. It was with Douglas, and after his

death with his family, that William Hunter and his brother James who, abandoning the law decided to follow medicine as a profession and to join his brother in London were to find a temporary home. That winter he entered St. George's Hospital as a pupil.

The voluntary subscription hospital movement was in its youth; St. George's itself was then only seven years old. The parent institution at Westminster had opened its doors in 1719, previous to which the only general hospitals in London—indeed in the whole of England—were St. Bartholomew's in Smithfield and St. Thomas's in Southwark. The westward march of the town was extending to the fields on which the May Fair had previously been held; extensive building operations were in progress, and there was need for further hospital service and accommodation. The House of Lord Lanesborough, then recently deceased, was ideally situated, standing as it did in the field facing Hyde Park, and over its front door his Lordship's sentiments:

> "It is my delight to be
> Both in town and Country."

And in the country it actually was, for the western turnpike gate of London was then at Clarges-street, though 50 years before, when Burlington House was built, its noble owner, when asked why he had erected his home so far out of town, replied that he was determined to have no buildings beyond him. So rapid had been the progress westward. From the windows of the hospital facing north little was visible but open country; just inside the park palings might have been seen the mound erected by Oliver Cromwell for the defence of London—on which the so-called Achilles statue now stands, and on the right, across Tyburn-lane, another known as Oliver's Mount from which Mount-street gets its name. Looking towards what is now Albert Gate might have been observed a small domed-brick building. It was known as the St. James Conduit House, and may be seen within the park railings opposite the Alexandra Hotel.

In 1736 the governors of the hospital purchased the freehold for £500, and a picture by Richard Wilson shows the hospital as it was when William Hunter entered it as a surgical pupil in 1741. It remained practically unaltered during the whole of that century while John Hunter was the chief ornament upon its staff, until, in 1824, it was rebuilt, when its front was turned towards the east. On its western side is to be seen "The Cottage," still so-called, which was John Hunter's home for a while, and continues to furnish quarters for the resident staff. The humble dwelling of the dairyman who supplied milk for the patients is seen in the picture to stand on the roadside, and the turret of Chelsea Hospital may be discovered in the distance. For Grosvenor-place was then a country lane, leading to Westminster and the Five Fields, now Belgravia.

Scarcely had the winter session opened in October, 1741, when the news came to William Hunter of his father's death, to be followed six months later by that of James Douglas, his patron and employer. It must have been a heavy blow. He had burned his boats in Scotland, his elder brother James had forsaken the law and joined him in London; the burden of responsibility for the whole family was upon him. "'Tis in vain," he wrote to his mother, "to say that neither Jamie or I is the loser by Dr. Douglas's death, but we are in a very good way." But he had courage and confidence in himself. Already he had formulated schemes for the future and had determined to become a teacher of anatomy himself, when he should have acquired sufficient knowledge and such a collection of preparations—then necessary for teaching—as would ensure him success. That winter William Hunter visited Paris, and attended a course of lectures on anatomy, but during his absence his brother James, broken in health by his assiduous attendance in the dissecting room, had returned to his Scottish home, to die of hæmoptysis.

Of the family of ten children four only now r mained, and the expectation of life of the survivo was not promising. Again William Hunter foun himself alone in London; he had succeeded on h elder brother's death to the small estate, but h mother, his two sisters, and his brother John we entirely dependent upon him. He was in his twenty eighth year. But events were moving forwar towards the launching of his long-contemplate scheme; the dissolution of the United Company Barbers and Surgeons and the abrogation of th bylaw prohibiting the dissection of the human bod outside their hall afforded him a favourable oppo tunity, and in October, 1746, he announced in th newspapers the commencement of his first course lectures on anatomy. There were many others in th field before him; it was to be an uphill journey, b never was perseverance better personified than i the two brothers, William and John Hunter. Th chosen venue was the Little Piazza, Covent Garde the selection of which by him and other teachers w due to its central position. Covent Garden, once fashionable quarter, was no longer in favour wit society which was now flocking to the squares ar Mayfair, and the purlieus of Old Drury and the ne Covent Garden Theatre were given over to anatomist actors, "starving poets," and men of letters. Ar now William's only surviving brother, John, tired an idle country life, and hearing much of William success, wrote offering to become his assistant, or that proposal were not accepted expressing a desi to go into the Army. The offer was well receive and John set off on horseback for London. He w in his twenty-first year. On arrival he doubtle joined his brother, who was then residing Mrs. Douglas's house in Hatton-garden, and for t next 12 months this was probably John Hunte home. During that period he was initiated into t art of dissecting and proved himself so efficient th he was soon able to instruct his brother's pupils.

In the summer he went to Chelsea Hospital learn surgery at the feet of Cheselden, the gre surgeon of the time, returning in the winter to t dissecting room in Covent Garden, and when Cheseld succumbed to a stroke of paralysis John Hunt continued his studies as a surgical pupil at St. Barth lomew's Hospital. But William Hunter's priva practice was growing with his reputation. For a fe months he deputised as a surgeon man-midwife at t Middlesex Hospital, then recently established serve the district of St. Giles, until on the openi of the Hospital for Lying-in-Women in Brownlo street, Holborn, in 1749, he was elected to its sta From his subsequent movements it appears to r that William Hunter had grasped the importance the principle that, for the safety of the women attended, his practice should not be conducted fr premises which served at the same time for dissectin and we find that he immediately took over a lar house in the Great Piazza, Covent Garden, whi henceforth became the residence of himself, his broth John, and their pupils. At the same time he retain the apartments in the Little Piazza for anatomi purposes. This was in the autumn of 1749, almo one hundred years before Semelweiss, in 1847, was l to attribute puerperal fever to the carriage of sep from the attendant to the patients.

In 1753, at the age of 25, while still in his pupilag and after only five years of study, we find that Jo Hunter was elected a master of anatomy at Surgeon Hall in company with Percivall Pott, over the hea of many of his seniors. No higher tribute could ha been paid to his knowledge of anatomy. He h evidently made up his mind to follow surgery as l profession. In 1754 he entered as a surgical pu at St. George's Hospital, and again in 1756 for second course. The intervening summer is account for by his entry as a gentleman commoner St. Mary's Hall, Oxford. That he did not go there his own inclination is certain from his later rema "They wanted to make an old woman of me or th I should stuff Latin and Greek at the Universit

ut these schemes I cracked like so many vermin s they came before me." The simile was apt if npolished. In after years we find him writing in esponse to his irritating and venomous critic :— Jesse Foot accuses me of not understanding the ead languages, but I could teach him that on the ead body which he never knew in any language ead or living." Foot's detraction was probably ue—there is generally a strand of truth in the bric of his hatred—but John Hunter was certainly ght : as regards anatomical knowledge comparison etween them would be fatuous.

John Hunter's choice of St. George's as his finishing chool was of good purpose. At the chartered hospitals sailed for Belleisle, and there and in Portugal he served for a little more than two years.

Six letters from him to his brother have been preserved, and, characteristic of his temperament as they are, I am tempted to quote extracts from them. He was a bad sailor. " The sea plays the devil with me," he wrote, explaining his preference for land service ; which by the way, at the same time, offered chances of better pay. Again he says, " Thank God I have succeeded in everything I have attempted, but my practice in gunshot wounds has been in a great measure different from all others, so that I have had the eyes of all the surgeons upon me, both on account of my supposed knowledge and method of treatment.

FIG. 3.

Earl's Court House : John Hunter's residence from 1765 to 1793.

ve years of apprenticeship to one of the surgeons as then necessary—it remained so till within living emory—whereas at St. George's there were no estrictions : the appointments were open, subject votes and influence alone. Whatever the evils of he system, and they were many, without it surgery ould not have had its John Hunter. In 1756 he as appointed resident house surgeon at St. George's, stepping-stone to the staff, but he only retained the ffice for five months, anxious as he was to return to he dissecting room and complete the researches upon hich he was engaged. The same year William Hunter oved to Jermyn-street, then a favourite medical uarter, gave up the apartment in the Little Piazza, nd henceforth the house in the Great Piazza served s a residence for John and the pupils, and as the chool of anatomy. In that house John Hunter ntinued his anatomical researches until, in the mmer, he contracted pneumonia. He had comleted 11 years in the dissecting room, and it was vident that he could go on no longer. With the mily history before him, the warning was too efinite to be passed over. Immediate and prolonged hange of occupation was necessary. The period of nvalescence was spent in the country, probably at arl's Court, then a hamlet two miles from London, aried by occasional visits to town, until having pplied for and obtained a commission as a surgeon n the staff of the Army, in the spring of 1761 he My fellow creatures of the hospital are a damned disagreeable set." John Hunter was not altogether an easy person to get on with ; neither he nor his brother could endure opposition ; they quarrelled with others, and eventually quarrelled between themselves.

Before he left England John Hunter had become a subscriber to St. George's, and there at a board meeting we first meet with him after his return. There is little doubt I think that he was then living in lodgings in Russell-street, Covent Garden, in the house of William Jones, the druggist, and that apart from his own dissections and researches he filled in his time by entering into some sort of professional association with Spence, the dentist, in Soho-square. But two years after his return to England he purchased the lease of three pieces of ground at Earl's Court, on which he proceeded to build a residence, and nine months later he became the occupier of a house in Golden-square.

Now we return to William Hunter. Long before his attendance in 1762 upon Queen Charlotte at the birth of a son, afterwards George IV., William Hunter having acquired a competency for himself and finding that his wealth continued to accumulate—he had already spent from £3000 to £4000 on his library—resolved to give up teaching anatomy. He vacated the Covent Garden premises, but yielding to the pressing calls of his pupils to continue his lectures,

in pursuance of a design he had in contemplation, he presented a memorial to Lord Bute, praying for a grant of land from the Crown on which he proposed to lay out £7000 in building a museum of anatomy and to present it to the nation. After long delay the offer failed of acceptance. Had it materialised the name of Scotland Yard, the chosen site, would have been associated in the public mind with the investigation of disease instead of crime. He took temporary premises in Litchfield-street, Soho, where his lectures were carried on until, foiled in his original design, he purchased a house in Great Windmill-street and commenced to build a theatre for himself. There from 1768 to his death in 1783 William Hunter, with a succession of distinguished assistants, Hewson, Cruikshank, and Sheldon, continued his courses of anatomy; after his decease the property passed to his nephew and heir, Matthew Baillie, until, in 1831, its doors were finally closed.

Of all the homes of William Hunter a part of this alone remains. The Little Piazza has long disappeared, the house in the Great Piazza was demolished and rebuilt about 50 years ago, the site of his Jermyn-street residence is now occupied by Prince's Hotel, and the Litchfield-street premises have been swallowed up by changing London. The red wall in Great Windmill-street, now the back of the Lyric Theatre, is the actual frontage of the old house. The front portico has gone, the area remains, and behind the railings may be seen the basement windows. Through the side entrance to the north the actors and actresses now pass to their dressing-rooms above, and a flight of steps is seen down which many a resurrectionist must have staggered under his ghastly burden. A few days ago I stood upon the stage of the theatre which is sunk below the level of the street, and which formed the actual floor of William Hunter's School of Anatomy.

When William Hunter vacated Jermyn-street in 1768 he handed over the remainder of the lease to his brother, and John Hunter with William's support was elected surgeon to St. George's Hospital. "When I solicited to be appointed one of the surgeons," he wrote, "it was not with a view to augment my income, either immediately by the profits of the hospital, or in a secondary way by increasing my practice, but to acquire opportunities of extending my knowledge that I might be more useful to mankind, not only by improving my private practice, but if I should be enabled to make discoveries even in the art itself." So did he write in 1793 in a letter to the governors. The appointment yielded him what he desired, attendance upon the living and examination of the dead; and, moreover, it enabled him to take

FIG. 4.

John Hunter's wife, *née* Anne Home. From the original by Masquerier.

pupils, one of the earliest and certainly the greatest of whom was Edward Jenner.

John Hunter's association with Jenner must have been a constant delight to each of them, and though we know little or nothing of the incidents of the two years of their companionship in Jermyn-street, a series of letters remains, wherein it is possible to trace the objects of Hunter's pursuits, the progress of many of his experiments and researches, in some measure the evolution of his thoughts and ideas. These letters bear testimony to the friendship which existed between them. The exact date of the termination of Jenner's residence in Jermyn-street is conjectural; he may or may not have been there in July, 1771, when one Saturday evening, John Hunter wrote a letter to William: "Dear Brother, — To-morrow morning at eight o'clock and at St. James Church enter into the Holy State of Matrimony. As that is a ceremony which you are not particularly fond of, I will not make a point of having your company there. I propose going out of Town for a few days when I come to Town I shall call upon you. Married or not married, ever yours, John Hunter. Sunday morning at eight o'clock! The honeymoon was probably spent at Earl's Court, and the expenses of the wedding are said to have been provided by the sale of his tooth upon the Teeth. (Fig. 3.)

From his marriage onward he made good use of Earl's Court. "For two or three months in each year," he wrote in 1775, "I am pretty much in the country, making experiments upon animals and vegetables"; sleeping there, coming to town in the morning, and returning to dinner. Around the house at Earl's Court, until its demolition in 1886, there lingered a halo of romance, the romance of John Hunter's otherwise turbulent life. It was there his honeymoon was spent, it was thither he fled from the town to his family, his fields, his trees, his ponds, and his animals. (Fig. 4.) Mrs. Hunter's apartments were upstairs, set apart from the lower regions where his study looked eastwards on the meadows beyond, so that he could keep a watchful eye on the "Den" where the wild beasts were kept. Round the house ran a cloister in which he kept the smaller animals used for his experiments, the entrance to which was by a subterranean passage and through which, in Frank Buckland's words, "Master John could wheel a tiny sized cart or truck and drag into his den anything from a Giant's body to a good-sized whale." This burrow opened not far from the stables, and Hunter could easily whip anything into the stable yard, down the burrow and into the area without Mrs. Hunter knowing anything about it. "I'll be bound," added Buckland,

remembering I am sure his own very similar domestic position, "I'll be bound to say, she used occasionally to lead him a life, and kick up a row if any preparation with an extra effluvium about it was left on the dissecting table"; and then calling upon his imagination Buckland pictures "The great John with his bright intelligent eyes, expressive eyebrows, and white hair curled behind, with his hands in his pockets, smiling his satirical smile" and saying, in allusion to Buckland's friendly offices, "So, Master Frank, there you are again; you found my remains in the vaults of St. Martin-in-the-Fields, and got me buried in Westminster Abbey, and now I find you actually in my house investigating my private skeleton-making copper?" In this copper was boiled the body of the giant O'Brien, whose skeleton is now in this museum. It is said that O'Brien had expressed an earnest desire to be buried at sea, but John Hunter had other intentions. At great expense the body was removed by night in a hackney coach, and having been carried through several streets, was transferred to Hunter's carriage and conveyed to Earl's Court. There the gruesome work was completed in the copper. It is said to have cost him £500.

All John Hunter's animals, like their master, were devoted to science; his pigs were fed with madder till their bones were red; the spurs of his cocks were transplanted into their combs; his ducks were fed on sprats till they tasted of fish; his pigeons, turkeys, geese, eagles, owls, hawks, and his ostrich were used for all sorts of experiments. Wolves, jackals, and dogs; donkeys, mules, zebras, horses, and cattle were all mated where possible, and produced curious hybrids. In the middle of the field at the back was a pond, mentioned in the original conveyance of the property as the "Great Hole," in which John Hunter cultivated pearls from mussels, and where he kept his fish, frogs, leeches, and eels. In one corner was a mound, in the western face of which was a passage leading to three vaults, where he kept the dangerous animals.

Tales are told of his perilous encounter with a young bull, in wrestling with which he was thrown down, and of an occasion on which he found himself in a melee between two leopards, which had got loose, and several dogs. Unarmed he instantly laid hold of both the leopards, which fortunately submitted to be led back to the den and secured. And all around the grounds were the trees, which were stripped of their bark and bored with holes, in which he placed his thermometers, in order to carry out his experimental researches into the heat of vegetables.

The letters to Jenner who had settled in country practice at Berkeley, whence in the after years he was to issue his immortal "Inquiry into the Variolæ Vaccinæ," are full of allusions to Hunter's experiments. He keeps on asking for information as to the habits of the cuckoo and the breeding of toads. "If you collect eggs you should also collect the nests: I want a crow's nest, also a magpie's in the branches where they are built. I want a nest with the cuckoo's eggs in it, also one with a young cuckoo, also an old cuckoo. I hear you say there is no end of your wants." Again, "I thank you for your experiment on the hedgehog, try its heat and let me know the result. You do not mention a word about bats: Have you got the bones yet of a large porpoise? Is ever the salmon spawn seen after she has parted with it? I will take any specimens of fossils you may send me, or indeed anything else. What do you think of examining eels? Their sexes have not yet been found out, nor their mode of propagation." In the spring of 1778 he was asking for more hedgehogs: "All that you sent me have died, so that I am hedgehog-less." And then in one letter, after acknowledging the receipt of a consignment of various objects, he adds: "I was told the other day you was married and to a young lady, with considerable fortune. I hope it is true. What has become of your paper on Lead in Cider?" Jenner's reply is explained by Hunter's subsequent letter: "I was at a loss to account for your silence, and I was sorry at the cause. I was glad when I heard you was married to a woman of fortune; but let her go, never mind her. I shall employ you with hedgehogs."

FIG. 5.

Lady Campbell, John Hunter's Daughter. By Masquerier or Zoffany.

I might continue almost indefinitely, for there is nothing that presents to us so truly John Hunter in his habit as he lived as these letters to Jenner.

At least during the summer months he used Earl's Court as a residence. When in London from six in the morning, or even earlier, until nine he was in the dissecting room; after breakfast he saw patients at his house, before going his round of visits. He dined at four, after which he slept for about an hour, and when not lecturing he dictated to Bell, his amanuensis, till one or two in the morning, leaving only four hours for sleep. The story goes that his friend Maxwell Garthshore dropping in one morning and finding him very busy remarked, "Ah, John, you are always at work." "I am," was the reply, "and when I am dead you will not soon meet with another John Hunter."

In 1770 he began to lecture privately to his pupils, and in 1775 the first public announcement of his lectures on the Principles and Practice of Surgery appeared in the newspapers. The two following years they were delivered at his brother's anatomical theatre in Great Windmill-street, but in 1778, at No. 28 in the Haymarket, then the picture gallery of Mr. Greenwood, and now the Haymarket Stores. These

lectures were continued with the assistance of Everard Home until the end came. There is considerable difference of opinion as to the number of the pupils who attended. Foot had heard that at some courses there were nearly 50; that in 1786 there were only 12, and in 1788, 18. There is a story that at one course there was only one pupil present, and that in order to be able to begin his address with the word "Gentlemen," Hunter ordered the attendant to bring in the skeleton. No authority is forthcoming for this tale, but all the evidence goes to show that Hunter's genius was unrecognised by his contemporaries.

William Hunter, who had provided each of his brothers with their start in life, who had given to John the opportunity of developing his talents in anatomy, and whose interest doubtless secured for him his Service commission, was no easy master. He had met with opposition to his claims of discovery, and after John's return from abroad the way of the brothers lay apart, though they remained friendly. In 1768 William's influence had procured John's election to St. George's. They were on brotherly terms at the time of John's marriage in 1771, and their relations were manifestly unbroken in 1777, when John was permitted to use the anatomical theatre in Great Windmill-street for his lectures. Before another year had passed some disagreement had occurred between them. I will not weary you with details of the quarrel; suffice it to say that it was the parting of their ways. The estrangement lasted to the end, and though John was permitted to render surgical aid during William's last illness, it is evident that he was not forgiven, for his name was not so much as mentioned in William's will, and everything, even Long Calderwood, was left to others.

Struck down by paralysis, as he was nearing his end William Hunter found words to say: "If I had strength enough to hold a pen I would write how easy and pleasant a thing it is to die." But in spite of the even placidity of the words, they carry with them a sense of disappointment, and of a readiness to depart.

> "Life was bitter. All the faces of the years,
> Young and old, were gray with travail and with tears."

Undoubtedly there was deep feeling on both sides; after their quarrel William had written to his sister, Mrs. Baillie, "I have lived to have my affections much disturbed by ingratitude"; and John, on reminding his pupils of the loss which anatomy has sustained by his brother's death, was obliged to pause and turn his face away, overcome by emotion.

I cannot omit a passing mention of William Cullen, without whose fostering care and interest anatomy would not have found a William Hunter, in the same way that without William Hunter's fatherly protection we should not be assembled here to-day to honour the memory of his brother. On William's death John knew that any worldly expectations he may have entertained were unfulfilled. The lease of the Jermyn-street residence was running out; his museum, the darling object of his life and dreams, required better accommodation, and he decided to purchase the lease of the Leicester-square house and of the premises behind it, which ran through to Castle-street. On the ground between the two he built a lecture theatre and conversazione room, and above them a museum and gallery. He is said to have spent £6000 on the lease and the building. The house in Castle-street provided quarters for his assistants, dissecting and preparation rooms, a printing press, and offices. It was there that his later works were printed.

In William Clift's MS. diary, which found its way in a mysterious manner to Sierra Leone and was rescued from a heap of rubbish, is a plan of John Hunter's house in Leicester Fields. Therefrom we learn the arrangement of the various rooms even to their furniture. On one side of the ground floor was Hunter's study, and on the other his afternoon bedroom. Could we peep into that study in the evening we should see Clift, sitting there from 7 to 11, or even later, copying into the volumes, from dictation, the slips of paper on which Hunter had jotted down his wandering thoughts. There would be the cabinets which contained them; there the s bed which Hunter occasionally used when sudde attacked by angina. In the year before Hunt death his household, there and at Earl's Co numbered 45 persons, including his wife, his son, his daughter.

John Hunter had been appointed Surgeon Ex ordinary to the King, honours were showered u him, and the death of Percivall Pott left him witl a rival in his profession. But two troubles beset I In the first place his health had given way; for s years he had been subject to attacks of gout in feet, and in 1773 he had experienced a strange forn spasm which alarmed both him and his med attendants; it was his first warning of the dis which 20 years later was to strike him down. 1777 he had a second serious attack which lasted days, and, visiting Bath, Jenner went over and him there, and diagnosed the true nature of malady. Henceforward John Hunter lived in const fear of death, recognising the responsibilities which upon him for the support of a family totally unprovi for. He was earning as much as £5000 a year, he saved nothing; everything over and above establishment expenses, which were very lavish, purchase of the Earl's Court freehold, and the l and building of the house in Leicester-square, swallowed up by his museum. The realisation of responsibilities, aggravated by disease, made irritable and impatient of opposition; an unfortu characteristic of both his brother and himself w resulted in their quarrel.

The relations between him and his colleague St. George's, never good, had gradually become wo until they burst out into active and bitter opposit In professional knowledge and in mental capa none of his colleagues on the staff was capable comparison with him. Moreover, while owning hin a pigmy in knowledge, he felt as a giant compa with them, and he despised their apathy and lac enthusiasm in the instruction of the pupils. In endeavour to induce them to share with him lectures, which he considered necessary, he was on every occasion with excuses. One of his colleag said he did not choose to lose any reputation might have in surgery by giving lectures, and ano confessed that he could not see where the art coul improved. In despair of inducing them to bear t share in the instruction of the hospital pupils, informed them that in future he would keep himself the fees of those students who entered u him, this being in direct opposition to the l established custom that all the fees should be div between the four surgeons. The Committee appoi to consider the matter at issue, without consul Hunter, accepted the advice of his three oppone and presented their findings to the board of goverr who thereupon decided against Hunter. Discourt though their treatment of him, he bowed to author "If the proposals meet with the approbation of Governors," he wrote, "it is my business as a ser of the charity to do the duty of my situation."

The curtain rises on the final scene. At a we board meeting on Oct. 16th, 1793, the question a as to the propriety of the admission of two pu who were not provided with the requisite certifica Hunter spoke in their favour, and in the course o remarks made some observation which one of colleagues thought fit flatly to contradict. Hu immediately ceased speaking, retired from the ta and struggling to suppress the tumult of his pass hurried into the adjoining room which he had scar reached when, with a deep groan, he fell lifeless the arms of one of the physicians who chanced t present. At the next meeting of the board mention was made of the tragedy; there was no of condolence. The absence of any official expres of sorrow connotes the bitterness of the hostility he provoked. Such was the passing of John Hur It was suggested in the public press that his st should be placed in St. Paul's by the side of Sar Johnson, Sir Joshua Reynolds, and John How

it in the event he was buried in the vaults of St. artin-in-the-Fields attended by his relations and me of his oldest medical friends. No memorial was ected to his memory until, in 1859, Frank Buckland, ter a tedious and prolonged search for his coffin, as instrumental in procuring for Hunter a last sting place in Westminster Abbey.

His personal property was dispersed ; Earl's Court as sold, and after his debts had been paid a balance some £1500 alone remained. The following year a tition was presented to Parliament praying that the ouse should make such allowance for the collections , upon inquiry, should be thought fit ; when Pitt reported to have said : " What, buy preparations, have not money enough to purchase gunpowder." vo years later a committee was appointed to examine d report as to the character of the collections, their vantages to education, their original cost, and the esent condition and probable duration and preserva- on of the preparations. In the course of the inquiry was elicited that they had cost John Hunter above 0,000 and near 40 years' labour, and Sir William izard gave it as his opinion that " every article bears e stamp of the finger directed by the judgment of a an superior, I believe, to anyone that ever existed a point of practical anatomy." In 1799 the llections were purchased for £15,000 for the use of e public ; the following year they were entrusted to e keeping of the College of Surgeons, and in 1806 ey were moved from Castle-street to Lincoln's Inn elds.

I have but few more words to say. In the brilliant nshine of modern surgical progress, begun by mpson with the introduction of chloroform anæs- esia, and culminating in the magnificent triumph of ster, our eyes are apt to be blinded to the debt we ve to the perseverance and the genius of John unter.

" If you seek his Monument, look around ! "

FESTIVAL DINNERS.

I.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Festival Dinner was held in the College on e evening of Tuesday, Feb. 14th, Sir Berkeley ynihan, supported by the Vice-Presidents and a jority of the Council of the College, presiding er a large company of guests.

After the loyal toasts the company drank in silence the memory of John Hunter. The President then ve the toast of the guests, and, in reference to the gh standing in divinity, literature, art, and law hich some of those guests enjoyed, proceeded to int out that science was the only thing that had vanced during the 200 years that had elapsed ce the birth of John Hunter. In painting, in lpture, and in architecture, as in literature, imme- ate interests had influenced popular taste, but the sults, he thought, would not elicit the profound verence paid to the work of those who lived cen- ries ago. But whatever else was subject to change opinion the union of hosts and guests at feasts s, is, and will be a perpetual feature in society, d the President liked to think of the company that ght have assembled in that hall 200 years ago at festival dinner, if such had been possible. Cheselden d Douglas of " pouch " fame might have been ong the hosts, and John Locke, the philosopher, ter King (Lord Chancellor, as Baron Ockham), his n ancestor, Bishop Berkeley, and Alexander Pope ght have been among the guests, although Dr. ead had put Pope on a diet of asses' milk. While upling the toast with the names of Lord Birkenhead d Dean Inge, he alluded with great feeling to the esence of one other guest, a faithful friend and vant of the College for 50 years, Sir Frederic allett.

The Earl of Birkenhead, who professed profound admiration for surgery without any desire to make close acquaintance with individual surgeons, showed his admiration by being humorously severe on the position which, it seemed to him, was being taken up by modern surgery. Pointing to the claims, always admitted, on behalf of John Hunter, that he had introduced scientific surgery to the world, Lord Birkenhead wondered what the estimate of the successors of the surgeons of to-day would be when it was expressed 200 years later. Those successors might come to the conclusion that, while their own science was perfect, scientific surgery had only begun to-day, nothing before that date counting, and conclusions of that sort implied that during successive periods surgeons had not realised their own defects, nor, which was more surprising, each other's defects, being always of opinion that they were exercising with perfect skill their highly specialised calling. Lord Birkenhead concluded by pointing out that the building in which they were being entertained had gay associations, for it stood on the site of the house of Lord Rochester of frivolous fame, as well as of the old Globe Theatre.

The Dean of St. Paul's, in response, said that he envied the opportunities enjoyed by the modern surgeon for understanding the cases of their patients, and found that in comparison with the surgeon the clergyman was very badly equipped. He wished that it were possible for the clergyman to obtain X rays of the consciences of his patients, so that such offences as the employment of bad language at golf, the making of fraudulent returns for super-tax, and the shooting of foxes could be diagnosed, when the appropriate fines—say payments to the Chancellor of the Exchequer—could be enjoined. He paid a high tribute not only to the skill but to the extreme generosity of surgeons, by pointing out that he had close, though not personal, experience of the virtues to which he was testifying.

The toast of the Hunterian orator was proposed by Sir George Newman, who said that in asking the company to drink to the health of Sir Holburt Waring, the Hunterian orator, he did so with particular pleasure, because he knew how entirely Waring's ideals were associated with the purpose of the Hunterian oration—namely, to keep immortal the memory of John Hunter. A former President of the College, Sir Jonathan Hutchinson, had defined immortality in medicine as the keeping intact by successive links the chain of a great personality ; others had given the claim of immortality to those who engendered seminal ideas, whose seed would be fruitful from generation to generation. Hunter's association of physiology with surgery, as exemplified in the work of Jonathan Hutchinson and of another late President of the College, Sir John Bland-Sutton, was an example of seminal ideas, and a great participant in those ideas was Sir Holburt Waring, as had been made clear by the terms of the Hunterian Oration which they had heard that afternoon.

Sir Holburt Waring, in a brief reply, made no claim for arrival at a perfected surgery such as had been criticised, but repeated the significant expression contained in his Oration that great developments in therapeutics might be expected from biochemistry.

II.

HUNTERIAN SOCIETY.

THIS Society held a festival banquet on Feb. 9th to celebrate the bicentenary of John Hunter's birth. Mr. A. Mortimer Woolf, the President, occupied the chair, and among the guests were the Lord Mayor of London and Lady Mayoress, the High Commissioner for India, the Presidents of the kindred medical societies, and Miss Hunter-Baillie, the last survivor of Hunter's line and his great grandniece. The menu-card was designed and executed by Mr. Thornton

Shiells, the well-known pathological artist, who presented the original to the Society in the course of the evening. It contained Reynolds's famous "snapshot" portrait of Hunter, framed in laurels, with a view of the old home at Long Calderwood above it and one of the Earl's Court "menagerie" below. On either side were drawings recalling some of Hunter's classical experiments, and on the back was the device of a hedgehog. Models of the hedgehog and of the glass jar containing a hen's head with a cock's comb were cunningly executed in ice and exhibited by the chef.

After the loyal toasts had been honoured, Sir Arthur Keith was invited to express his opinion of the menu, and taking its design as his text he related many interesting details of Hunter's life. He pointed out the window of the room where the great man had been born, and the "corbie steps" from which he must have mounted when he rode to London, accompanied by his friend Hamilton. Sir Arthur Keith spoke of his delight at the discovery of the Hamilton-Hunter letters, and mentioned that Dr. Louisa Hamilton had the letters with her in the room, but that he would shoot anybody who tried to get possession of them! He regretted the omission, in the sketch of the house at Earl's Court, of the flock of 15 geese which Hunter had kept to supply him with eggs of a convenient size for his embryological studies. This house had been Hunter's "week-end cottage"—a week-end cottage of forty rooms being no new thing apparently—and the greatest experimental garden in Europe. After his death it had been a gambling den, but had been reclaimed to medicine as a mental hospital.

In proposing "The Hunterian Society," Sir Douglas Hogg, the Attorney-General, drew an eloquent and witty parallel between the duties and aims of the law and medicine which, with the Church, he called the three great healing professions. Congratulating the Society on its international scope, he pointed out that Hunter, through his pupils, had been the founder of scientific medicine in the United States. Between the speeches an unusual feature was community singing, led by Mr. J. Batten, who, as Mr. Mortimer Woolf pointed out in replying to the toast, would in the days of the barber surgeons have been rewarded with a shoulder of mutton and two rabbits.

Mr. W. E. Tanner, secretary of the Society, in proposing "The Lord Mayor and Corporation of the City of London," expressed the Society's gratitude to Sir Charles Batho for identifying himself with their aims. Their association with the City had been a vital factor in their success in carrying on a profitable interchange of ideas with other professions. Sir Charles Batho, in reply, explained that he and Lady Batho had set their hearts on doing all they possibly could for the hospitals of London. "The Guests and Kindred Societies" was proposed by Dr. W. Langdon Brown, and answered by Earl Russell, Sir John Rose Bradford, and Sir Ernest Wild. Sir John Rose Bradford compared Hunter with Harvey, the one a spring and the other a reservoir of science, and referred to Hunter's part in founding the great English schools of medicine. Sir Ernest Wild compared him with John Howard, who had taught the world that even criminals were human, while Hunter had taught it that even surgeons could be humane.

DEATH OF COLONEL CATHCART GARNER, C.M.G., C.B.E.—Colonel Garner, whose death took place at Southsea on Feb. 4th, was born at Dumfries, the son of William Hastings Garner, F.R.C.S., and was educated at St. Columba and Trinity College, Dublin. He graduated in medicine in 1885, entering the Army Medical Department in the following year. He was seconded for service in Egypt, and became deputy director-general of public health administration in Cairo. He rejoined the army at the outbreak of the war, and served in Gallipoli and Egypt, finally becoming assistant director of medical services in Palestine. His decorations were many, including an officership of the Legion of Honour and a Knighthood of Grace of the Order of St. John. His published work chiefly dealt with local epidemics of infectious disease.

Special Articles.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Galashiels Enteric Outbreak.

THE enteric epidemic in Galashiels, a town of so 17,000 inhabitants, began early in January. T cases now number about 100, but the peak is pass and it is reported that the incidence has fallen one case a day. The origin has not yet been det mined, but investigation in detail is proceedi The type is para-B. Whether milk or water ultimately found to be the origin, the outbreak l all the features of a sudden, temporary infection o common medium; for the cases, at the moment, sh a random incidence over the town. In the admir trative stress of accommodating the abnorn numbers detailed investigation takes time. A medi officer of the Scottish Board of Health is in da touch with the medical officer of health, and it m be assumed that no source of probable infection v be left uninvestigated.

Edinburgh Royal Maternity.

In 1927 the intern cases numbered 2094, ext 474, Leith Branch 549, total 3117. This is almost t same as in 1926. The antenatal and postnatal clin show 10,002 visits as against 7395 in 1926. It gratifying to see that the excellent "John Willi Ballantyne Annexe" is so much appreciated. An natal work will soon be a very substantial section the "Simpson's" activities. One wonders more a more why poor Ballantyne had such an uphill fi for some 25 years to secure an effective beginni Everyone wishes the voluntary hospitals well, but t proper expansion is slow. All the greater credit to Nasmyth, for under his generous chairmanship relative pace has increased enormously.

Edinburgh Royal Infirmary.

The pressure on bed accommodation continues such an extent that expansion is urgent. In 1927 number of in-patients was 18,713; of out-patien 61,582. This means an increase of 1689 in-patie Yet, at the end of the year, the waiting-list stood 1995, of which 1203 were surgical. Obviously policy of "coöperation" sketched out more than o by the Secretary of State for Scotland and m explicit in his recent interview with the Brit Hospitals Association, has something very substan to rest upon at the "voluntary" end. The cost bed for 1927 was £155 12*s.* 9*d.*, an increase of £12 This is largely due to the new Radiological Departme which may require separate accounting arrangeme This department is gaining steadily and rapidly favour, as was to be expected. It is interesting, t to note that for the 55 children in hospital, "Certi Milk" was provided at a cost of £450 per annu Four dental surgeons have been added to the staf a wavelet, no doubt, from the rising tide of "den benefit" and dental demand generally. Donati from health insurance approved societies amounted £5948. This is good as far as it goes; but why, a 16 years, the approved societies should remain miserly in their donations is a mystery, when it is v known that, like every other large hospital, the Ro does a very great deal among "insured persons." looks as if little may be expected so long as the pres failure of societies to "pool" or coöperate continu

Voluntary Insurance.

In Scotland, as in England, the contributory sche of old-age pensions at 65 has stimulated "volunt insurance" under the National Health Insurance A "Old age" is a "certainty," in most minds; sickn and death before 65 is, in the same class of mind, o a "risk" and transient. Whatever the psycholo

oluntary insurance in the pre-pension days was a lative failure ; even at present it is a small factor in large scheme ; but it is a symptom of the immense terest provoked by the scheme, which, however, ecessarily leaves many gaps. Recently Mr. Stirling, member of the Scottish Board of Health, xpounded to the Incorporated Accountants' Students' ociety the whole pensions insurance scheme and the lvantages of voluntary insurance. He envisaged at, with the passing of the years, National Insurance ould become more and more an accepted and normal ature of our social system, and that professional orkers would, on ceasing to be compulsorily insured, ect to remain within the scheme as voluntary ntributors.

The Lord Provost's fund for the building and endowent of the new Royal Infirmary has almost reached 84,000 of the £400,000 asked for.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Some Paris Health Statistics.

FRANCE occupies an unenviable position in interational tables of birth- and death-rates. As a French riter has put it : " One is born there less frequently id one dies there more frequently than in many her countries comparable in other respects." It is easant, therefore, to find that the health record of aris is, on the whole, good, being considerably above at of the country as a whole. This is all the more rprising in view of the overcrowding which exists certain quarters of the capital, but there is no ubt that Parisians benefit very largely from the entiful supply of parks, gardens, and open spaces hich " la ville lumière " possesses, and that this utralises to some extent the bad housing conditions. he death-rate in Paris in 1925 was 14·7 per 1000 opulation, compared with 18·1 per 1000 for the rest France. This is a great improvement on previous gures ; in 1912 the Paris death-rate was 16·3, and 1900 19·6. The birth-rate in 1925 was 16·2 per 1000, most the same as in 1912, although the general rth-rate has fallen considerably. Compared with her European cities, Paris has a higher death-rate an London, Brussels, Amsterdam, or Vienna, but a wer one than Budapest, Madrid, and Milan. Its rth-rate is higher than that of Brussels, Vienna, and dapest, and about equal to that of Milan. An alysis of the causes of death shows a decrease in ost diseases since 1900. Deaths from cancer have creased, and those from diseases of the heart and dneys remain about the same. The death-rate for phoid fever has fallen from 0·35 per 1000 in 1900 0·04 in 1922, for pulmonary phthisis from 3·83 to 37, for respiratory diseases from 3·50 to 2·41, and r infantile diarrhœa from 0·96 to 0·31. Deaths from olence (including suicide) have fallen from 0·64 to 28 per 1000 population, so perhaps the Paris apaches e a dying race, but it is curious to reflect that many ore people die from violence than they do from easles or diphtheria (both 0·05 per 1000). Has the olent Paris taxicab anything to do with this ? fant mortality in Paris is lower than in Brussels, d about the same as that for France as a whole ·7 per cent.), but this figure is nothing to boast out.

The direct influence of open spaces on the death-te is seen in a comparison of the different arron-ssements. The Invalides (VII^{e}) has a death-rate 7·7 per 1000, the Champs Elysées (VIII^{e}) 6·8, the rte Dauphine (XVI^{e}) 7·5, the Plaine Monceau VII^{e}) 9, but the Saine Merri quarter (IV^{e}) jumps 17·8 per 1000, the Salpêtrière (XIII^{e}) to 30·5, ontparnasse (XIV^{e}) to 29·7, and Belleville (XX^{e}) to ·2. A glance at a map will show the relationship tween these figures and the situation of parks and en spaces. On the whole Paris is keeping abreast other large European cities in its fight against bad housing conditions, overcrowding, and consequent spread of infection. The post-war invasion of some quarters of the city by large numbers of foreign immigrant workers has been met by an increase in the number of dispensaries where out-patient treatment can be obtained, and serious efforts are now being made, under the impulsion of the Office National d'Hygiène Sociale, to raise the public health services to the level of modern standards.

Strauss has pointed out to the Académie de Médecine that some 69,000 deaths are preventable in France, chiefly those of infants and those due to tuberculosis. A committee has been appointed to examine the problem.

Hospital Extensions.

The obstetric service at the Hôpital Boucicaut, which has greatly increased, requires enlargement and improvement, which have been provided, together with a radioscopic laboratory.

The Paris Municipal Council has just voted funds for the erection, at the Hôpital St. Louis, of a pavilion for the care of leprosy and of a dispensary for venereal cases. The laboratory, which has proved of special value in the study of parasitic diseases of the skin, is receiving an increase of 6000 francs in the fund devoted to its operation.

The radiographic service at the Salpêtrière has increased to such an extent that it requires enlargement and additional personnel.

The sum of 188 million francs has just been allotted to the repair of four of the larger Paris hospitals, whose condition has become urgently in need of improvement. The hospitals in question are the Broussais, Bichat, Beaujon, and Charité.

Inauguration of an International Medical Centre.

This new enterprise was opened on Dec. 20th at 10, Avenue d'Iéna, Paris, in quarters occupying a part of the house formerly owned by Prince Roland Bonaparte. The new centre places a library, information bureau, reading rooms, and other aids at the disposal of the members, and constitutes a medical club for meetings and interchange on medical questions.

The Association for Developing Foreign Medical Relations, of which Prof. Henri Hartmann is president, is proving of great value as an agency for the extension of French medical interests abroad. Monsieur Charlety, rector of the University of Paris, is assuming an active share in the labours of this organisation. Profs. Achard and Hartmann will supervise a medical exposition to be held next March at Athens.

Plans are maturing for an elaborate celebration next spring of the twenty-fifth anniversary of Charles Nicolle's directorship of the Pasteur Institute at Tunis. A committee is arranging for a fête and for the striking of medals. Those wishing to attend the ceremony at Tunis will be granted reduced fares and travelling facilities, of which particulars may be had from Dr. F. Gérard, 100, rue de Serbie, Tunis.

Deaths of Medical Men.

Besides Prof. De Jong, whose death at the early age of 45 years is a real loss to pharmacology, the medical circle in Paris has just been robbed of Patein, member of the Académie de Médecine ; Keller, radiological chief at the Bicetre ; Leblanc, hospital physician ; Danysz, laboratory chief at the Pasteur Institute and originator of the well-known vaccine, and Henneguy, member of the French Institute and of the Académie de Médecine.

A recent issue of the *Paris Médical* was devoted to the biography of Prof. Gilbert, its founder and first director, and contained a number of articles on different aspects of the man and his work.

The surgical prize awards of the Société de Chirurgie consist of the Edouard Laborie prize of 1200 francs, awarded to Ménégaux, of Paris, for his study of a comparison of surgical and radiant treatment in lingual cancer ; the Duval-Marjolin prize of 300 francs, bestowed upon Barret, for a clinical and therapeutic

discussion of extra-uterine pregnancy; and the Ricord prize of 300 francs, granted to Vanlande for investigation of acquired non-neoplastic stricture of the small intestine.

A special conference for the discussion of social defence against syphilis will be held at Nancy from May 29th to 31st. The questions on the agenda are: (1) frequency and cost of syphilis; (2) education of the public; (3) antisyphilitic dispensaries; and (4) organisation for combating congenital syphilis.

The prevention of diphtheria has proved both popular and effective in France. The vaccine generally employed is the Ramond anatoxin, which is atoxic but actively antigenic, and prepared by treating diphtheria toxin with formaldehyde. The French supply is nearly exhausted and the deficiency cannot be met by the Pasteur Institute for at least two months. Results have been especially extensive and excellent in the fifth arrondissement of Paris.

The French Government has announced the organisation of an extensive expedition to combat sleeping sickness in French Equatorial Africa. The expedition will consist of a corps of 33 experts, working under the direction of the Paris Pasteur Institute, and will especially study eradication of the tsetse fly. Special salaries, exemptions from taxation, and prizes for meritorious work are being provided in the campaign, which will cover a minimal period of five years.

Marage has just presented to the Académie des Sciences an interesting study on Beethoven's deafness, which was seemingly due to lesions of the internal ear only. Diagnosis was based upon tinnitus preceding the deafness, initial deafness for sounds of high pitch, and rapid progression of the loss of hearing.

Gosset, surgical chief at the Salpêtrière, was elected to membership in the Académie de Médecine on Jan. 24th.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Newspaper Medicine.

THE tendency for medical men to supply popular articles to the press is increasing. Lately the Academy of Medicine of Toledo, Ohio, has gone quite seriously into the business. They feel by this means advertising propaganda and the evil effects of cultist literature are counteracted. Articles have for some time been furnished gratis to various publications in the State and even outside Ohio. The Academy of Medicine is now preparing to distribute articles on a business basis. The following extract from an article published in the *Toledo Times* may have a double interest to British medical readers, since it not only illustrates the style of newspaper medicine, but will enable them to see themselves as they are seen by American colleagues:—

More than 15 million people are compulsorily insured in the British isles, and after 14 years of unhappy experience both patients and doctors find the system very unsatisfactory. Some of the reasons for the failure of State medicine in England are: (1) It is an enormous expense to the Government. (2) It encourages perfunctory, inferior service, and inadequate medical treatment. The doctor receives compensation whether his services are good, bad, or indifferent. (3) It develops large numbers of neurotics who run to the doctor with every conceivable ailment, whether real or imaginary. It encourages costly malingering. (4) Public dissatisfaction has resulted in an ernormous increase of quackery and cultism. (5) The people lose the right to select their own doctor. (This one item should condemn State medicine for the United States.) (6) It undermines medical initiative, does not recognise merit, forgets the stimulation of medical research, and tends to paralyse medical progress. (7) It discourages the ambitious youth from the study of medicine and leaves the field to men of inferior talent. In America we cannot afford to retard the progress of medical knowledge by Government control. A scheme, such as the "panel system," is full of restrictions, swamped with intolerable "red tape" and graft. . . .

Spray Coating.

The process of finishing has been revolutionised the last ten years by the development of the compress air spray. This method of applying paint or enamel not without its hazards to health. The Nation Safety Council, taking cognisance of these ris appointed a strong committee representing manufa turers, federal bureaux, and national organisatio which has made a careful investigation and b submitted a majority report. Definite evidence w found of poisoning from benzol from the use of benz lacquer sprays, of lead poisoning, and of silicosis. T evidence of the latter was the least conclusive, bei dependent on the interpretation of radiograms; thus nine workers who had been employed in the sprayi industry for more than three years two gave X r evidence of silicosis, and one of probable silicosis. T committee concludes that an exhaust velocity 200 linear feet per minute offers reasonably effecti protection against benzol. Ordinary respirators a ineffective, but a special type known as a positi pressure respirator, under which the face is bathed pure air above atmospheric pressure, is found to effective when properly designed and operate Periodic medical examinations are recommended be made at frequent intervals. The content of spra in benzol, lead, and silica should be reduced to a held at a minimum.

The Common Cold.

Interest in the ætiology of the common cold h been once more revived through the recent gift $195,000 to the Johns Hopkins University by t Chemical Foundation for research on this subje The fund is named the John J. Abel Fund in hono of the professor of pharmacology, and will be admin tered by professors from the School of Hygiene a the School of Medicine of the University. A somewh novel line of research was recently opened up by t papers of Drs. Volney and Cheney to the Americ Public Health Association. Dr. Cheney finds th colds are not contagious; he failed completely inoculate healthy persons with secretions from ac colds. On the other hand, he finds constantly sufferers from colds a decrease in alkali reserve and increase in bicarbonate tolerance. He is able to indu all the symptoms of a cold by induction of artific acidosis through the administration of ammonium a calcium chlorides, and he can regularly abort colds the early stage or cure them in a slightly later stage alkali therapy. Needless to say, the audience did n accept this thesis without protest, and it is improba that any large proportion of them were convince but the suggestion is perhaps worthy of investigati

MEDICINE AND THE LAW.

A Dilemma in Loyalties.

AN action brought last week at Chester Assi against two medical practitioners illustrates continuous exposure of the medical profession actions for damages based on allegations of negligen A patient was suddenly seized with pain, a doc was summoned who formed the conclusion that trouble was due to a burst gastric ulcer, and the pati was taken to the Chester Royal Infirmary for operati Dr. R. S. Graham, assistant surgeon, conducted operation along with Dr. W. G. Love, the sen house surgeon. A large perforation was fou During the later part of the operation a crisis occurr the anæsthetist giving warning that the patient m be got off the operating-table immediately. Unless wound was closed up forthwith the patient would on the table. Dr. Graham formed his decis promptly, and sewed up the wound while Dr. L injected saline. The patient's life was saved. D Dr. Graham waited while the nurses counted swabs and instruments the man would have di Subsequently when they were counted, one instrum was found missing and the fact was duly report

Thirteen days after the first operation a second operation became necessary, the missing forceps was found in the body; there was no sepsis and it was easily removed, but the patient died. His widow brought an action against Dr. Graham and Dr. Love, relying upon the mere fact of the forceps being left in the body as evidence of negligence. In the circumstances already described and entirely undisputed there was plainly no evidence that the leaving of the forceps was due to want of care. When the defendants' evidence had been fully given the plaintiff's counsel put the widow's case as follows. First, it was negligence that the forceps was left in the body—a fact not rebutted by the defendants; secondly, it was negligence to close up the wound without waiting for the usual complete checking of the number of the 60 or 70 instruments employed; thirdly, there was negligence because the sister who should have been counting the instruments was in fact doing something else—namely, assisting Dr. Love to inject the saline. The learned judge had already stopped the case against Dr. Love against whom there was no possible evidence. He then asked the jury two questions: were they satisfied that Dr. Graham had been negligent, and, if so, were they satisfied that his negligence had caused the death? The jury, after a very brief absence, found for the defendant, Dr. Graham, for whom judgment was accordingly given.

The case is particularly instructive. Dr. Graham was faced with two grave alternatives at the crisis of a desperate operation. By delaying the final stages of the operation while the instruments were formally checked he would have sacrificed the patient's life, but would have protected his own professional reputation against any possibility of litigation. On the other hand, by closing the wound at once and by risking the presence of an instrument in the body, he would give the patient a chance of life though he would expose himself to possible proceedings. Dr. Graham rightly chose the second course and placed his patient's interests before his own. The patient gained some 13 days of life instead of being left to die upon the operating-table while the instruments were counted. No clearer instance could be cited of the doctor's duty being faithfully discharged, and yet his reward has been the anxiety and ordeal of a long awaited trial and the unenviable publicity for which even the clear verdict of the jury is hardly an adequate compensation.

"Audi alteram partem."

MOTOR-CAR ACCIDENTS AND HOSPITALS.

To the Editor of THE LANCET.

SIR,—In your annotation last week you remarked on the pressure upon hospital beds caused by the rapid increase in the number of motor-car accidents. Being impressed by the number of these accidents I kept a record of the cases admitted to the male accident ward at the Northampton General Hospital during the seven months April to October, 1927. This period covers the season when such accidents are most common. The Northampton General Hospital is the principal hospital in the county, serving a town of some 90,000 inhabitants and a wide area of surrounding country.

During the period under review 70 adult male accident cases were admitted; of these patients nine were residents of districts outside a 20-mile radius from the town. Of these 70 casualties 50 were caused by motor-cycles either skidding or colliding with other vehicles; three were caused by cars upsetting or colliding; 11 were pedestrians knocked down by cars; four were cyclists knocked down by cars; one man fell off the back of a motor-van; one man was knocked off a ladder by a car. In this series there were nine deaths, all due to head injuries. One man was transferred to another hospital suffering from paralysis due to fractured spine. Of the nine deaths seven were due to motor-cycle accidents and two were caused by a car knocking down a pedestrian.

Taking the 50 motor-cycle accidents we find:—

7 deaths and 1 case of paralysis; 6 cases of fractured femur; cases of fracture of the leg bones, of which 4 were compound; 3 cases of concussion with or without scalp wounds; case of compound fracture of the humerus; 1 case of fracture of both bones of the forearm; 1 case where the skin was stripped off the back of the hand, necessitating pedicle graft from the skin of the abdomen. There were no amputations.

Cars colliding or upsetting were responsible for one fractured tibia, one fracture of ribs, and one fracture of a cervical vertebra. Cars running down pedestrians or cyclists caused two deaths, fracture of both femurs in one case, concussion in five cases, compound fracture of humerus one case, fractured ribs two cases.

These 70 patients occupied beds for an average period of 25½ days, the total cost to the hospital being £770. The total number of beds at this hospital is 225. After providing beds for special departments there are 70 beds available for adult male surgical cases. Reference to figures already given shows that, for at least seven months of the year, from eight to nine of these beds are continuously occupied by the victims of road accidents.—I am, Sir, yours faithfully,

C. C. HOLMAN, M.B., F.R.C.S.,
Hon. Surgeon, Northampton General Hospital.

Feb. 11th, 1928.

DISPOSAL OF THE DEAD.

To the Editor of THE LANCET.

SIR,—Your leading article last week stresses the care we take to prevent bodies being disposed of. No attention is drawn to the absence of any legal requirement compelling a body to be disposed of—a curious lacuna in our burial law. Most practitioners must have encountered difficult cases. I recall a lone widow, a patient, overpowered by grief and alcohol, who declined to consider her husband dead. She kept the body nice and warm with fires in the room and hot-water bottles in the bed. She poured beef tea into the unresisting mouth. At last, after about a week, during a moment when she was experiencing post-alcoholic depression, I "read the Riot Act," threatening to put in force the powers of the non-existent law by calling in the police, and an interment was effected. Surely we ought to copy countries in warmer climates and fix a limit of time for the disposal of a body.

I am, Sir, yours faithfully,

EDGAR L. COLLIS.

Welsh National School of Medicine, Cardiff, Feb. 13th, 1928.

INFLUENZAL PNEUMONIA OR ENTERICA?

To the Editor of THE LANCET.

SIR,—I am putting on record the following notes, chiefly in order to obtain information from others who may have observed similar cases recently.

A certain amount of influenzal pneumonia was being admitted to the Sunderland Infectious Diseases Hospital, when a case of enteric fever was notified that had been treated for pneumonia till typical spots came out and the Widal reaction was found to be positive 1 in 25. This case was followed by another which had been in contact with the first and also gave a 1 in 25 positive Widal; the patient died. Thereafter over a period of some weeks five patients were admitted as influenzal pneumonia with the following features in common: very ill on admission, moist sounds in lungs, epistaxis before or after admission, abdominal pain, slightly enlarged spleen, typical rose-pink spots on the sixth day fading four or five days later, by the eighth day temperature falling by lysis, feeling of exceptionally well-being by the tenth or eleventh day, though a few spots were still present

or cropping out. Convalescence was exceptionally rapid, the Widal reaction remaining negative for typhoid, paratyphoid A and B. Practically all the cases occurred in adults.

I would ask: Were these cases of atypical enteric fever or abortive enteric or were they cases of influenzal pneumonia with enteric-like spots which rapidly improved on removal from their homes to the purer country air? It is to be remembered that all were obviously very ill on admission, and all quickly improved on admission, though most were admitted on the third day of illness, it was striking how far more rapidly they improved than the cases of influenzal pneumonia in the same ward. On inquiry amongst practitioners in the town I heard of three apparently similar cases.—I am, Sir, yours faithfully,

EUSTACE THORP.
Deputy Medical Officer of Health, Sunderland.

Borough Sanatorium, Feb. 9th, 1928.

TREATMENT OF THE MALARIAS.

To the Editor of THE LANCET.

SIR,—I do not wish to take up your space by entering into a controversy upon the merits or demerits of plasmochin. Dr. Manson-Bahr has, I am afraid, missed the point I tried to enforce. My simile of the goose would, I thought, have appealed even to non-ornithological readers. In quoting me Dr. Manson-Bahr has not put in the full sentence I used. I did not say "will act better than either given alone," but "it is quite possible, of course, that . . . a combination of these two drugs will act better than either given alone, but time only and careful observations will show this." We may leave it at that. The subject is too young yet to dogmatise upon.

I am, Sir, yours faithfully,

G. CARMICHAEL LOW.

Brook-street, W., Feb. 10th, 1928.

THE PRESENT POSITION OF THE VOLUNTARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—I do not wish to trespass personally further on your space, for there are many, I am sure, much more fitted to discuss this question. I must just say that Dr. Little attributes to me several statements I never made. With some of them I agree, with others not. The "20 per cent." statement was not mine. In regard to my "brick," as he genially calls it, I disown it, but I stick to it, if you will pardon me. If Dr. Little really wants to know, let him write to the medical superintendents of London poor-law hospitals and ask them how many spare beds they have. It is quite easy. I can give him a good start myself with 120 or so *extra beds filled* over the proper complement. My statement referred expressly to London. I said nothing about the rest of the country, not having personal knowledge about that; but I think it would be worth while to inquire how many of the supposed surplus beds are in country unions neither situated nor equipped to be useful to the chief centres of population. For the rest I leave it to your readers to judge how far Dr. Little has met the various points raised. I am, Sir, yours faithfully,

J. C. MUIR.

Whipps Cross Hospital, Feb. 10th, 1928.

RECURRENT COLDS.

To the Editor of THE LANCET.

SIR,—May I support Dr. A. L. Grant's letter in your last issue. I also have found, both in my own case and in the cases of others, that I can either prevent, abort, or cut short not only that dangerous condition, the common cold, but influenza also by means of Mr. J. E. R. McDonagh's symmetrical ureas.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY.

Wimpole-street, W., Feb. 14th, 1928.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

RESUMED DEBATE ON THE ADDRESS.

IN the course of the resumed debate in the House Commons on Wednesday, Feb. 8th, on the motion tha humble Address be presented to His Majesty in reply the gracious Speech from the Throne,

Mr. HARRIS said that he had great respect for the Minis of Health, for whatever his faults might be they reali that he had knowledge and experience. They had ho for great reforms from him. Towards the end of 1 the right hon. gentleman produced a most interest and almost an historic document in which proposals w put forward for poor-law reform which were to form basis for consideration and discussion by local authorit In 1926 he (Mr. HARRIS) asked the Government when th proposals would take the form of an Act of Parliame and he was informed that the Government wanted a y for consideration. They had had a year. They underst that the Poor-Law Bill would make its appearance dur 1927, but they were told by the Minister of Health t although he was full of goodwill and good intentions programme of the Government was so crowded with ot matters that there was no time to deal with this import question. Nobody could say that the King's Speech t year disclosed an overcrowded programme. There wo have been plenty of time to deal with the vital question poor-law reform. It was not because the Governm were not prepared. The Ministry had been thinking o the matter for two or three years, and there had b constant conferences with local authorities. He underst that there was something like general agreement. W had the Government run away from this question? was now stated that poor-law guardians were to stay that there was to be no reform. Could not the Governm with their big majority force through Parliament the sche which they thought necessary? Did the Governm want to leave the question to be dealt with by the Lab Party or the Liberal Party because they did not feel t they were competent to deal with it? Having dropped Factory Bill, was it not about time that the Governm really did some constructive work and put forward sc scheme to deal with this thorny social problem? They wo never get a solution of the problem of necessitous a without taking in hand the reform of the poor-law. present poor-law system worked badly throughout country. London had a right to demand that the syst of government should be changed. The present poor- system was gradually breaking up. Through the machin of old age pensions the old people were gradually be taken out of the poor-law, and, thanks to the extensio the Education Acts, a large number of children were r relieved through the machinery of the education authorit All who now remained were the sick and the able-bod The original scheme was that the hospitals throughout country should be transferred to the county authorit That would be a very simple proposal to carry throu and would not require any complicated legislation. E the able-bodied who required assistance were very larg at any rate for a period, taken away from the local re and were paid out of national funds through the machin of the Insurance Act. Did it not seem the natural lin advance to remove from the local rates the able-bodied p or to use the phrase in a scheme put forward by the Minis of Health, to correlate the system of relief with the machin of unemployment insurance? If they took the able-bo poor out of the control of the poor-law guardians, removed the children from their care, and took away old people, there was little work left for the guardians do. The Government, he suggested, were under an obli tion to the nation to translate into a Bill the scheme outli by the Minister of Health in 1926.

Lieut.-Colonel ACLAND-TROYTE urged that one way which the Government could help agriculture was refraining from throwing more burdens on agricultur by Orders like the Milk and Dairies Order, and for Prohibition of Preservatives in Cream. The Governm were quite ready to bring in Orders like these, but when t were asked to introduce an Order to prohibit the importa of condensed skimmed milk they would not do it.

Mr. GROVES raised the question of slum clearances West Ham. Every month, he said, the medical office health of that borough reported that 80 per cent. of houses inspected were not considered in all respects reas ably fit for human habitation. The existence of this s property in big boroughs were undermining the healt our future citizens, and increasing the deaths among child He believed that the Government were going to inte themselves in a national campaign for the cure of rheumat

He wished them luck, but there were many other and better ways in which Parliament could approach this question. In West Ham they had people sleeping five, six, seven, and even ten in one room. The less capable an area was of meeting its liabilities the more the National Exchequer imposed upon it in its schemes of social reform and public health. They were proud in West Ham of the way in which —irrespective of party—they had tried to approach the problem of restoring tuberculous people to some sort of normal health, but it cost them money. Their fever hospital was one of the finest in the country, but that hospital was overcrowded. The local hospitals could not take in the people who were sick; they had to be sent to poor-law institutions. Their sanatorium was also overcrowded, and they had a large number of people on the waiting list. They did not object to bearing these responsibilities, but if the Government really intended to approach the problem of relieving local burdens here was the place to start. In West Ham nearly 3000 scholars were fed daily by the education authorities. Otherwise they would go to school hungry. They would respond to any help that could be rendered them, because they could not for many more years continue to carry their present burdens on the shoulders of the local ratepayers.

Mr. SNELL said that they had hoped that the reform of the poor-law would be dealt with during the present session. Almost associated with that problem there was another about which he felt the deepest and keenest interest. A year or two ago he served on the Royal Commission dealing with Lunacy and Mental Disorders. They presented to the Government what they considered was a well-balanced, sober, and critical judgment upon a very difficult and a very moving problem, and they had hoped that the Government would have found time to deal with the unfortunate state in which many of their afflicted fellow citizens found themselves under present conditions. There was also the question of housing. Whatever credit they might take for the improvement in housing in recent years the problem could not be regarded in any way as solved.

Mr. Chamberlain's Reply.

The debate on the Address was resumed on the 9th, when Mr. CHAMBERLAIN, Minister of Health, said that it was not a fact that local government was breaking down. It was true that local government had been placed under a severe strain, but he thought it was going to come through. The effect of such conditions as those which existed in South Wales had produced a vicious circle to which attention had been called so often in that House. Unemployment meant increased local charges, and those charges meant a further handicap to the struggling industries of the district. That matter had attracted the anxious attention of the Government. It was obvious, however, that any relief to local rates which involved the shifting of the burden from the shoulders of the ratepayers to those of the taxpayers could not be confined to one or two areas in the country, and anything of that kind must be part of a general and far-reaching scheme. The time had not yet arrived when the Government could make any proposition to the House. But to those who had so often taken part in debates on necessitous areas it would at least come as a message of peace to know that the Government had not ruled out the possibility of some relief of this kind coming within the realm of practical politics.

Mr. LANSBURY said that the Minister of Health had the impudence to say that local government had not broken down. In unions such as Poplar the board of guardians did not exist. They had no power to administer. The nation would reap what it was sowing. Small-pox was a very deadly disease, and so were typhoid and other diseases. The reason why these diseases had not got a hold during the recent depression was because the physique of the people had been maintained. Food was one of the necessary things for a healthy body. The best safeguard against small-pox was——

Dr. WATTS: Vaccination.

Mr. LANSBURY said that vaccination without food would not save anyone from small-pox, and everyone knew it. He would like to ask the hon. Member, who was a good doctor, "Do you agree that muck and refuse should be left about the streets and be removed only once a week instead of twice a week"?—Dr. WATTS: No.

Mr. LANSBURY said that in that case the hon. Member was on his side. He believed that collectively the nation could do what it pleased in the matter of setting right social problems if it would give up the idea that mere wealth was the only thing that mattered.—The debate was adjourned.

PROTECTION OF DOGS BILL.

On Monday, Feb. 13th, Sir ROBERT GOWER presented the Protection of Dogs Bill, a measure "to prohibit the vivisection of dogs." The Bill, which is supported by Lieut.-Colonel Moore, Mr. Bromley, Mr. Macquisten, Mr. Thurtle, Captain Arthur Evans, Mr. Sexton, and Mr. Radford, was read a first time.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 8TH.

Cost of Social Services.

Mr. BECKETT asked the Minister of Health the amount per head of population distributed on the following services for 1926–27: poor-law relief; old age pensions; National Health Insurance benefits; domiciliary poor-law relief; orphans' pensions; contributory widows' pensions; and contributory old age pensions.—Mr. CHAMBERLAIN replied: Information showing the amount expended, per head, of estimated population by poor-law authorities in England and Wales on poor-law relief in the year ended March 31st, 1927, is not yet available, but the amount for the year ended March 31st, 1926, was 20*s.* 7¼*d.*, including 8*s.* 1*d.* on outdoor relief in money and kind. The amount expended, per head of estimated population, by those authorities on outdoor relief in money and kind for the year ended March 31st, 1927, was 12*s.* 0¾*d.* As regards the remainder of the question the figures are:—

	s.	*d.*
Old age pensions under the Old Age Pensions Act, 1908–1924	13	6·7
National Health Insurance benefits	14	7
Orphans' pensions under Widows', Orphans' and Old Age Contributory Pensions Act, 1925 ..	0	1½
Widows' pensions under Widows', Orphans', and Old Age Contributory Pensions Act, 1925 ..	3	0

Old age pensions under the latter Act were not payable till Jan. 2nd, 1928.

Cost of Poor-law Maintenance.

Mr. BECKETT asked the Minister of Health the average daily number of persons maintained in workhouses; the average weekly cost per person; The total amount expended in connexion with the institutions; the number of adults maintained; the number of children under 16; and the total number of officers and staff employed in 1926–27.—Mr. CHAMBERLAIN replied: The latest information available as regards the maintenance of persons in general poor-law institutions in England and Wales (that is, institutions other than those wholly appropriated to the sick and mentally infirm, and establishments for children in cases where separate accounts are kept) relates to the year ended March 31st, 1926, and such of the particulars asked for as can be given, are, in respect of that year, as follows:—

Average daily number of inmates	134,418
,, weekly cost per inmate	24*s.* 2*d.*
Total expenditure in connexion with those institutions	£8,469,749

The average daily number of adults and children in these institutions has not been ascertained, but the numbers on Jan. 1st, 1926, were 123,373 adults and 11,075 children under 16 years of age. I regret that I am unable to give the numbers of the staff employed.

Voluntary Health Insurance Contributors.

Mr. RHYS DAVIES asked the Minister of Health the number of persons who had become voluntary contributors under the Health Insurance scheme consequent upon the passing of the Widows', Orphans', and Old Age Contributory Pensions Act; and, if so, how did the number compare with the actuary's calculations when the Act was passed?—Mr. CHAMBERLAIN replied: The number of persons who became up to the end of 1926 voluntary contributors, consequent on the passing of the Widows', Orphans' and Old Age Contributory Pensions Act, is estimated at 150,000, or about 10 per cent. more than the number assumed in the Government actuary's calculations for the purpose of the Bill.

THURSDAY, FEB. 9TH.

National Health Insurance Funds.

Mr. FENBY asked the Minister of Health what was the total amount of funds invested, directly or indirectly, on behalf of approved societies under the National Health Insurance Act on Dec. 31st in each of the years 1923, 1924, 1925, 1926, and 1927; and, if the information was not available for Dec. 31st, 1927, what was the amount of the funds so invested on the last available date.—Mr. CHAMBERLAIN replied: The approximate amount of funds invested, including the temporary investment of current balances, on Dec. 31st in each of the years specified was as follows:—

1923	£87 million	1926	£113 million
1924	101 ,,	1927	111 ,,
1925	114 ,,		

Slum Clearance Schemes.

Mr. WELLOCK asked the Minister of Health the number of slum clearance schemes sanctioned by his department for the various local authorities in Worcestershire, and the total amount of money granted by his department in each case.—

Mr. CHAMBERLAIN replied: Three slum clearance schemes have been confirmed in Worcestershire, two at Oldbury, and one in the city of Worcester. The annual Exchequer contributions in aid of the schemes have not yet been fixed, but on provisional figures they are estimated at £500 in respect of the three schemes, representing 50 per cent. of the estimated annual loss.

Stimulation of Milk Consumption.

Mr. BUXTON asked the Minister of Agriculture what steps he proposed to take to stimulate the consumption of milk in accordance with his recent statement to the Council of Agriculture.—Mr. GUINNESS replied: The Empire Marketing Board, after consultation with the Ministry of Agriculture, propose to undertake next April a publicity campaign in favour of the consumption of fresh milk. The campaign will extend over six months in the first instance, but it may be continued for a further considerable period, if the preliminary results are satisfactory and if producers' and distributors' organisations then show themselves prepared to devote to publicity for the same purpose a sum equal to that contributed by the Board. I need hardly add that I propose to do all I can to promote this scheme and ensure its success.

Mr. BUXTON: Will the right hon. gentleman endeavour to guard against a price-raising campaign because a rise of price occurred in the case of the fruit campaign?

Mr. GUINNESS: I do not think there ought to be any rise in price. As the right hon. gentleman is aware, there is a considerable excess of milk which cannot find a fresh market at the present time, and that could quite well be absorbed, I should imagine, without any serious effect in a rise in price.

Mr. MONTAGUE: Will the right hon. gentleman make representations to other Ministers as to the discouragement of the consumption of milk likely to be due to the announced reduction in miners' wages?

Colonel HOWARD-BURY: While encouraging the consumption of fresh milk will the right hon. gentleman discourage the importation of foreign condensed milk?

Lieut.-Commander KENWORTHY: Will the right hon. gentleman also discourage the consumption of alcohol?

Dr. DRUMMOND SHIELS: Will the right hon. gentleman see that in this advocacy of fresh milk some measures are taken to discriminate between tuberculosis-free milk and other milk which may be dangerous?

Mr. GUINNESS: There has been a most remarkable improvement in the condition of the milk supplies. The proportion of tuberculous milk is very much lower than it was a few years ago, and I do not think any more can be done than is being done at the present time in the way of improving our supply of milk and avoiding this danger.

Lieut.-Colonel FREMANTLE: Does the Minister propose in this publicity campaign to work with the Ministry of Health, who are naturally able to get at the medical channels of recommending milk and who have already a publicity campaign on hand?

Mr. GUINNESS: We will certainly work in conjunction with the Ministry of Health.

MONDAY, FEB. 13TH.

Beet-sugar Effluent and Public Health.

Major GEORGE DAVIES asked the Minister of Agriculture what progress, if any, had been made towards solving the problem of the disposal of the effluent from beet-sugar factories in such a way as to avoid any menace to the health, sporting facilities, and general amenities of the surrounding population.—Lord EUSTACE PERCY (President of the Board of Education), who replied on behalf of the Department of Scientific and Industrial Research, said: Satisfactory progress is being made with the experiments which are being conducted by the department in the biological treatment of the waste waters of beet-sugar factories. The data accumulated in the course of a semi-commercial scale trial at one of the factories during the manufacturing campaign just closed are now under consideration. While promising results are undoubtedly being obtained, it is as yet too early to say whether the experiments will lead to an economic solution of the problem. It is further understood that at most of the factories additional plant has been installed for the improvement of the effluent.

Miners' Nystagmus.

Mr. THOMAS WILLIAMS asked the Minister of Labour how many ex-miners who had suffered from nystagmus, and who were unable to obtain work, were receiving unemployment pay on the last date for which figures were available.—Mr. BETTERTON, Parliamentary Secretary to the Ministry of Labour, replied: I regret that no figures of the kind asked for are available.

Infection from Domestic Refuse.

Sir ROBERT THOMAS asked the Minister of Health whether any action had recently been taken, or was about to be taken, by his department to urge local authorities to use covered sanitary dustcarts, in order to minimise the risk of infection from refuse blown about the streets.—Sir KINGSLEY WOOD replied: Local authorities are increasingly making use of dustcarts with covers and are encouraged by my department to do so.

TUESDAY, FEB. 14TH.

Health of Railway Dining-car Attendants.

Sir ROBERT THOMAS asked the Minister of Transport whether he was aware that railway dining-car attendants were habitually required to be on the trains for periods up to 48 and 53 hours, with insufficient sleep and great irregularity of meals, in consequence of which there was a great deal of ill-health among these men, particularly tuberculosis and gastric disorders; and whether he would make inquiry of both the railway companies and the employees' representatives regarding the conditions of work on dining cars.—Mr. BETTERTON (Parliamentary Secretary to the Ministry of Labour) replied: I am informed by the Great Western, London, Midland and Scottish, and London and North Eastern companies that there is no foundation for the statement that the railway dining-car attendants are habitually required to be on the trains for periods up to 48 and 53 hours. The conditions of service of the staff on these lines are the subject of agreements with the National Union of Railwaymen, except on a section of the London Midland and Scottish. With regard to the Southern Railway, who do not directly employ dining-car staff, I am making further inquiries, and I will communicate with the hon. Member on the subject as soon as I have further information.

Medical News.

UNIVERSITY OF LONDON.—Dr. Donald Hunter has been recognised as a teacher of medicine at the London Hospital Medical College.

A Chair of Biochemistry, tenable at the London School of Hygiene and Tropical Medicine, is to be instituted, and applications are invited for this as well as for the Chair of Public Health at the same school, and the Chair of Pathology tenable at the London (Royal Free Hospital) School of Medicine for Women.

The University medal at the M.S. examination in December was conferred on Mr. R. M. Walker, of University College Hospital, and the medal at the M.B., B.S. examination in November on Mr. R. S. Pilcher of the same hospital.

A Carpenter medal, together with a money prize, of the value of £20 in all, will be awarded in 1928 by the Senate for a thesis of exceptional distinction in psychology submitted for the degree of Ph.D. between 1925 and 1928.

Applications for grants from the Dixon Fund must be received between April 1st and May 15th.

Applications for grants from the Thomas Smythe Hughes Medical Research Fund must be received between May 1 and June 15th.

The Laura de Saliceto Studentship for the advancement of cancer research, a part time appointment of the value £150 a year, will be awarded shortly. Applications must be received before July 2nd.

The fifteenth election of Beit Fellows will take place on or about July 16th. Applications should be sent in before April 20th.

University College.—The special short course in anatomy and physiology, designed to meet the requirements of the Primary Fellowship Examination of the Royal College of Surgeons, will begin on Monday, March 5th, in preparation for the June examination. Particulars may be obtained from the secretary of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary meeting of the Council held on Feb. 9th, Sir Berkeley Moynihan, President, in the chair, the proposal to send examiners to Canada to hold a primary examination in anatomy and physiology for the Fellowship at Toronto in 1929 was further considered, and a revised scheme was approved. Instructions were given to the secretary to forward a copy of the revised scheme to the Canadian Medical Association for consideration.—Mr. C. H. Fagge was appointed Bradshaw Lecturer for the ensuing year.—Sir Berkeley Moynihan was appointed delegate to take part in the centenary celebration of the Faculty of Medicine Cairo, and the International Congress of Tropical Medicine and Hygiene to be held at Cairo from Dec. 15th to 22nd.—It was reported that an election would take place on Thursday, July 5th, to fill the four vacancies on the Council occasioned by the retirement in rotation of Sir Anthony Bowlby, Sir D'Arcy Power, and Mr. F. J. Steward, and by the death of Mr. Thelwall Thomas; that notice of the election would be given to the Fellows by advertisement and by circular on March 9th; that March 19th would be the last day for the nomination of candidates; and that

oting paper would be sent on April 3rd to every Fellow the College whose address is registered at the College.—he Diploma of Fellow was conferred upon Harry Isaac eitch, M.R.C.S., L.R.C.P., Middlesex and London Hospitals, ho has previously passed the required examinations and as now complied with the bye-laws of the College.—The ouncil conferred diplomas of M.R.C.S. upon 164 candidates, hose names appeared in our issues of Feb. 3rd and 10th, having received licences from the Royal College of hysicians. Thirteen, however, received their membership previous meetings of the Council.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF LASGOW.—At the monthly meeting of the Faculty held n Feb. 6th, Dr. Freeland Fergus, on behalf of Mr. J. B. illiard, presented to the Faculty the surgical pocket-case sed by David Livingstone in his daily work in Africa. In aking the presentation, Dr. Fergus quoted interesting articulars from a letter he had received from Mr. Hilliard, nd deeply regretted the donor's inability to be present, wing to ill-health. Mr. Hilliard had been born in the oyal Infirmary, for his father, as cutler and instrument-aker to the infirmary, had at that time had an official esidence in the precincts of the hospital. It had been at r. Hilliard's suggestion that Mr. W. Ewing Gilmour ad presented to the Royal Faculty the instrument-case hich had belonged to Dr. Beatty, R.N., surgeon on board the *Victory* at the Battle of Trafalgar. It had been character-tic of Livingstone to surmount difficulties; it was character-tic of him, after his day's work was done in the Blantyre ill, to trudge all the way from Blantyre to Glasgow to ttend lectures on chemistry, and then to return on foot o Blantyre after the lecture was over. The same spirit ad been seen throughout his whole life. It had come atural for him to face all the privations and trials which e encountered in carrying out his great work as missionary, xplorer, and philanthropist. The Faculty received the nteresting and unique relic with acclamation.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—quarterly meeting was held on Feb. 7th, when Drs. David uncan Main, Charles John Shaw, Ronald Gray Gordon, nd Thomas Yule Finlay took their seats as Fellows of the ollege. Major Amir Chand, I.M.S., and Dr. James Thomson Dundee) were elected Fellows of the College. Dr. David ees, D.S.O. (Edinburgh), Dr. Premankur De (Calcutta), r. Edward Robt. Chas. Walker (Aberdeen), Dr. J. D. Allan ray (Leith), Dr. Donald Ross (Lochgilphead), Dr. Chas. A. asker (Bournemouth), Dr. Donald Jack (Edinburgh), and r. Alex. H. Rintoul (Kennoway, Fife) were elected members f the College.

WEST AFRICAN MEDICAL STAFF LIST.—The Crown gents for the Colonies have published a revised edition of he West African Staff List, showing appointments and ervices of all medical officers up to Nov. 30th, 1927. The ames are classified alphabetically, by grades, and by olonies. The booklet may be obtained from Waterlow nd Sons, Ltd., or from 4, Millbank, S.W. 1.

LAMBETH GENERAL LYING-IN HOSPITAL.—The Lord Mayor of London last week presided at the Mansion House t a meeting in aid of the appeal for £40,000 to rebuild nd equip the nurses' home and out-patients' department f this hospital. Among the speakers were Mrs. Stanley Baldwin, the Earl of Birkenhead, and Lord Dawson of Penn. The last-named said that he was puzzled as to how the work f the hospital was carried on, the building being ancient, ut of date, and hampered by every kind of mechanical difficulty." It was announced that £15,000 had then been btained towards the required total.

MOORFIELDS ANNUAL DINNER.—The annual dinner f past and present students of the Royal London Ophthalmic Hospital was held at the Langham Hotel on Feb. 8th. ir Wilmot Herringham presiding. About 80 students ere present, and among the guests were Sir John Rose Bradford, Sir James Berry, Vice-Admiral Arthur Gaskell, ir Matthew Fell, Prof. Elliot Smith, and Prof. H. Hartridge. n the course of the evening Mr. C. B. Goulden, dean of the chool, presented a report on the year's work. The number f new students was 120, the total attending being 216. Among the successes gained by students last year were wo diplomas of F.R.C.S. (Edin.) in ophthalmology. For he first part of the D.O.M.S. 43 students presented themelves and 28 passed; for the second part 42 presented hemselves and 26 passed. A new departure had been made y obtaining the service of lecturers outside the hospital o give courses or occasional lectures. Dr. H. M. Traquair, of Edinburgh, had lectured on Perimetry, Prof. Hartridge on he Resolving Power of the Eye, and in the coming term Prof. Elliot Smith and Dr. James Kerr would give courses. It was hoped to extend the usefulness of the school still urther in this direction by adapting a portion of the out-patients' department as a lecture room.

CHELSEA CLINICAL SOCIETY.—The fourth meeting will be held on Feb. 21st at 8.30 P.M. at the Hotel Rembrandt, Thurloe-place, S.W. Dr. E. C. Sundell and Dr. K. E. Eckenstein will open a discussion on What to Prescribe and Why. Guests are invited to the preceding dinner at 7.30 P.M.

ROYAL INSTITUTION.—On Tuesday next, Feb. 21st, at 5.15 P.M., Prof. J. S. Huxley begins a course of six lectures at the Royal Institution on the Behaviour of Animals. The Friday evening discourse on Feb. 24th will be delivered by Prof. George Gordon, on the Lives of Authors, and on March 2nd by Sir Farquhar Buzzard, on the Psychology of the Sick.

HARVEIAN SOCIETY OF LONDON.—The council has selected chronic streptococcal illnesses as the subject for the Buckston Browne Prize, which consists of a medal and £100 for the best essay sent in by Nov. 1st, 1929. The prize is open to any member of the medical profession under 45 years of age, registered in the British Isles or Dominions. Further particulars from the Hon. Treasurer, Dr. G. de Bec Turtle, 81, Cambridge-terrace, Hyde Park, London, W. 2.

UNIVERSITY OF PARIS.—An Easter holiday course of lectures will be held at the Clinique Médicale de l'Hôtel Dieu from March 29th to April 5th. The general subject will be the Blood, and lectures will be given under such titles as "Blood Pressure," "Blood Injections," "Blood Parasites," "Specific Hæmotherapy," and "Blood Groupings." The last lecture of the course will be a demonstration of the "cinematography of the blood."

UNIVERSITY OF VIENNA.—An intensive post-graduate course in neurology and psychiatry will be held from June 1st to July 31st. Systematic classes will be held in English at the neuropsychiatric clinic of Prof. Wagner von Jauregg and at the Neurological Institute of Prof. Marburg. The whole sphere of neurology and psychiatry will be covered in 300 hours, and the fee is $214. Further information may be obtained from Docent Dr. E. S. Spiegel, Vienna, I, Falkestrasse 3. Passport visas are not required for British subjects.

THE Ninth International Congress of Psychology will be held at Yale University in August or September, 1929, under the presidency of Dr. J. McKeen Cattell, of New York. This is the first American meeting; the congress met in Oxford in 1923 and in Groningen in 1926. The hosts hope to be able to arrange for the appointment of foreigners to American lectureships near the time of the congress, so that foreign attendance can be facilitated.

COOKED FOODS AND HOSPITAL PRESSURE.—At the annual meeting of the Rushden (Northamptonshire) Trades Hospital Committee, Mr. C. H. Battle, in calling attention to the increase in the number of patients, stated that two principal factors in the growth were "road traffic and the popularity of cooked preserved foods."

BOMBAY MEDICAL COUNCIL.—The Council is constituted of six members nominated by the Governor of Bombay in council—namely, Sir Temulji Nariman, L.M., F.C.P.S. Bom., M.R.C.P. Edin.; Lieut.-Colonel R. Row, O.B.E., M.D., D.Sc. Lond., L.M.S., F.C.P.S. Bom.; Lieut.-Colonel R. F. Steel, M.B., Ch.B. Dubl., F.R.C.S. Edin., I.M.S.; R. V. Patel, M.D., F.C.P.S. Bom.; Major S. S. Vazifdar, L.M.S. Bom., M.R.C.P. Lond., I.M.S.; and Lieut.-Colonel W. M. Houston, M.B., B.Ch. Dubl., F.C.P.S. Bom., I.M.S.; and six elected members, namely, N. H. Choksy, L.M.S. Bom., F.C.P.S. Bom., M.D. Freib.; Y. G. Nadgir, M.S., F.C.P.S. Bom.; G. V. Deshmukh, L.M.S. Bom., M.D. Lond., F.R.C.S. Eng.; D. M. Gagrat, L.M.S. Bom.; J. Benjamin, Hospital Assistant; and Captain N. H. Kulkarni, M.C.P.S. Bom., B.M.S. At its meeting on Oct. 17th last the council considered the case of a practitioner who had been summoned to appear before it for displaying the signboards exhibiting the words: (1) Laboratory and Vaccine Institute. Blood, Sugar-Test and Examination of Urine, Sputum, Blood, etc.; (2) 606 Clinic., thereby advertising that he adopts in the treatment of certain diseases special lines of treatment. The charge was held to have been proved, judgment being postponed to the next meeting. The council considered an application for the registration of the qualification of L.M. Dubl., granted by the Coombe Hospital, Dublin. As this qualification is not registrable in the United Kingdom, it was not accepted. The council considered an application from the Mysore University for recognition of its L.M.P. examination and decided that it lacked authority to do so as the institution is not mentioned in the schedule of the Indian Medical Degrees Act, nor affiliated to one of the institutions therein mentioned. On consideration of a letter received from a practitioner, the council resolved that in the case of general practitioners the use of the words "physician and surgeon" may be allowed after their names.

Dr. Mary Barkas has been appointed medical superintendent of the Lawn, Lincoln, in succession to Dr. Jane Shortt.

Dr. D. Robertson Dobie was presented on Feb. 6th with a gift of money by his fellow-citizens on his retirement after 27 years practice in the town and district of Crieff.

RESEARCH IN TROPICAL MEDICINE.—The Wandsworth Scholarship, of the value of £370 per annum with travelling and subsistence allowance for work overseas, will shortly be awarded by the London School of Hygiene and Tropical Medicine. Applications must be received by April 30th.

THE LATE DR. ALEX. STUART, OF CRIEFF.—The death of Alexander Stuart, M.D. Edin., is felt by a wide circle in the county of Perth where he practised all his life. Dr. Stuart qualified in Edinburgh in 1892, and held resident appointments at Leith Hospital. He was medical officer to the post-office, to the parish of Fowlis Wester, and referee for a number of insurance offices.

CALEDONIAN MEDICAL SOCIETY.—The Jubilee of this society will be celebrated in Edinburgh on Feb. 23rd and 24th under the joint presidency of Dr. W. A. Macnaughton and Dr. S. Rutherford Macphail, the two surviving founders. The jubilee dinner will take place in the hall of the Royal College of Physicians, Queen-street, at 7.15 P.M. on Feb. 23rd. The annual meeting will be held at the Royal College of Surgeons Hall, Nicolson-street, at 11 A.M. on Feb. 24th, while at 4 P.M. on the same day the University of Edinburgh are giving a reception.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 4TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 386 (last week, 370); scarlet fever, 1938; diphtheria, 1623; enteric fever, 62; pneumonia, 1533; puerperal fever, 64; puerperal pyrexia, 128; cerebro-spinal fever, 14; acute poliomyelitis, 12; acute polio-encephalitis, 1; encephalitis lethargica, 33; dysentery, 5; ophthalmia neonatorum, 91. There was no case of cholera, plague, or typhus fever notified during the week.

The cases of small-pox were notified from the following 23 counties: London, 5 (Camberwell 1, Southwark 4); Bedford, 10 (Bedford); Chester, 1 (Crewe); Derby, 16; Durham, 94; Gloucester, 1 (Mangotsfield); Hertford, 1 (Watford); Lancaster, 18; Leicester, 1 (Hinckley); Lincoln, Parts of Lindsey, 10 (Lincoln); Middlesex, 1 (Hendon); Northumberland, 7; Nottingham, 13; Southampton, 1 (Southampton); Stafford, 1 (Stoke-on-Trent); Warwick, 19 (Birmingham 11); Worcester, 1 (Worcester); Yorkshire, East Riding, 1 (Hull); North Riding, 18 (Middlesbrough 16); West Riding, 69; Brecknock, 10 (Brynmawr); Glamorgan, 34; Monmouth, 54.

The number of patients at the Infectious Hospitals of the Metropolitan Asylums Board on Feb. 7th–8th was as follows:—Small-pox, 14; scarlet fever, 1759; diphtheria, 2570; enteric fever, 24; measles, 1363; whooping-cough, 160; puerperal fever, 19 (plus 18 babies); encephalitis lethargica, 75; poliomyelitis, 2; "other diseases," 49. At St. Margaret's Hospital there were 12 cases of marasmus and 12 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 98 (45) from measles, 9 (1) from scarlet fever, 32 (5) from whooping-cough, 52 (8) from diphtheria, 41 (5) from diarrhœa and enteritis under two years, and 81 (8) from influenza. The figures in parentheses are those for London itself. Of the 53 fatal cases of measles outside London, 14 were reported from Bristol, 10 from Manchester, 4 each from Salford, Sheffield, and Plymouth, 3 from Warrington, while the figures from Glasgow and Dublin for the same week were 27 and 13 respectively. The death from enteric fever outside London was reported from Derby. The number of stillbirths registered during the week was 270 in the great towns, including 42 in London.

Western Ophthalmic Hospital, 155, Marylebone-road, N.W.—Sen. and Jun. Hon. Anæsthetist. £1 1*s.* per visit.
Whipps Cross Hospital, Whipps Cross-road, Leytonstone, E.—Asst. M.O. £300.
Willesden Municipal Hospital, Brentfield-road, Neasden, N.W.—Res. M.O. £150.
Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.—Hon. Anæsthetists.

The Secretary of State for the Home Department announces a vacancy for a Medical Referee under the Workmen's Compensation Act for the districts of the Chester, Holywell and Flint, and Mold County Courts. Application for the post should reach the Private Secretary, Home Office, Whitehall, S.W. 1, not later than March 3rd.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Whitehaven (Cumberland); Chepstow (Monmouthshire); Clynderwen (Pembrokeshire); Montgomery (Mongomeryshire); Oakham (Rutlandshire); King's Lynn (Norfolk); and Newburgh (Fifeshire).

Births, Marriages, and Deaths.

BIRTHS.

ANDERSON.—On Feb. 11th, at a nursing home, Bedford, the wife of Dr. J. J. H. Anderson, of a son.
BURN.—On Feb. 6th, at Old Friars, Richmond, Surrey, the wife of Dr. J. S. Burn, of a son.

DEATHS.

BASCOMBE.—On Feb. 5th, at The Avenue, Colchester, Edwin Cecil Dare Bascombe, M.R.C.S., L.R.C.P. Lond., L.D.S. Eng.
BENNETT.—On Feb. 7th, at Morpeth-mansions, S.W., Francis Dillon Bennett, M.R.C.S., L.R.C.P., Chevalier de la Légion d'Honneur.
COHEN.—On Jan. 4th, at his residence, Macleay-street, Sydney, N.S.W., Algernon Aaron Cohen, M.D., M.R.C.S. Eng., in his 72nd year.
LLOYD JONES.—On Feb. 6th, 1928, at "The Lings," Radcliffe-on-Trent, Samuel Lloyd Jones, M.R.C.S., L.R.C.P., Medical Superintendent of the Notts County Mental Hospital for 19 years. During the war Lieut.-Colonel in the R.A.M.C.

*N.B.—A fee of 7*s.* 6*d.* is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

THE GORILLA'S BED.

Dr. N. A. Dyce Sharp, in a paper contributed to the *Proceedings* of the Zoological Society, Part 4, 1927, describes a habit of the great African anthropoids that has very rarely been recorded. Both chimpanzees and gorillas, he says, have a most human love for a bed. All chimpanzees sleep in trees 30 or 50 feet above the ground, where they make small untidy beds something like a stork's nest, but the male gorilla sleeps on the ground, and his bed is a far more elaborate affair. It is situated where he can see the nests of his wives and young offspring, whom he directs, according to some accounts, to their respective trees. Dr. Dyce Sharp found that he could always see the wives' beds from every old male's couch in which he had lain. Considering that no gorilla ever sleeps twice in the same bed, he goes to a great deal of trouble in making it. He selects carefully a site where he can break down several young saplings; over these he places stout branches brought from neighbouring trees, and covers this frame with a foot's thickness of twigs and leaves. The completed bed may measure 9 ft. by 6 ft., and always has a stout tree at one side of it, against which the gorilla may lean. The wives select a fork in the tree assigned to them, and make their beds with material from within reach. The only time a gorilla sleeps two nights in the same bed is when a newly born infant is too weak to hold on to the hair of its mother's chest. Dr. Dyce Sharp once came on a party which had been cut off on a small island during the rains. In spite of the confined space, they insisted on making themselves fresh beds each night, even though many of them were contiguous. The old male moved a few yards each night, while the females shifted to another fork of the same tree. The gorilla is a vegetarian and moves chiefly on all fours, so he does not resemble man very closely, except in this habit and in the length of his female's gestation period. Man, when living in the wilds, does not always insist upon a fresh bed each night, but it is recognised that the most efficient and best-adapted soldiers and travellers are those who expend what may seem a disproportionate amount of energy in making themselves comfortable at night. An appreciation of the value of sound sleep, and the necessity of evading enemies, are no doubt the basis of this queer instinct of the gorilla.

ILLUMINATION FOR HAND-TYPESETTING.

LAST year a report was issued on the optimum illumination required for typesetting by hand ("composing") in the printing industry. This was found to be approximately 20 foot-candles, an amount much higher than that usually found in printing offices at the present time. In that report no attention was paid to the almost equally important matter of distribution of the light over the working area. This is the subject of the present report[1] which compares the efficiency of different systems of lighting in common use. Local lighting by itself does not compare favourably with the other methods employed, the compositors finding the glare from the lamps very trying. A special local lighting fitting designed to eliminate glare is more accurately described as localised general lighting and the production, when this fitting was used, was practically equivalent to the average production with indirect lighting. It must be understood that the experiments were made with the same illumination on the working plane from each system tested. This was regulated to give about 10 foot candles—i.e., only about half the optimum—so as to allow for a rise as well as a fall in the efficiency of working. The general conclusion is that a considerable amount of general illumination in composing rooms is necessary to secure the best results. It is important to reduce glare, which is especially apt to be troublesome when the type is new. A combination of general and local lighting in which the two types of source will give approximately the same proportion of the total illumination is to be recommended. When glare from new type is complained of it is suggested that some method should be tried for partially ageing the type before it is put into use.

BENACOL IN THE TREATMENT OF PRURITUS ANI.

THIS distressing complaint, particularly common in private practice, is usually approached with apprehension, for the cause is rarely apparent. The majority of cases have already been examined in vain for hæmorrhoids, fissures, worms, excess of streptococci in the fæces, glyc uria, tabes, and a heterogeneous group of other kno causes, so that little remains but to treat symptomatica and in rare cases to cure permanently. Most ointme have already received a trial, and if X rays and radium h now failed, the physician may have to acknowledge that can do no more. Surgical measures include the inject of absolute alcohol at the muco-cutaneous junction, and excision of affected areas, Whitehead's operation. B these procedures necessitate general anæsthesia, the for perhaps on several occasions, and both may give relief a short time only.

According to three American authors[1] the injection benacol, which, they state, consists of "equal parts of pa amino-benzoyl-ethanol-benzoate and phenmethylol in eq parts of rectified sweet almond oil," may be helpful. T technique does not appear to differ from that advised the alcohol injections, but no anæsthetic is required, and treatment is quite painless if not more than 1–2 c.cm. oil are injected slowly. No complications were met w in 25 cases. A brief analysis of these, as regards sex, a duration of symptoms, and number of injections, is s mitted, and it arouses confidence to observe that no single cure is claimed. Two showed "very marked impro ment," while 22 are described as "improved," and one "slightly improved." A drug with this record deser very careful and prolonged trial, even though, as we susp the results are simply due to the contained phenyl radi and not to the complex structure of the whole molecul

THE NATIONAL CHILDREN'S HOME AND ORPHANAGE.

THE story of the fifty-eighth year of the National Childr Home is told in a little book et called "Builders of City," which is fully illustrated by photographs of childi great and small, at work and play. The examples of ca admitted during the year show that there is a refresh absence of red tape when the need is urgent. Nearly 20, children have been through the various branches, of wi there are now 30. The basis of organisation is the fan group, but the ten larger ones are self-contained li villages, containing between 100 and 300 children ea The Nautical School at Penarth prepares boys for the n and merchant service, and the Chipping Norton bra is a special home for crippled children. At Harpende a children's sanatorium, while there is a convalescent h at Ribblesdale. A new children's hospital at Highb provided by the gifts of the Young Leaguers' Union, started during 1927 and will be opened this year. As n of the hundreds of young men and women leaving the ho every year have no parents or friends to start them off in t careers, vocational training plays a large part, and they taught thoroughly the trade of their choice: bootmak carpentering, tailoring, baking, farming, or whatever may be. The report is in itself a fine tribute to the worl the children's home printing house. The girls are trainec shorthand typists, teachers, nurses, dressmakers, and in various branches of household work. At the end of year there were 3976 children under supervision, and 66 e grated to Canada during 1927. The dietary has been caref revised and brought into line with modern requirements.

THILOCOLOGNE.

THE advantages of starting induction of anæsthesia v a vapour that is not unpleasant to the patient are v obvious. For most people the very dilute vapour with wl an anæsthetist begins an open administration is efficien ensuring free and willing inspiration. It is not alw satisfactory, however, especially with young children, drips of pleasant scent of some kind or another are o used as a preliminary lure. Thilocologne, which is e chloride impregnated with eau-de-Cologne, offers a venient method of attack in these circumstances. ethyl chloride smell is effaced with remarkable success, spray smelling almost completely of eau-de-Cologne, at the same time the ethyl chloride's activity is not in fered with. The spraying nozzle is not as satisfactory some other forms, but this can doubtless be impro Thilocologne may be obtained from Messrs. W. Br 41, Great Tower-street, London, E.C. 3.

SAFEGUARDING OF KEY INDUSTRIES.

THE Treasury have made an Order under Section 10 of the Finance Act, 1926, exempting crude cocaine f key industry duty from Feb. 11th to Dec. 31st, 1928, continuing till the latter date the exemption from d (among other drugs) of barbitone, dial, didial, ethy bromide, furfurol, guaiacol carbonate, hydroquinone, tetra-ethyl, lipoiodin, methyl sulphonal, phenacetin, phe zone, phytin piperazine, pyramidon-veronal, salol, sulphonal.

The Influence
OF
PARTURITION UPON INSANITY AND CRIME.

An Address to the Medico-Legal Society, Feb. 23rd, 1928,

BY A. LOUISE McILROY, M.D., D.SC. GLASG.,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF LONDON (ROYAL FREE HOSPITAL).

SINCE the time of Hippocrates mental derangement has been recognised as one of the diseases of pregnancy and parturition. His case-book shows that his patients' symptoms were similar to those with which we are familiar.

For instance, Thasos who had a normal delivery became delirious on the sixth day. This continued until the tenth day when she had lucid intervals. On the eleventh day she recovered her memory, but quickly lapsed into acute delirium. About the fourteenth day she had much wandering, with lucid intervals, followed quickly by renewed delirium. Twentieth day, death. The wife of Epicrates had a normal delivery. On the second day she was seized with acute fever. On the seventh day she became delirious. On the tenth day delirium ceased. It returned on the sixteenth day and continued until the thirty-first day. On the eightieth day she recovered. Another lady, the wife of Dromeades, had similar symptoms and died on the sixth day.

It was not until 1922 that the Infanticide Act relieved the courts from the painful task of finding a verdict of murder against a woman mentally deranged by childbirth who kills her newly born child. I hope to show that the law requires further amelioration in kindred cases. The subject is one of no little importance. Puerperal insanity accounts for 10 per cent. of female lunacy, and we are painfully familiar with the all-too-frequent cases of infanticide and suicide that result from this condition. We also encounter other aberrations, such as indecent conduct and unconquerable aversion to husbands and relations. The records of Broadmoor [1] show that of the total female receptions from 1900 to1924, 42·8 per cent. were child murderers suffering from insanity associated with childbirth, the majority of the crimes being committed during lactation. There were in all 166 cases, about 7 per annum; 94 recovered, 10 died, 4 were transferred, and 58 remained in residence. It is hoped that, owing to antenatal supervision, improved obstetrics, and better care of the nursing mother, this form of insanity will tend to diminish.

THE GENERAL LAW.

To escape punishment a woman pleading puerperal insanity must prove (*a*) that she was suffering from the disease when she committed the offence, (*b*) that she was incapable of distinguishing right from wrong, or was under the influence of a delusion which prevented her from understanding at the moment the nature of the act she was about to commit. For instance, if she killed her child in a state of mania, she would escape under the first alternative of (*b*), because she would be incapable of distinguishing right from wrong. If she killed it under the delusion that it was a mad dog about to attack her, I assume she would escape under the second alternative. On the contrary, if she thought it would be better for the baby to leave this sinful world, and if she should strangle it, she would be responsible. In other words, the law assumes the delusion to be a fact, and if the fact would justify the act of violence then the prisoner would be entitled to a verdict of "Guilty but insane," [2] which results in the prisoner being detained during His Majesty's pleasure. This is provided for by the Criminal Lunatics Act, 1884. As many critics have pointed out, it is difficult to understand how a person can be both insane and guilty. Before the Act was passed, the practice was for the jury to bring in a verdict of "Not guilty on the ground of insanity," which seems more logical. It should be borne in mind that a verdict of "Guilty but insane" can be passed upon a person sane at the time of the trial. A prisoner who is admittedly insane when about to be tried is, of course, unfit to plead, and is therefore detained during His Majesty's pleasure—that is, until he recovers his reason and thus becomes fit to plead.

From this it is plain that a woman suffering from puerperal insanity who murdered her child knowing that she was doing wrong, would be liable to be convicted and sentenced to death for murder unless she were able to avail herself of the Infanticide Act which makes an exception from the general law. On the other hand, if she established a defence of insanity, she would be found guilty of murder, but insane, and locked up during His Majesty's pleasure, so that even in these circumstances she would suffer punishment of no light order. The Infanticide Act provides (Section I.):—

"where a woman by any wilful act or omission causes the death of her newly born child, but at the time of the act or omission has not fully recovered from the effects of giving birth to such child, and by reason thereof the balance of her mind is then disturbed, she shall, notwithstanding that the circumstances were such that but for this Act the offence would have amounted to murder, be guilty of felony, to wit, infanticide, and may for such offence be dealt with and punished as if she had been guilty of the offence of manslaughter of such child."

As a corollary, Section II. entitles a jury to find a verdict of infanticide where the charge is one of murder. In respect of a newly born child, therefore, the mother has a period of absolution. When that period has expired she is dealt with on the same principles as other persons charged with murder.

THE "NEWLY BORN" CHILD.

The Act requires two things—the woman must be mentally unbalanced and the child must be newly born. The absence from the Act of any definition of the term "newly born" has occasioned some discussion. In a case relating to a young woman named Mary Donoghue, heard last November (1927), the Court of Criminal Appeal, consisting of the Lord Chief Justice, Mr. Justice Avory, and Mr. Justice Salter, decided that a child more than a month old was not newly born within the Act.[3] Subsequently, when correcting a statement in a text-book, Mr. Justice Avory expressed the opinion that a child 3 weeks old did not come within the Act. We therefore do not yet know what constitutes a "newly born child" in law except that one more than a month, and possibly 3 weeks, old does not come within the category. In medicine the definition of a new-born child is somewhat vague. Obstetricians look upon the newly born or neonatal infant as one less than 10 days old. But this period is frequently extended to one month for purposes of mortality statistics and diseases. The convalescent period or puerperium of the mother normally lasts 8–10 days. At the end of this time the uterus has become reduced in size to a pelvic organ and the uterine discharge or lochia has ceased. The mother should therefore be normal, but convalescent. Ten days after parturition is usually the time agreed upon for discharge of patients from hospitals, homes, &c. In private practice nurses are engaged for one month—witness the term "monthly nurse"—to look after mother and baby till the end of this period. In no case is the infant looked upon as newly born after one month from birth. A woman ought to be fully recovered at the end of a month from delivery. This might well be the legal standard

[3] Weekly Notes, Nov. 19th, 1927, Cohen's Criminal Appeal Cases, xx., 113–136.

under the Act in its present form. The facts of the case of Donoghue before the Court of Criminal Appeal are of interest :—

The prisoner gave birth to an illegitimate child on the night of August 19th, 1927. She was removed to St. Pancras Infirmary, and there remained until Sept. 3rd, when she was discharged and took a room in the Euston-road. She lived there from the 3rd until the 21st, and while there obtained a situation as waitress in a hotel. She was to begin work on the 21st, and in the early morning of that day she strangled the child by tying a napkin round its neck. She then went to her work, and, upon information being given to the police, was arrested on the following day. In a signed confession she stated that she had killed her child "because," as she said, "I had nobody to mind him and no money."

The prisoner was convicted of murder and sentenced to death, but the sentence was commuted to one of penal servitude for life. I think the decision was right, apart from the newly born point on which it turned. Obviously the Act was not intended to apply to such a case, sad though it was. The prisoner was not suffering from mental derangement due to childbirth when she killed her child. As she herself admitted, her conduct was occasioned by conditions that might have operated with equal effect 12 months instead of five weeks from the birth.

Puerperal Insanity.

Nevertheless, the state of the law is most unsatisfactory so far as it affects cases of puerperal insanity, a term used to denote an abnormal mental state during pregnancy, labour, the puerperium, or lactation. The three chief forms are confusional, intermittent (manic-depressive), and dementia præcox. Latent tendencies are often stirred into action or precipitated by strain, exhaustion or septic intoxication due to pregnancy, labour, or lactation. The attack may come on at any time within at least six weeks after childbirth and may last for days, weeks, months, or even years. The nearer to labour and the more acute the attack, the more likely the patient is to recover quickly and completely. Usually the symptoms are those of the confusional type. The woman may kill her child, although in a dim fashion she may realise that she is doing wrong. She may go about her household duties in the ordinary way and then murder her child without any warning. She may not remember what she has done, and when made aware of her act may show great remorse.

If there is no hereditary taint the prognosis is good, except in the case of dementia præcox, which seldom completely recovers. The condition may, however, recur in subsequent pregnancies. The patient may suffer from delusions, hallucinations, usually of hearing or sight, and may have suicidal or homicidal tendencies, especially regarding the child. In acute cases, especially in mania, these are infrequent, yet it is a common working practice in nursing puerperal cases with mental symptoms that the infant should be at once removed from the mother and that she herself should be kept under constant supervision. After ten days, puerperal insanity is more likely to be melancholic, suicidal, and homicidal towards the infant. In cases of puerperal insanity it should be impossible to apply the ordinary rules relating to criminal acts by the insane. Apparently, as the law stands, a woman suffering from puerperal insanity who killed her child during the first day of its life, when presumably it would be regarded as newly born, would be guilty of the lesser offence of infanticide, whereas if she killed it when six weeks old she would be guilty of murder. Unless she could prove that she did not know that she was doing wrong or was under the influence of a delusion, she might be sentenced to death. To show the absurdity of the distinction, I will quote Mercier's graphic description of puerperal insanity.[4] He says :

"There is scarcely any desire which is stronger, under normal circumstances, than the desire of the mother for the welfare of her new-born infant. . . . Yet there are cases in which this primitive instinct seems to be reversed, and the place of love and self-sacrifice taken by a fury of destructiveness directed against the hapless child." [Incidentally it may be remarked that animals not infrequently destroy their young. Cats and tame rabbits are instances.] "It is a commonplace of alienism that the danger of insanity in childbed is, that the mother will murder her child. . . . The woman in the insanity of childbed is insane, not merely in her perverted desire to destroy her child, but in many other ways as well. The morbid craving to destroy her child is not an isolated manifestation, but it is a part of a very widespread and deep-seated disorder, which is so great, and so manifest, and is exhibited in so many ways, that the infanticidal propensity sinks into a subordinate symptom."

It will therefore be seen that the law is illogical and unjust. It must not be thought, however, that I am advocating the plea of uncontrollable impulse, so strongly condemned by Lord Hewart. With this I have no concern. This is not what is called a psychological question. My remarks are strictly confined to cases of mental derangement due to pregnancy and parturition, which have been recognised by the legislature as justifying special treatment. There can be no doubt that in making this concession Parliament acted in accordance with the feelings and desires of the community at large, displayed by the unwillingness of juries to convict in such circumstances. It may be alleged that the Act was intended to apply only to those cases in which a woman after giving birth to a child destroys it in a moment of mental anguish, although she knows she is doing wrong. If this reading of the Act is correct, it involves great injustice. Why should a woman who kills her child in such circumstances be treated with more leniency than one suffering from puerperal insanity who kills her child at, say, 6 weeks? To quote Lieut.-Colonel Lord [5]:

"Fear of exposure, shame, depression, even misery following the breaking of the moral law should not be confused with the symptoms arising from the disordered mind; such were the reactions of the normal mind—in fact, were direct evidences of it."

It may be said that the general law concerning acts by insane persons is a sufficient protection for sufferers from puerperal insanity. With all due respect I cannot concur in this opinion.

As stated in Taylor's "Medical Jurisprudence," [6]

"The murder of the child is generally either the result of a sudden fit of delirium or a sudden impulse with a full knowledge of the wickedness and illegality of the act. . . . Women have been known to request the attendants to remove the child and have afterwards taken an opportunity to destroy it. Such cases are commonly distinguished from deliberate child murder by there being no motive, no attempt at concealment, nor any denial of the crime on detection."

Puerperal insanity is a well-recognised disease of motherhood, just as much as puerperal sepsis, and should be treated accordingly. A verdict of infanticide is equivalent to one of manslaughter, so that the offender does not escape lightly. If the prisoner relied upon the general law, and succeeded, the verdict would be one of "Guilty but insane," which would for all time brand her as a murderess and involve her imprisonment, perhaps for a long period. Motherhood is a sacred and patriotic service, and no woman should run the risk of being branded as a murderess because she happens to fall a victim to one of the diseases incident to pregnancy.

Lactational Insanity.

The question is further complicated by the fact that puerperal insanity associated with crime most frequently occurs during the later periods of suckling, owing to physical and mental exhaustion. It occurs among badly nourished, overworked, and poorly fed women. It is due to the strain of

[4] Criminal Responsibility, Clarendon Press, 1905.

[5] Jour. Ment. Sci., July, 1927.

[6] Taylor's Medical Jurisprudence, seventh edition, vol. i., p. 881.

nursing, and many milder cases are cured by weaning and general treatment. It is usually melancholic in type; the patient has suicidal or homicidal tendencies, often on impulse. She may cut her throat or strangle or drown her infant. Many cases are difficult to cure and may end their days in an asylum. In criminal asylums a considerable percentage of women are incarcerated because of homicidal acts towards their infants or children due to lactational insanity. This may be due to the fact that during lactation there is less skilled and constant supervision than during the puerperium. It must be recognised that as the acute maniacal non-homicidal type is most common within 10 days of childbirth and the later melancholic, suicidal, homicidal type during lactation, no legal distinction should be made between the various weeks or months when the symptoms occur. Needless to say, a woman afflicted in this way has "not fully recovered from the effect of giving birth" to her child, to use the language of the Infanticide Act. Therefore, she should be entitled to the benefit of its provisions. If the law absolves the mother who commits infanticide upon her 10-day-old child, it should just as readily absolve the depressed mother, who, worn out by lactation, puts an end to her infant's life.

I claim that the words "newly born" should be deleted from the Act, subject to a proviso that its operation should be limited to a period of six or nine months from the date of birth. Unless unduly stretched, this change could not cover a case such as that of Mary Donoghue, but it would afford protection for mothers suffering from what the medical profession recognise as puerperal insanity, and it would also cover cases in which shortly after birth a woman, although not insane, kills her child in a moment of distraction. It is important to mark the difference between the two classes of case. Unhappily, the murder of infants is only too common, but they are usually killed either at birth or very shortly afterwards. Therefore, the extension of the period would in practice be limited to cases of puerperal insanity. I fully recognise that many infants are deliberately made away with and that nothing should be done to weaken the law in such cases. I also recognise that the Infanticide Act opens the door for untruthful excuses. At the same time it is terrible to think that a mother who has the misfortune to be afflicted with this dreadful disease through no fault of her own, and who has the further misfortune to kill her child as a result, should be liable to be convicted for murder, even if she escapes the death sentence by proving that she was mad when she committed the act. It may be said that there is little or no difference between puerperal and some other forms of insanity. I submit that for practical purposes this view is erroneous. Motherhood is a necessity for the race. It is the factor of motherhood that makes the woman insane and causes her, when suffering from a disease due to motherhood, to destroy her offspring. There is a marked difference between a murder committed by a person suffering from general paralysis or even paranoia, and one committed by a mother in the delirium of childbirth or exhausted by nursing.

From time immemorial, the "woman with child" has been singled out for special consideration and protection. The travail of childbirth is universally recognised as one of the greatest ordeals through which a human being can pass. A great part of modern effort is directed to the welfare of the pregnant woman and the care of her young offspring. Therefore, it seems amazing that our law should be in such an archaic state that a woman may be convicted of murder when she kills her child in a moment of delirium.

It will be seen, therefore, that the following points demand consideration: (1) The definition of the term 'newly born" under the Act. (2) Should the law be altered to give more extended protection to the parturient and nursing mother who, when suffering from puerperal insanity, destroys her child?

ADDENDUM.

Since writing the above paper my attention has been directed to a debate in the House of Lords on the Children Bill, 1908. Lord Loreburn, the Lord Chancellor, with the concurrence of the Home Secretary, proposed to insert a new clause providing that—

> Where a woman is convicted of the murder of her infant, and that child was under the age of one year, the Court may, in lieu of passing a sentence of death, sentence her to penal servitude for life or any less punishment.

In supporting the clause, he said that the passing of the death sentence in such cases was a mockery, as such a sentence had not been carried out since 1849. He thought that public opinion was shocked at the idea of the death sentence being passed in cases where it was manifestly inhuman to carry it out, and, on the other hand, it was very much to be regretted that the death penalty should be nominally inflicted when there was no reality behind it.

The clause was opposed by Lord Alverstone, then Lord Chief Justice, who, with the assent of most of the judges, objected to the option proposed by the clause on the ground that the death penalty should be maintained when infants were deliberately killed, and that in other cases it would not be right to place the judge in a position of having to exercise his discretion. He said, however, he would be glad to consider a scheme for the reform of the law whereby the difficulty indicated by the Lord Chancellor, the painful character of which he fully recognised, might be removed. Lord Halsbury opposed the clause on similar grounds. It was ultimately rejected by 42 votes to 36.

I must say I quite agree with this decision. I think the clause went too far, and that any change in the law should be limited to women who are mentally unbalanced owing to pregnancy, parturition, or lactation. In other words, the removal of the term "newly born" from the Infanticide Act, coupled with the proviso I have suggested, would meet the difficulties recognised by Lord Alverstone and the other speakers who opposed the clause.

An Address

ON THE

STATUS OF PATHOLOGY.

Delivered before the British Pathologists Association at their Annual Meeting at Bristol

BY CHARLES POWELL WHITE, M.D. CAMB., F.R.C.S. ENG.,
PRESIDENT OF THE ASSOCIATION.

I HAVE for many years been interested in the question of the status of pathology and the position of pathologists in relation to other members of the medical profession. My interest in the subject arose in the following way. When, in 1898, I was appointed demonstrator of pathology in a medical school, besides the ordinary duties of a demonstrator I had to carry out the diagnostic work for certain sanitary authorities. At that date this did not mean a great deal of work, being limited to the diagnosis of diphtheria and typhoid with occasional cases of plague, anthrax, &c. This outside work, however, acted as a tie so that I was placed in a position inferior to that of my colleagues in other departments. I could not, for instance, obtain the full advantage of the vacations and sometimes, when I took a holiday, I had to provide a substitute at my own expense out of a total income of £150 per annum. I felt that it was unjust that I, alone of all my colleagues, should have this outside work laid upon me without any extra remuneration.

A year or two before that time there was founded in Liverpool a Pathological Diagnosis Society, the

members of which, for a subscription of half a guinea per annum, could have an unlimited number of specimens examined, and reported on, at the laboratories of the University College. I protested against this scheme [1] on the ground that pathologists were consultants and, as such, were entitled to proper fees, and calling attention to the injustice of a surgeon, who might get a large fee for removing a tumour, being able to obtain a report as to its nature from a pathologist for about half-a-crown. This letter drew a curious reply from a medical man who thought that a surgeon would naturally get reports on his private specimens for nothing from the pathologist of the hospital to which he was attached. From a report of the Thompson-Yates Laboratories a year or two later it appears that the average fee per specimen examined under this scheme amounted to about 2*s*., so that in Liverpool the opinion of a pathologist was valued at about one-twentieth the value of the opinion of a physician or surgeon, without counting the expenses involved in the investigation. That is a good example of the contempt with which pathology was regarded 30 years ago. In 1900 I again drew attention [2] to the claim that pathologists ought to be regarded as consultants, and I protested against the way in which certain associations and societies were carrying out pathological work for fees which were wholly inadequate and without any restrictions as to the ability of the patient to pay the ordinary fee. Since then I have, from time to time, written other letters to the medical journals on similar lines. I have also tried to persuade the Pathological Society of Great Britain and Ireland to approach the universities with a view of inducing them to admit pathology as a subject for science degrees.

Status of Pathology as a Science.

This question has two aspects—viz., the status of pathology as a science and the status of those who practise clinical pathology. Let me here interpose a few words about the term *clinical pathology*. Some academic pathologists regard this term as a misnomer and claim that those who practise this branch of medicine should not term themselves pathologists. No doubt there is a difference between academic and clinical pathology, but the difference is no greater than that between pure chemistry and applied chemistry or between pure and applied mathematics. Academic pathology is a pure science and is concerned with the changes that take place in diseased organisms. Clinical pathology consists in the application of this science to the diagnosis and treatment of disease in individual patients. Clinical pathology must always be founded on a basis of academic pathology as are the various branches of applied chemistry on the basis of academic chemistry. All these branches of chemistry are, however, called *chemistry* however much that term may be qualified, and I see no reason why the term *clinical pathology* should not similarly be in use. Personally I think the term is a very suitable one because it clearly expresses what it means—namely, the application of pathology to clinical practice. It is an old-established term with a definite meaning, and it would be difficult to find a better one. The term *pathology* itself must embrace the whole subject of pathology and cannot be restricted to that part of it which is utilised in clinical practice. Those who practise this branch of medicine should call themselves *consulting pathologists*, or there is no reason why they should not employ the simple term *pathologists*.

Pathology has always been neglected by universities which, while providing special instruction and degrees in anatomy, physiology, &c., have restricted instruction in pathology to the amount which is required by the general medical student and have failed to make provision for those who wish to make pathology their life-work. When the University of London took over University College it refused to take over the department of pathology as an integral part of the College on the same terms as the departments of anatomy and physiology. Pathology is a science as much as any other branch of biology, and there can be no doubt that it is the duty of universities to provide special instruction in pathology as they do in other branches of science. There has been an improvement in this respect recently, and it is now possible to take pathology as a subject in Part II. of the Natural Science Tripos at Cambridge, and it is also possible to obtain science degrees in pathology at Glasgow.

Status of Those who Practise Pathology.

Just as universities have neglected pathology as a science so the medical profession has refused to recognise clinical pathology as a special branch of medical practice. Clinicians have tended to regard pathology somewhat with contempt as a subject fit only for the most junior member of the staff of an institution, and it used to be common to see advertisements of institutions requiring "fourth (or fifth) assistant medical officer and pathologist." Asylums were the worst offenders in this respect, and the junior member of the staff of such an institution could not obtain promotion without surrendering his occupation of pathologist. Such advertisements are not so common now as they used to be, but they have not entirely disappeared. There has, in fact, been a tendency for clinicians to regard pathologists as their servants rather than as their colleagues. The work of a pathologist has been regarded as consisting in the performance of certain tests required by the physician or surgeon, tests which, while demanding a certain amount of technical ability, are capable of being performed by junior and inexperienced men or even by laboratory stewards. You, who are engaged in the practice of pathology, know that there is much more involved than the mere performance of tests. Whilst there are some tests which are more or less mechanical and the results of which are not open to doubt, there is a greater number of cases the investigation of which requires jugdment and experience in addition to technical ability. The department of pathology which requires the greatest amount of experience is the histological diagnosis of tissues. While the actual preparation of sections is a purely mechanical procedure, judgment and experience are required in the selection of pieces for examination and still more in the interpretation of the sections when cut, yet there are some who seem to think that histological diagnosis can be carried out by bacteriologists and others who have had no special training or experience in histology. I have been engaged in histological work now for over 30 years and I still not infrequently come across specimens which I find difficult to interpret. It is not only in histology that judgment and experience are necessary. In all branches of clinical pathology doubtful or equivocal results are apt to occur and the pathologist has to make use of his experience in interpreting them. Clinical pathology thus does not merely involve the simple reporting of results which follow inevitably on the performance of certain tests; it also involves the giving of an opinion formed on the basis of experience.

Improving Position of Pathologists.

The position of pathologists has improved considerably of late years and clinicians are more ready than formerly to recognise them as colleagues of equal standing. There have always been some clinicians who did this, but their number was small compared with those who seemed to regard the pathologist as of inferior standing to the physician or surgeon. The position of a pathologist is a responsible one since on his report may depend the whole of the future treatment of the patient. The British Medical Association has lately been considering the position of pathologists and some important resolutions for improving the conditions of pathological practice have been passed by the Council and the Representative Body. A year ago a meeting was held in London, at the instigation of Dr. S. C. Dyke, to consider the position of pathologists, and at that meeting this association was

[1] Brit. Med. Jour., 1898 ii., 1786.
[2] THE LANCET, 1900, ii., 717.

formed. I think that we have reason to congratulate ourselves on the result of the year's work. We are now recognised as a body to be consulted on pathological matters. We have investigated the actual cost of, and the time taken by, the various investigations which have to be carried out by pathologists and have drawn up a rational schedule of fees based on these figures. We have also approached the various licensing bodies with a view to inducing them to institute courses of instruction and degrees, or diplomas, in pathology.

In the future there is bound to be a considerable increase in the number of men and women in practice as pathologists and the complexity of the activities of the pathologist increases every day. A pathologist has to be at once a morbid anatomist, histologist, bacteriologist, biochemist, and so on in addition to his qualifications as a medical practitioner. He has, in most cases, to work alone and has to carry out investigations in all these branches on his own responsibility. Apart from teaching centres there is little opportunity for team-work in clinical pathology and little opportunity for consultation with fellow pathologists. It is essential, therefore, that the pathologist should have adequate training and experience in all branches of pathology in addition to that which is sufficient for the general medical student. Hence some form of higher graduate or post-graduate training is necessary and also a considerable experience in a hospital laboratory.

Clinical pathology involves two kinds of procedure: (1) the examination of specimens sent to the laboratory; (2) consultations. The ideal procedure would be that the pathologist should meet the patient and the clinician in consultation and, after hearing the results of the clinical examination, he should decide what tests it is advisable to carry out and should give his opinion after performing these tests. This procedure, however, is not always necessary or practicable, and a large part of the practice will always consist in the examination of specimens sent to the laboratory. In this case it is essential that the pathologist should be supplied with full clinical details.

Types of Laboratory.

Laboratories of pathology are of several types: (1) private laboratories owned by the pathologist; (2) laboratories of clinical pathology belonging to associations of medical men or others; (3) hospital laboratories; (4) university laboratories; (5) commercial laboratories; (6) public health laboratories.

Of these different types the last two may be dismissed as wholly unsuitable. Pathological practice should not be subject to the control of commercial firms any more than clinical practice. Public health laboratories should be confined to public health work and should not undertake clinical pathology. Some people seem to think that because a man is a bacteriologist he is therefore qualified to undertake pathological work. This is not the case. Neither in public health nor in commercial laboratories is there the opportunity for gaining experience in pathological work which is essential for the proper practice of pathology, and I think that this association should oppose strongly any scheme which involves clinical pathology being carried out by such laboratories. Private laboratories owned by the pathologist present no difficulties. In some respects they are the ideal form of laboratory, but they are few in number and the expense involved in establishing them is prohibitive in most cases.

Most pathological work is carried on in hospital and similar laboratories by the pathologist attached to the laboratory. The details of the agreement between the hospital, or university, and the pathologist with regard to outside work differ in different places, but all such agreements should be subject to the following conditions:—

1. The pathologist in charge of a hospital laboratory should always have a seat on the medical board of the hospital and, if possible, should be allowed the use of beds for the purpose of keeping special cases under observation.

2. No university, hospital, or any other body owning a laboratory should itself arrange to carry on private work. Apart from research the university should confine itself to teaching and the hospital to the pathological work required for its patients. The hospital or university can, however, give permission to the pathologist to use the laboratory for private work. Every pathological report should be quoted as the report of the pathologist who is responsible for it and not as the report of the laboratory in which the work was carried on, and in all publications in which pathological work is mentioned full credit should be given to the pathologist. All arrangements for private practice should be considered as being between the pathologist on the one hand and the patient, through the intermediary of his medical attendant, on the other as is the case with other consultants.

3. All fees for outside work should be considered the property of the pathologist subject to reasonable charges for the use of the laboratory and apparatus, expenses, &c. The scale of fees to be charged should be decided by the pathologist. The fees should not be lower than those which would be charged if the pathologist had to bear all the expenses himself. No body owning a laboratory should make any profit out of the private work done by the pathologist. In the case of a laboratory owned by an association any dividends payable should be fixed and limited to an amount which would be a fair return for the capital involved.

The National Insurance Scheme.

All these points are of special importance at the present time in view of the probable inclusion of pathological benefit under the National Insurance Act, and the members of this association will have to consider very carefully the terms under which they will undertake such work. One scheme has already been started in this connexion. I do not know the exact details of this scheme, but it appears to be of an objectionable character. It is an arrangement between the insurance authorities on the one hand and a hospital on the other, the insurance authorities to pay a fixed sum per annum for an unlimited number of pathological investigations. In a subject like pathology, where there are so many kinds of investigations requiring very different amounts of time and skill, it seems to me to be very difficult to undertake such work on the basis of a fixed annual sum. If such an arrangement is made at all it should be made with the pathologist himself and not with a hospital.

It is distressing to find that the practice of clinical pathology, and other outside work such as public health bacteriology, by hospitals, universities, or similar bodies, is supported by some leading members of the medical profession and even by some professors of pathology, sometimes on the ground that it ensures an income for the laboratory. Such a practice is not carried out in any other university laboratory, and medical men would be up in arms if it were proposed to adopt a similar procedure in any other branch of medical practice. A short time ago attention was drawn to a scheme organised by a London hospital for undertaking pathological work for outside practitioners, and it was stated that the profits derived from this work would be devoted to reducing the fees charged. This seems to me to be a very questionable procedure. If a pathologist fixes his own fees he is doubtless at liberty to reduce them if he wishes to do so, but he runs the risk of the value of his work being assessed accordingly at a lower level. If, however, a hospital or other institution of good standing reduces fees it will generally be assumed that the fees formerly charged were unreasonably high. What it would really mean would be that the pathologist who worked the scheme would not be getting the amount of remuneration due to him. The fees charged by institutions for pathological work are already, in many cases, much too low.

This commercialisation of pathology is a disgrace to the profession as a whole and I am in hopes that the existence of this association will do something towards removing this disgrace and towards the universal recognition of clinical pathology as a distinct branch of medical practice of a standing equal to that of other special branches of medicine and surgery and governed by the same code of ethics.

BOVINE TYPE TUBERCLE BACILLI FROM SPUTUM IN PULMONARY TUBERCULOSIS.

AN ACCOUNT OF FIVE CASES.

BY W. T. MUNRO, M.D., M.R.C.P. EDIN.

(From Glenlomond Sanatorium, and University College, Dundee.)

With an Addendum by Dr. A. STANLEY GRIFFITH.

BACTERIOLOGICAL investigations show the infrequency of the bovine type of tubercle bacillus in the sputum of patients with pulmonary tuberculosis. Park and Krumweide in America have collected statistics of bovine infections, and could find records of only two cases of undoubted bovine type infections in 680 cases of pulmonary tuberculosis.

In England Stanley Griffith [1] has discussed the validity of the evidence upon which some of the accepted bovine types have been based. Griffith isolated tubercle bacilli of bovine type in three cases out of 275 and pointed out that before any bovine bacilli found in sputum could be accepted as proceeding from the lung there must be rigid precautions to exclude contamination of sputum with bacilli from milk or butter taken by the patient. Further, he emphasised that such bovine type must be obtained from sputa on several occasions.

The present writer, together with Dr. W. M. Cumming, now of Bradford City Sanatorium, in a paper [2] on the virulence of tuberculous viruses, discussed the determination of the bovine type by animal inoculation and relied on the intravenous inoculation of 0·01 mg. into rabbits of between 1000 and 1500 g. in weight. Bovine type bacilli invariably produced progressive generalised tuberculosis, fatal in about 30 days, while the same dose of human type never killed within 90 days. The same paper pointed out that there were relatively few organisms which were atypical either in growth or virulence. In fact the most notable feature about the two types is the uniformity of the type characteristics. Tubercle bacilli seem to retain their characteristics of growth and virulence in a way not usual with other organisms.

Table I. shows that bovine type bacilli are very rarely obtained from pulmonary lesions, that they are

TABLE I.—*Taken from Report of Proceedings of the National Conference on Maternity and Infant Welfare, held in London July 5th–7th, 1927.*

Variety of tuberculosis.	No. of cases.	Percentage of cases infected with bovine tubercle bacilli.		
		0–5 years.	5–15 years.	All ages.

[2] Munro, W. T., and Cumming, W. M.: The Virulence of Tuberculous Viruses, Edin. Med. Jour., March, 1926.

Observations at Glenlomond Sanatorium.

In the past five years five cases at Glenlomond have coughed up bovine type tubercle bacilli. Controls of the virulence experiments have in all cases been done by Prof. W. J. Tulloch, University College, Dundee, and in four of the cases by Dr. Stanley Griffith at Cambridge. Two patients, who have since died, first came under my care in 1921.

CASE 1.—A man of 23 who joined the emergency forces in April, 1921, having never felt ill in his life; six weeks later he was coughing and spitting, and was sent to Glenlomond at the end of May, 1921. He looked decidedly ill and was found to have much disease down one side. No signs of cavitation clinically or by X rays. Muco-purulent sputum showed numerous bacilli. He improved steadily and in 18 months' time was discharged with negative sputum and went back to his work as a miner.

Cultures of T.B. were obtained from his sputum on several occasions, and were always bovine in type.

In January, 1927, he was again looking ill and worn. Examination showed extension of disease and growth of bovine bacilli in the sputum. He refused to come into hospital and died in May, 1927.

The results of the virulence tests of this organism were as follows: 0·01 mg. intravenously killed a rabbit on the thirty-fifth day, the autopsy showing generalised tuberculosis. 10 mg. inoculated subcutaneously killed a rabbit on the sixty-third day with generalised tuberculosis. The generalisation of the disease in both rabbits was short of that usual for infection with a bovine type virus.

CASE 2.—Woman aged 37. This patient had a much longer history of illness. She had had pneumonia in 1908, a mastoid operation in 1913, developed pulmonary tuberculosis in India in 1915, and an ischio-rectal abscess in 1916. She came home in 1918 and was admitted to a sanatorium in the North of England in 1919. She came to Glenlomond in September, 1921, with extensive disease of both lungs, and a discharging ischio-rectal abscess, but left without reason in May, 1922.

At that time the left lung showed extensive fibrotic changes, mostly basal; the right side had rather fewer signs. She died in a sanatorium in England on Oct. 11th, 1924.

Growth of virus from this patient was always dysgonic, but 0·01 mg. intravenously failed to kill the first rabbit inoculated and we killed it after 50 days. Autopsy showed numerous tubercles throughout the lungs, an enlarged spleen studded with tubercles, and many tubercles in the kidneys.

1 mg. intravenously killed a rabbit on the eighteenth day, the lungs being completely collapsed, and studded with tubercles. 0·01 mg. injected intravenously into a second rabbit killed it on the forty-sixth day. Autopsy showed progressive generalised tuberculosis, but not so marked as that observed with a typical bovine virus. 10 mg. injected subcutaneously killed a rabbit after 90 days, and autopsy showed general tuberculosis of the lungs, kidneys, spleen, and other organs.

The results of the virulence tests of this virus suggest that it was an organism with unusually low virulence towards rabbits for a bovine virus.

CASE 3.—A boy of 6, admitted to Glenlomond in January, 1924. He had had a cough for five months and had been in bed for two months with pleurisy of the left side. Examination showed both apices much retracted and the left base especially dull, with bronchial breathing and crepitations. Finger-tips were clubbed and the boy looked ill. He remained at Glenlomond till June, 1927. During the three years his disease showed various outbursts of activity, and the bony structures of the chest altered in contour, but he went home much improved, with no bacilli in the sputum, though he still had a cough, a very dull left base, and markedly clubbed finger-tips.

This virus seemed eugonic, but 0·01 mg. injected intravenously into a rabbit produced lesions much in excess of that usual for a eugonic virus. Growth from the kidney of the rabbit gave a dysgonic virus typically bovine in virulence and growth.

There is no doubt that this was a mixed growth, and that the eugonic element died out on subculture from the rabbit's kidney.

CASE 4.—A youth of 20 years, whose illness began in May, 1923, when he had "pneumonia and pleurisy," left side. He was admitted to Glenlomond in November, 1923. He was afebrile but looked blue, and examination showed considerable collapse of the left lung with weak bronchial breathing and a few crepitations, especially at the base. Throughout the next three years he developed various lesions. Abscesses appeared in connexion with ribs, and the left

estis became affected. This patient is still at Glenlomond, The non-pulmonary lesions are all dry, and the lung condi-ions remain much the same.

A dysgonic virus was obtained from sputum, abscess of b, and testis. Intravenous injection of 0·01 mg. killed a abbit in 35 days, the tuberculosis being general and rogressive.

This virus had the full virulence of the bovine type.

CASE 5.—A girl of 19 admitted to Glenlomond at the end f February, 1924. She had developed a cough in November, 923, and had pleurisy. Right side of the chest was aspirated rior to admission. On admission she looked ill, and the chest owed much dullness down the right side, especially at the ase, where the breath sounds were very weak. The left ase was impaired and showed bronchial breathing with an ccasional crepitation. The abdomen was tense and glands ould be felt, especially in the right iliac fossa. She had ightly hectic temperature and a pulse-rate of about 100. putum was negative on admission.

For the first year she did not improve much; the abdomen emained tender and an abscess appeared over a rib. This as opened, and dysgonic bacilli were obtained in pure ulture from the pus. Growth from sputum was finally btained and was dysgonic, and the virulence test with both iruses proved them to be similar bovine types.

At the end of a year this patient gradually began to mprove, and she left Glenlomond very well on June 30th, 926. She is now married and appears to be quite well.

The question that arises is: Why are bovine type acilli so rarely obtained from sputum? And it does ot seem possible to answer the question satisfactorily n the present state of knowledge.

Bovine type bacilli, and once both types, have been btained in eight instances from the tracheo-bronchial lands of children who have died from tuberculosis in) cases which have been investigated at Glenlomond. hese bovine bacilli must have traversed the lungs efore they reached the tracheo-bronchial glands, and n most instances there was plain evidence at the ost-mortem that the route of infection was by the bdominal glands. Some have maintained that ulmonary tuberculosis of the adult type is always nspired tuberculosis, due to the human bacillus. It not at all likely, however, that the virus was inspired n these five cases, and the history of Case 5 almost roves that the route of infection was abdominal.

The Allergic Reaction to Bovine Infection.

In only one instance (Case 1) were bacilli numerous, nd this is the only patient who showed the usual icture of chronic adult pulmonary tuberculosis of the lcerative type. The X ray of this case differed in o way from that of any ordinary case. Probably the nfection and disease were caused by massive doses of ovine bacilli.

In the other four cases bacilli were always scanty, nd clinically the lesions were more like those of a oot-spread tuberculosis. In three of the cases X ray ms showed the apices clear.

If one accepts the allergic theory of chronic pul-onary tuberculosis—i.e., that chronic ulcerative uberculosis is the result of superinfection with uberele bacilli—then such a chronic process must have een going on in the lungs of all these five patients. here is probably, however, a difference in the way in hich the tissues respond to the bovine and human ypes respectively. We must assume from the number f bacilli in the sputum of Case 1 that the superinfection this patient was the result of a massive dose of ovine type. Case 1 in no way differed from the rdinary case of chronic adult pulmonary tuberculosis, nd showed all along a tendency to ulceration, or, as rause [3] puts it, "central necrosis encroached on eripheral fibrosis." Is the bovine type, then, less rulent to the human subject than the human type, nd what is the allergic state—i.e., the state of esistance of the body—to the bacillus in each case? ere are four patients—three still alive—all of whom owed the root-spread type of disease. It is easonable to believe that there is a more active orotic change going on in the lungs of the patients ho are alive. It is quite possible that superinfection by the human type of bacillus leads to a more violent allergic reaction and more breaking down of tissues, a breakdown such as could only occur with bovine type if they were very numerous.

The allergic state of the patient has much to do with the fibroid character of lesions in the lungs. It is a stimulus to fibrosis if the response is not too severe. A severe response can be obtained by a virus of great virulence.

Experience suggests that there are two factors especially concerned in these bovine infections. One is that the bovine type is not so virulent to the human subject and in itself stimulates fibrosis, while the other lies in the allergic response of the host. This response is a proliferative one, particularly because the bovine type is not so destructive on an allergic terrain. In each of the last three cases any advance of disease in the lungs has only been a short excursion, and fibrotic changes seem to have kept pace with or even to have overtaken the advancing disease. If this reasoning is correct, then superinfection with the bovine type of bacillus leading to chronic ulcerative pulmonary tuberculosis is hardly possible unless the super-infecting dose is very large. That is to say, the allergy occasioned by a previous infection can protect against superinfection by the bovine type but breaks down before the human type of bacillus.

[3] Krause, A. K: Anatomical Structure of Tubercle, Amer. ev. of Tuberculosis, 1927, xv., 156.

OBSERVATIONS ON THE CHARACTERS OF THE TUBERCLE BACILLI FROM FOUR OF THE ABOVE CASES.

BY A. STANLEY GRIFFITH, M.D.VICT., PH.D. CAMB.,
MEMBER OF THE SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL.

Although bovine tubercle bacilli frequently give rise to tuberculosis in the human subject they have rarely been proved to be the cause of pulmonary tuberculosis. In my investigations of the type of tubercle bacilli occurring in the sputum of tuberculous patients I found bovine tubercle bacilli in only three out of 275 cases.

I was therefore much interested to learn that Dr. W. T. Munro, medical superintendent of the Glenlomond Sanatorium, Kinross, had obtained bovine tubercle bacilli from the sputum of five of his patients. At my request Dr. Munro kindly sent me cultures of four of these five sputum strains and also specimens of sputum from three of the patients. I have tested Dr. Munro's strains both culturally and by animal experiment and have also examined the samples of sputum for the presence of tubercle bacilli.

The following is an account of the results of my investigations:—

Examination of Cultures.

CASE 1. *Cultural Characters.*—The strain was dysgonic.

Virulence Tests.—One rabbit inoculated subcutaneously with 25 mg. of the culture died prematurely 27 days later; it showed only a moderate number of minute grey tubercles in the lungs and scattered tubercles in the kidneys, liver, and spleen. A second rabbit inoculated subcutaneously with 10 mg. was killed, when ill, 78 days after inoculation. The post-mortem examination showed local tuberculosis (i.e., a caseous local lesion and enlarged caseous scapular glands), moderate miliary tuberculosis of the lungs, mainly subpleural, and of the kidneys, caseous tubercles in the popliteal glands, and one or two doubtful foci in the liver.

Remarks.—The culture showed the growth characters of the bovine type of tubercle bacillus, but fell slightly below the standard of bovine viruses in virulence for the rabbit.

CASE 2. *Cultural Characters.*—The strain was dysgonic.

Virulence Tests.—Five rabbits were inoculated with the culture, two intravenously and three subcutaneously. The two former, which received 0·1 and 0·01 mg. respectively, died in 15 and 17 days of acute tuberculosis. One of the rabbits inoculated subcutaneously with a dose of 25 mg. died in 114 days of moderate general tuberculosis; the lung parenchyma was partly replaced by irregular caseating nodules and masses chiefly marginal and superficial; the kidneys were enlarged and closely beset with submiliary tubercles and contained also a few larger nodules of wedge-shaped form; there were tubercles in the popliteal glands and tuberculosis of the omentum, both wrist-joints, and some bones. The second subcutaneously inoculated rabbit,

dose 20 mg., was killed when ill, 121 days after inoculation, and showed slight marginal tuberculosis of the lungs, a moderate number of caseous tubercles in the kidneys, one minute focus in the spleen, tuberculosis of both carpal joints, and tuberculous subcutaneous abscesses of the legs. The third rabbit (R. 3097), inoculated subcutaneously with 20 mg., died in 97 days and showed, besides local tuberculosis, scattered miliary tubercles and some marginal caseous patches in the lungs; there were moderately numerous miliary tubercles in the kidneys, two minute foci in the spleen, and one in a popliteal gland; both testes and epididymes, as well as both eyes and lacrymal glands, were tuberculous.

Effect of Passage through the Rabbit on the Virulence of the Strain.—An emulsion of the lung of rabbit 3097 was inoculated subcutaneously into rabbit 3126. This rabbit died in 111 days, but showed only slight general tuberculosis. A culture from the kidney of rabbit 3097 was inoculated subcutaneously into rabbit 3151 (dose 10 mg.). The latter rabbit was killed 257 days later and showed local tuberculosis, slight tuberculosis of the lungs, and tuberculosis of one wrist-joint. A culture from the wrist-joint was dysgonic and was inoculated in a dose of 40 mg. into rabbit 3242. Rabbit 3242 died in 63 days and showed scattered miliary tubercles and a few nodules in the lungs and kidneys, caseous tubercles in the popliteal glands, and two minute tubercles in the spleen.

Remarks.—The culture was typically "bovine" in cultural characteristics, but fell distinctly below the standard of bovine viruses in virulence for rabbits. The virulence was not increased by passage through the rabbit.

CASE 3.—This strain grew luxuriantly on glycerine potato, in this respect resembling an ordinary eugonic human strain. The culture, however, inoculated subcutaneously into a rabbit in a dose of 40 mg. produced in 65 days moderately severe general tuberculosis of a type similar to that caused by bovine tubercle bacilli. Cultures from an axillary gland and the kidney nodule of the rabbit were dysgonic. After preservation in the incubator for some months the original strain yielded only dysgonic cultures, the eugonic element having apparently died out.

CASE 4. *Cultural Characters.*—The strain was dysgonic.

Virulence Tests.—A guinea-pig inoculated subcutaneously with the culture died in 47 days of severe caseo-necrotic general tuberculosis. A rabbit inoculated intravenously with a small dose died in 19 days of acute tuberculosis. An adult nanny-goat inoculated subcutaneously with less than 2 mg. of the culture died in 27 days; the post-mortem showed an infiltrating caseo-necrotic lesion, extensive caseo-necrosis of the prescapular gland, severe miliary tuberculosis of the lungs, and early tuberculosis of the thoracic glands. This strain was typically bovine.

Examination of Sputum.

CASE 3.—Two specimens of sputum were sent to me, one on Feb. 4th, the other on March 24th, 1926. Tubercle bacilli were not found in smear preparations and three guinea-pigs which were inoculated subcutaneously with the sputum remained healthy.

Some months previously Dr. Munro was successful in obtaining from the sputum a culture which he sent to me. The results of my examination are given under Case 3.

CASE 4.—On Jan. 27th, 1926, a specimen of mucinous sputum from Case 4, collected with precautions to avoid contamination with milk or butter, was sent to me. No tubercle bacilli were found in a film preparation of the sputum, which, however, produced general tuberculosis in two guinea-pigs inoculated subcutaneously. Cultures obtained from both these guinea-pigs were dysgonic and identical with the strain obtained by Dr. Munro.

A primary culture from one of the guinea-pigs was emulsified and inoculated subcutaneously into a rabbit which died in 52 days of typical severe general tuberculosis.

Thus two strains of tubercle bacilli, one of which was obtained 13 months after the other, from the sputum of a youth, aged 20 years, were identical in cultural characters and in virulence with tubercle bacilli of the bovine type.

CASE 5.—Specimens of sputum from this patient were sent to me on three separate occasions—namely, on Jan. 27th, Feb. 6th, and March 24th, 1926. No tubercle bacilli were found in film preparations, and none of four guinea-pigs inoculated with the sputum became tuberculous.

Summary and Conclusion.

Of the four strains of tubercle bacilli obtained by Dr. W. T. Munro from sputum three exhibited the cultural characteristics of tubercle bacilli of bovine type and one was eugonic, growing luxuriantly on glycerine potato and egg, like the human type of tubercle bacillus.

Of the three bovine strains two fell, one slight the other more definitely, below the standard of bovi viruses in virulence for the rabbit. The other w fully virulent for the goat, rabbit, and guinea-p A sample of sputum from the latter patient was se to me and I obtained from it, through the guinea-p a bovine culture which was identical with that isolat from the same patient by Dr. Munro.

The fourth or eugonic strain produced progressi "bovine" tuberculosis in a rabbit, the lesions of whi yielded only dysgonic cultures. On subcultivating t original culture, which had been kept for some mont in the incubator, I obtained only a dysgonic stra the eugonic element having apparently perished.

Although I was unable to separate out a hum tubercle bacillus, I have little doubt that the init luxuriant character of the growth indicated t presence of this type in the original culture obtain by Dr. Munro. The negative results of my examinati of two specimens of sputum showed either that t discharge of tubercle bacilli was intermittent or th the disease, whether of the lung or of the bronch glands, had become quiescent.

The results of my investigations of the cultures fr the sputum of four persons with intrathoracic tub culosis are in agreement with those obtained by I Munro.

TRANSPLEURAL EXPLORATION OF THE ŒSOPHAGUS.

BY W. H. C. ROMANIS, M.CHIR. CAMB., F.R.C.S. ENG.,

SENIOR SURGEON TO OUT-PATIENTS, ST. THOMAS S HOSPITA SURGEON TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST;

AND

D. F. A. NEILSON, F.R.C.S. ENG.,

CHIEF ASSISTANT TO THE THROAT DEPARTMENT, ST. THOM HOSPITAL; EAR, NOSE, AND THROAT SURGEON TO THE FREEMASON'S HOSPITAL AND TO THE LONDON FEVER HOSPITAL.

EVERY surgeon who explores a chest after artificial pneumothorax is struck by the remarka manner in which all the intrathoracic organs exposed. When one lung is more or less complet collapsed it is not in the least necessary to take a rib. By making a fairly long incision round the s of the chest between two ribs, cutting through t intercostal muscles and pleura, and by introduci one or two powerful rib retractors of the rack-ar pinion type, so as to force the two ribs apart, a la opening is obtained. Through this the whole ch can be explored, both hands can be introduced, a any necessary surgical procedure can be undertak The essential condition is that the lung should completely collapsed by artificial pneumothorax day or two before the operation. If the operation being undertaken for any non-pulmonary conditi the lung to be collapsed will probably be qu healthy; this can be easily and safely collapsed ir day or two by means of two, or at most three, insertic of gas.

Preliminary Collapse of the Lung.

After several explorations under these favoura conditions we were struck by the remarkably ea approach to the intrathoracic portion of the œsopha and by the possibility of removing a carcinoma by t route. Attempts have not infrequently been made remove œsophageal growths through the chest. nearly every case it has been done by the removal temporary resection of two or three ribs right at t back, approaching the œsophagus through the poster mediastinum after drawing aside and without openi the pleura. We have not found this operation ve satisfactory, either in the living or the dead. Shou it be possible to set free and excise a carcinoma of t œsophagus there will be a considerable risk of infecti

the surrounding tissues from the lumen of the tube, hatever procedure be adopted after the growth has een removed. In fact, this infection constitutes one the gravest features of the operation. If infection ust occur it would be better and less serious if it tually occurred in the pleura, where it can be entified and dealt with by ordinary surgical methods, ther than in the mediastinum, where its diagnosis difficult, its treatment impossible, and its prognosis most hopeless. This is the consideration which has iefly influenced our selection of a transpleural route r approaching œsophageal growths, but other nportant features are the extraordinarily free and sy exposure and the small amount of damage done. fter the intrathoracic procedures are finished the cision between the ribs is closed by two or three yers of sutures, and a few weeks after the operation, xcept for the scar on the skin, there remains nothing show that the chest has been opened. Above all ere is no bulging, deformity, depression, or weakness the chest wall.

Difficulty of Removal and Diagnosis.

Unfortunately very many carcinomata of the sophagus are close to the arch of the aorta and pidly become attached to it or to the bronchi; ese are most unsuitable cases for radical removal. he surgeon must also be prepared to find that many these œsophageal growths consist of a very much rger mass of tissue than might be expected from the sophagoscopic and radiological examinations. In one of the three cases here reported has it been ossible to remove the growth, on account of its tuation. The growths have been very easily exposed nd examined and none of the patients are in any way e worse for the operation or have caused any anxiety fter it. In one female patient the exploration proved at the diagnosis of carcinoma was incorrect, and this atient can therefore be said to have benefited greatly. o little disturbance does the operation cause that it eems justifiable to explore many more cases of sophageal carcinoma, especially those fairly low own, for it is only by this means that we can hope o come across them while they are removable and ossibly curable. As we have not so far been fortunate nough to encounter a successful case of resection of an sophageal growth, our object is simply to demonstrate e possibilities of the transpleural route.

In searching for cases of malignant disease of e œsophagus suitable for an external opera- on, and in which there is a prospect of cure, e surgeon is faced by two unfortunate circum- ances. The first is that growths of the œso- hagus, although common, are very rarely situated that part of the gullet most favourable for xcision—i.e., the section below the arch of the orta and above the diaphragm. Less than 2 per cent. f cases of malignant disease of the œsophagus show e ulcer starting in this neighbourhood. It is, owever, possible that some early cases of malignant isease of the cardiac orifice might come within the ope of operation by the transpleural route, and this a more common site of origin for carcinoma, for it mprises 20–30 per cent. of all œsophageal cancers.

The second adverse consideration is that a patient ffering from malignant disease of the gullet very rely experiences any untoward symptoms until the ew growth has been established for some time. resumably a carcinoma of the wall of the œsophagus very definitely localised for a varying period, and the state of affairs could be discovered early enough e prospect of a cure would be very much enhanced. nfortunately nothing can be done until the first mptom of dysphagia appears. X ray examination nd œsophagoscopy should be carried out on every atient who has even a suspicion of dysphagia lasting ore than three or four days. Although in one of the ses mentioned here there was an error in diagnosis, can be taken as a general principle that in the hands f an experienced surgeon an accurate diagnosis can e made, provided a thorough X ray and direct sophagoscopic examination is carried out. X ray examination alone is insufficient; many growths of the œsophageal wall which give rise to symptoms show no obstruction to the passage of opaque emulsion. Naturally these are the earlier cases, and therefore those most likely to give the surgeon a chance to remove them completely. Although an accurate diagnosis can be made, it is often difficult to tell the extent of the growth, and disappointments may be anticipated.

Three Cases Related.

CASE 1.—Male aged 45. Three months' history of increasing dysphagia. When first seen could only swallow fluids. The X ray showed a typical irregular stricture which seemed to be about two inches long, situated just below, but quite clear of, the arch of the aorta. Œsophagoscopy was performed and a growth found, of which the upper limit was 26 cm. from the upper incisor teeth in the direct line. This distance indicated that the growth was high enough up to be in contact with the arch of the aorta, but the X ray showed it so clearly below the arch that it was thought justifiable to attempt its removal. A portion was removed for microscopy and reported as squamous-celled carcinoma.

Gastrostomy was performed on April 30th, 1926, and thoracotomy, following artificial pneumothorax on May 14th, 1927. At this operation the growth was found tucked below the arch of the aorta, to which it was firmly adherent, and so it could not be excised.

In this case we had the kind assistance of Mr. W. G. Howarth.

CASE 2.—Woman aged 45. Two years' history of increasing dysphagia. The X rays showed an obstruction, apparently two inches above the diaphragm, suggesting an organic stricture rather than a spasm. The patient brought this X ray film from another hospital, and so a second X ray examination was not carried out. This was unfortunate, for it would have included inspection with the fluorescent screen, which would probably have disclosed the true condition.

Œsophagoscopy was performed and an obstruction found at 32 cm.—i.e., at a distance corresponding fairly accurately to the site of the stricture shown by X rays. No ulceration. ? Extra-mural neoplasm. Gastrostomy was not performed on this patient, but on thoracotomy no organic stricture could be discovered. When the patient had completely recovered from the effects of the operation it was found that her swallowing was almost normal, and on X ray screening no œsophageal obstruction could be seen.

This result makes one wonder to what extent, and why, actual benefit is derived in these spasm cases from forcible dilatation of the cardia.

CASE 3.—Man aged 50. One month's history of increasing dysphagia. On X ray examination a shadow was seen round a stricture just above the diaphragm. Diagnosis of new growth involving the cardia. Œsophagoscopy not done.

A gastrostomy was performed, and six weeks later the thorax was opened in the usual way and a large mass found involving the œsophagus just above the diaphragm. The diaphragm was incised, the peritoneal cavity opened, and the growth was found to be more extensive below than above, and to run right on to the stomach.

Case 3 is an example of the good and easy approach to the upper part of the abdomen supplied by the transpleural route with a collapsed lung. This method is, of course, well recognised, but seldom employed. We have found it a valuable route for approaching the right suprarenal body and the upper part of the stomach.

In all these cases Dr. G. T. Hebert was kind enough to do the preliminary collapse of the lung for us.

A MINERS' HOSPITAL.—Eleven years ago the Castleford (Yorkshire) Amalgamated Friendly Societies adopted a suggestion that a maintenance fund for the provision of a cottage hospital should be created by the contribution of a penny a week from the wages of their members. The idea was readily taken up by the miners at the large collieries in the district, and the total contributions now exceed £46,000, which includes £16,000 in large sums given for memorials. The building at Hightown, Whitwood, which, with the site of 11 acres, has cost about £38,000, is now completed. Accommodation is provided for a minimum of 38 beds in four wards, and the equipment is thoroughly modern. Over 18,000 miners and others have made weekly contributions.

EPIDEMIC JAUNDICE IN THE ANDAMAN ISLANDS.

By H. C. BROWN, C.I.E., M.B. Camb., D.T.M. & H.,
MAJOR, I.M.S. (RETD.).
(*From the Wellcome Bureau of Scientific Research.*)

Barker [1] has given an excellent description of epidemic jaundice in the Andaman Islands. The history starts with an account by Chowdry [2] of 588 cases of jaundice and fever, with a mortality of 13·26 per cent., between 1892 and 1901. These cases were apparently indistinguishable from true Weil's disease, except that the onset was not sudden. The patients had nearly all been working in the paddy fields or in the swamps in the jungles. Woolley [3] recorded 40 cases with a 40 per cent. mortality. These cases also were almost all derived from men who had been working in swampy ground. Barker recently recorded several cases which occurred in 1921, and 24 more in the two subsequent years, with a mortality of 24 per cent. for the three years. These were followed by 22 more cases in 1924 with four deaths.

From the symptoms recorded there is nothing definite to distinguish this disease from true Weil's disease. Barker found organisms morphologically resembling *Leptospira icterohæmorrhagiæ* in the urine of three cases, and in liver smears from one fatal case. Numerous guinea-pigs were inoculated with urine and blood from the patients, but none of the animals developed any apparent disease. Barker concludes that the proof that the disease is due to leptospira is incomplete.

Serological Investigation.

During 1927 Dr. H. B. Newham very kindly handed over to me the serum of a case sent from the Andamans by Major J. M. R. Hennessy. This was tested for presence of agglutinins against a London human strain of *Leptospira icterohæmorrhagiæ*, according to the technique of Martin and Pettit.[4] Positive and negative control sera were used; the result of this serum, taken on the twelfth day of disease, was absolutely negative. It is true that this would be somewhat early to expect agglutinins to be present. A portion of the serum was activated by the addition of fresh guinea-pig's serum and adhesion phenomenon tested (Brown and Davis, 1927).[5] This was also negative.

Dr. William Fletcher kindly procured from Prof. W. Schüffner several strains of leptospira from Sumatra, also certain Dutch strains, and shortly after the arrival of these a second batch of sera from the Andamans arrived. The serum from one fatal case, No. 46952, taken on the nineteenth day of disease, was tested by the adhesion phenomenon against the following strains: (1) London human, (2) Moné (a typical Weil strain from Holland), (3) Salinem from Sumatra, (4) Rachmat from Sumatra, (5) Deli A (identical with Rachmat) from Sumatra. With the last two—viz., Rachmat and Deli A, there was a definitely positive result, but the serum was absolutely negative with the other strains. When tested for agglutinins against the London human, Salinem, Moné, and Deli A, only the Deli A strain was agglutinated.

On another occasion the serum of a fatal case, No. 34473, taken on the seventeenth day of disease, was tested by the adhesion phenomenon against (1) a London human strain, (2) a London rat strain, (3) Moné (a typical Weil strain from Holland), (4) Ht (a typical Weil strain from rat, Holland), (5) Rachmat from Sumatra, (6) Salinem from Sumatra, (7) Deli A from Sumatra. The adhesion phenomenon was definitely positive with strains Rachmat and Deli A, and absolutely negative with the remainder. There was not sufficient serum available from th case for the agglutination reaction, and, as the seru itself was toxic to leptospira, it had to be dilute Fresh guinea-pig's serum was added to the dilute patient's serum to activate it.

Identification of the Andaman Organism.

It appears, therefore, that the organism responsib for jaundice in the Andamans is serologically identic with the Rachmat and Deli A strains, and not wit the Salinem strain. Schüffner and Mochtar,[6] in a exhaustive inquiry into the serological relationshi of these various strains, have shown that the Saline strain from Sumatra is serologically distinct from th Rachmat strain, but that the latter is identic from a serological point of view with one huma strain, B.G.O., and two rat strains from Holland These findings explain the fact that the results of th agglutination and adhesion tests between the firs serum sent last year and the London strain wer negative. As the supply of sera was distinctly limited agglutination tests with a greater number of strain was not possible.

Whilst these serological tests were being performed Dr. A. C. Stevenson examined sections of the kidne and liver of No. 46952 and reported as follows:—

Liver.—Some slight degeneration, but nothing ver typical of Weil's disease. Some polymorphonuclear leuco cytosis.

Kidney.—Marked general parenchymatous nephriti localised areas of suppuration, the tubules being distende with pus. This is possibly due to extensive infection by bacillus which is probably a spore bearer. When stained b Levaditi's method, spirochætes are found mainly in tw positions. Many of those found in the cells and in the lume of the straight tubules are morphologically indistinguishabl from leptospira. Others found, occasionally in considerabl numbers, in masses of material staining homogeneously i convoluted tubules seem to be definitely of a differen type, more resembling *S. recurrentis*.

It is interesting to compare the observations o Vervoort [7] who found coarse spirochætes together wit leptospira in the cultures and ascitic fluid of guinea pigs inoculated with the blood of patients sufferin from dengue-like fevers in Sumatra. Knowles, referring to tissues sent to him, says: "Sections o liver and kidney tissue from such cases, stained b Levaditi's method, have been received from th Andamans. These show undoubted leptospira, an the epidemic jaundice of the Andamans must now b considered to be Weil's disease."

We are, therefore, in a position to conclude that th epidemic jaundice of the Andamans is due to a lepto spira which is serologically identical with the Rachma type from Sumatra. Although the Rachmat strai was isolated (Wolff [10]) from a comparatively mild cas with injection of the conjunctiva but no generalise icterus, the mortality in Deli amongst cases with icteru has been recorded (Kouwenaar [9]) as 20 per cent., an Schüffner has found the strain Rachmat to be sero logically identical with Deli A.

I wish to express my thanks to Dr. Newham fo allowing me to investigate the sera in question, an to Prof. Schüffner and Dr. Fletcher for providing m with the necessary strains of leptospira.

Clinical and Laboratory Notes.

NOTES ON THE TREATMENT OF HYPERPIESIS.

By William Bain, M.D. Durh., F.R.C.P. Lond.

Most writers on hyperpiesis suggest that the cause is some toxin circulating in the blood, but about its chemical characteristics they are discreetly silent. Some years ago I found pressor bases in normal urine.[1] They were adsorbed by charcoal and thence removed by heating with dilute hydrochloric acid. The first base was extracted by ether after the filtrate was rendered alkaline with sodium hydrate. After the removal of this base the residue was re-acidified with dilute hydrochloric acid, and having been made alkaline with sodium bicarbonate was extracted with amylic alcohol. We used 130 litres of normal urine in order to obtain quantities sufficient for identification. The first was identified as isoamylamine.[2] The second base could not be identified, as the amount was too small, but it gave a curve very similar to that of p-hydroxyphenylethylamine.

Some years ago I showed that the pressor bases were absent from the urine in most cases of high blood pressure; in a few patients whose systolic pressure was about 180 mm. Hg they were greatly reduced in amount. It is therefore reasonable to assume that their retention in the organism is the cause of hyperpiesis. Why they are not eliminated is a matter of conjecture. A probable explanation is some renal defect, either a functional impairment or the beginning of organic change; but a test to demonstrate this supposed defect is badly wanted. The present renal efficiency tests are not positive unless there are definite pathological lesions of the kidney, and in an early case of hyperpiesis these histological changes have not had time to develop, and therefore it is highly desirable to devise a test that will detect the first approach of renal trouble. The estimation of the urinary pressor bases by the charcoal method is far too laborious, and is utterly unsuitable for clinical purposes.

There are two criticisms of the otherwise excellent urea-concentration test: first, that it cannot detect renal inefficiency until kidney disease is somewhat pronounced; and, secondly, that the rate of absorption may vary in different individuals.

Since the amount of isoamylamine is much larger than any other pressor base in normal urine, its retention in the body plays the chief part in the causation of hyperpiesis. Until we find a chemical agent that will combine with isoamylamine to produce a non-toxic substance which will be excreted by the kidneys we must rely upon palliative measures which may reduce the high blood pressure more or less temporarily. The first and the most important is diet. Since isoamylamine is derived from putrefactive nitrogenous material, beef, mutton, veal, and lamb should be prohibited, but eggs, fish, and fowl may be allowed, because they only raise the blood pressure to a moderate extent. Meat extracts should be absolutely forbidden. Vegetables and fruit have no effect whatever upon the blood pressure. The diet should be considerably restricted in those who lead sedentary lives. Abelous, of Paris, and I, using different methods, obtained exactly the same results regarding the various foodstuffs. In sketching out a diet list it is advisable to ascertain the idiosyncrasies of the patient, as flatulent dyspepsia tends to increase the blood pressure.

Plombières douches in cases of catarrh of the colon produce a diminution of the pressure, probably because they remove putrefactive material.

The high-frequency current has also a depressor effect in hyperpietics, but not in normal subjects. It is supposed to increase metabolism.

Stimulation of the liver by liver packs or by cholagogues lowers the blood pressure in cases of cholecystitis. It has been demonstrated that a normal liver will destroy isoamylamine, and feeding animals with this substance does not produce any pathological change in the vascular system.

Massage under warm water, such as the Harrogate massage douche, without abdominal massage or the needle douche, has a distinct effect in reducing the blood pressure and is particularly refreshing. In some cases Nauheim baths have a slight reducing effect; in others no appreciable lowering of pressure results.

Rest and the avoidance of worry and excitement tend to quieten the nervous system. We know that mental strain sends up the blood pressure. A moderate amount of exercise such as golf (nine holes) or walking is beneficial. After exercise a warm bath is desirable (patients should not stay in it longer than two minutes at a temperature from 94° to 98° F., and should immediately afterwards dry thoroughly with a warm bath sheet). I usually advise patients with a diastolic pressure of 120 or over to stay in bed one day a week.

Dr. Herbert French informed me that he got excellent results by venesection, which the late Sir Clifford Allbutt also recommended. The withdrawal of about a pint of blood twice a year probably benefits plethoric patients, but in thin delicate individuals it is contra-indicated.

Depressor drugs have merely a transient effect, but a chemical agent that will adsorb putrefactive bases from the alimentary tract may prove successful. If the systolic blood pressure is over 200 mm. Hg it is as a rule advisable to give erythroltetranitrate for several days before beginning hydrotherapeutic measures. It has already been stated that any form of excitement may tend to put up the pressure considerably, and there is a certain amount of apprehensive tension associated with bathing procedures that the patient has not hitherto experienced; hence the desirability of prescribing a drug which will lower the blood pressure before subjecting the patient to a new form of treatment that may have an exciting effect.

Quite recently I have tried animasa tablets, with encouraging results. In two cases neither waters nor baths were used, and the result was a moderate reduction in pressure. In other cases I gave the tablets when the patients were having Plombières douches or electric massage, and it seemed to me that the reduction in blood pressure became more marked.

AN OUTBREAK OF PARATYPHOID B FEVER.

By Iris V. I. Ward, M.B., B.S. Lond.,
HOUSE SURGEON, WEST HERTS HOSPITAL, HEMEL HEMPSTEAD.

In a recent paratyphoid B epidemic in West Hertfordshire 140 cases were notified. The source of infection was traced through a dairy to a small farm where a child, aged 3½ years, supposedly ill from broncho-pneumonia for some time, was found to have a strongly positive Widal reaction to paratyphoid B. Her mother, who handled the milk, had a positive Widal and paratyphoid B bacilli were isolated from the stools. She denied any illness and affirmed that her health was as usual except for a painful, red, œdematous swelling of the left breast. The swelling was aspirated and thick creamy sterile pus was withdrawn. She gave a history of recurrent discharge from the left nipple during menstruation, although the nipple was healthy and lactation had not occurred for three years. The infected milk was, apparently, sent in churns to a large distributing dairy and thereafter supplied to two districts which suffered heavily. The greater area supplied by the same dairy practically escaped infection.

On Saturday, Nov. 12th, the West Herts Hospital admitted 23 cases. The total accommodation normally is 108 beds and of these only five were available. A detached wing ward was emptied and prepared for the reception of 40 patients. The male and female ends of the ward were put in charge of staff nurses and the whole unit was run as a separate hospital section in charge of the ward sister. By the 16th 42 cases had been admitted; their ages ranged from 6 weeks to 47 years.

Children (23 cases).—Aged 6 weeks: 1 female; aged 1¼ to 4 years: 10 females, 7 males; aged 8 to 14 years: 1 female, 4 males.

Adults (19 cases).—Aged 15 to 47 years: 11 females, 8 males. None of these cases had been inoculated.

Incubation Period.—On one occasion only the incubation period was definitely established as ten days.

An infection of great interest is that of the baby, aged 6 weeks.

Mrs. H., on Oct. 21st, gave birth to a full-term healthy female child. The puerperium was uneventful until Nov. 2nd, when the evening temperature was 99° F. Next day the temperature rose gradually to 101° at 2 P.M. and 103° at 6 P.M. On the 5th the temperature was 105° and breast-feeding was discontinued, but the baby was not removed from the mother. On the 10th a diagnosis of paratyphoid fever was made and the mother was isolated. On the 30th the baby became ill with a rise of temperature and bronchitis, followed in a few days by a fairly profuse and typical rash. This was 20 days after isolation from the mother and 25 days after the cessation of breast feeding.

The important points about the case are: (1) the age of the child; (2) the fact that it was breast-fed for three days during the septicæmic stage of paratyphoid fever without contracting the disease from this source.

Onset.—In adults, on the whole, the onset was insidious with headache, epistaxis, abdominal discomfort, and diarrhœa. Headache was severe in adults, lasting about one week. In children the onset was more sudden with abdominal pain, high fever, and diarrhœa. One child, previously well, ran in from play screaming. For the next few days she had short periods of blindness, and on admission lay curled up on her left side with slight head retraction, resenting all interference—a typical picture of cerebral irritation. Another child, an epileptic, not included in the series, started the disease with an epileptiform convulsion. Epistaxis was fairly common as an initial symptom among adults. One boy, aged 14, had a severe epistaxis. Vomiting was not a prominent symptom either at onset or during the course of the disease. Delirium occurred in one case only. Catarrh was common as an initial symptom. One of the earliest cases started with signs of congestion at the left base. Two boys had irritating coughs, but no signs in the chest.

Rash appeared about the tenth day and was very profuse on chest, abdomen, flanks, and arms and legs, and in one case on the neck. Successive crops of spots appeared over a period of seven to ten days. Rash was particularly profuse in children.

Progress.

Temperature very high and swinging, particularly in children, in whom it commonly varied between 103° and 104° in the evening and 98° or 99° in the morning and persisted for a week to ten days. Fall of temperature occurred by lysis in majority of cases at end of third week.

Toxicity was extreme in children.

Bowels.—After the initial diarrhœa, which lasted a few days, constipation was the rule except in five children and two adults. In the children the stools were green—not the characteristic "pea soup" stools of typhoid. Sloughs were found in the stools in one case only—that of a child of 2½ years.

Complications.—Chiefly respiratory. Broncho-pneumonia in three children. One boy, who started the illness with congestion at the left base, developed a severe and persistent bronchitis. There were boils and abscesses on head and buttocks in two children. Myalgia: In intercostal and abdominal mucles in one boy. Acute gangrenous appendicitis: One man admitted with history of shivering, abdominal pain, headache and backache for five days. Temperature 102°; pulse-rate, 96; respirations, 24. Extreme tenderness and rigidity in left iliac fossa. Operation same night; gangrenous appendix removed. Temperature remains high (102°) for following three days. Abdomen satisfactory. On fourth day after operation a profuse rash appeared on abdomen and Widal was positive to paratyphoid B. Further progress was uneventful. Acute gangrenous appendicitis has been known to occur before as a complication of typhoid fever.

Acute nephritis.—Male, aged 34, was taken ill on Nov. 9th and admitted to hospital on Nov. 23rd with a typical ras Temperature was normal. Progress was satisfactory un Dec. 3rd, 1927 (twenty-fourth day of disease) whe temperature rose suddenly to 101·2° and was accompani by headache, hæmaturia, and albuminuria. There w no œdema. The daily output of urine was ℥ xv. on average and *B. paratyphosus* B were cultivated from t urine on Dec. 6th. Temperature remained high and ran typical typhoid course for three weeks. Hæmatur persisted for one week. The urine was negative *B. Paratyphosus* B on Jan. 5th, 1928. There was still slig albuminuria on discharge on Jan. 7th. Perforation: Non Intestinal hæmorrhage: Occurred on two occasions at t end of the second and beginning of the third weeks of illne in a child aged 2½ years. It was fairly profuse, but yielde to treatment readily. There were no sequelæ or relapses

Notes on Carriers.

Of those who actually had the disease, one woma who started a moderately severe attack on Nov. 1s is still passing paratyphoid bacilli in her stools i.e., 12 weeks after the onset. Intestinal antisepti have been of no avail.

A very disquieting feature of the epidemic was th routine examination of the roundsmen at the dai showed that six, apparently well, were carrier paratyphosus B were cultivated from their stools an on one or two occasions, from the urine. It is inco ceivable that these six men, the majority of the dai staff, could have been carriers prior to the epidem and we may safely presume that they became carrie by infection from the milk which they handled a drank. We may further presume that many in t district who did not show clinical signs of the disea were also infected and were potential carriers. would be irksome and very costly for the heal authorities to examine all the men, women, a children who had drunk infected milk and to ascerta whether they were carriers or not. Amongst thc who have clinically developed the disease the carri can be recognised, but of the vast number who ha been infected and have either not developed the dise or have had a mild unrecognised attack nothi whatever can be known.

Would it not be better, therefore, to protect community by widespread inoculation, either by t subcutaneous method (which in this case would impracticable and very expensive), or by Besredk method of oral administration of vaccine? Bo these methods have proved effective in the armi The latter method is easy, effective, and practica in a situation such as this. The expense is trivi In Africa the natives have been protected in t way at a cost of 4*d.* per head. Carriers cannot prevented and often cannot be cured. Much pub money is spent in trying to deal with the probl indirectly that ought to do much to rid our coun of enteric if spent in immunisation of districts wh that disease sporadically recurs.

I am indebted to the honorary staff of the W Herts Hospital and to the medical officer of hea for Hemel Hempstead for permission to publish th cases.

A CASE OF EARLY TROPICAL ELEPHANTIASIS TREATI BY PROTEIN SHOCK.

By W. E. Cooke, F.R.C.S. Irel., D.P.H.,
MEDICAL SUPERINTENDENT, HOSPITAL FOR TROPICAL DISEASES, LONDON.

The geographical distribution of the *Filaria bancrofti* corresponds with that of tropical elephantia Other arguments can be advanced to show that elephantiasis follows the filarial infection, and absence of microfilariæ from the blood stream patients who exhibit elephantoid deformities is n accepted as usual and does not rule out the fila origin of the disease. The factors leading to elephantoid changes in the tissues are not definit

known, but most authorities are agreed that in addition to lymphatic obstruction bacterial infection is necessary.

The treatment of elephantiasis is not satisfactory and is dependent mainly on the region implicated. Rest, elevation and support of the parts, massage, vaccines, light, and surgery all have to be tried, and often the condition continues to advance despite all these means. Preventive measures must be directed against the preliminary filariasis, for which unfortunately no effective treatment has yet been evolved. Recognising the success attending "protein shock" treatment in other tropical diseases where bacterial infection is present, and accepting the probable contributory bacterial factor in elephantiasis, I determined to try this mode of treatment on the next favourable case arriving in hospital.

The Case Related.

The patient was 26 years of age and was born in India of white parents. At the age of 18 she came to England for three years, then returned to India till 1927, when she again came to England. Previous illnesses: measles, tonsils and adenoids stated to have been removed in childhood, malaria, mumps, influenzal pneumonia, diphtheria, and dengue.

During the voyage home her right leg became red, painful, and swollen. There was no history of injury. The ship's surgeon treated it with fomentations and rest, and some improvement took place, but walking at Port Said caused a relapse, the swelling increasing and appearing above the knee. The limb was also painful to touch.

On arrival at the Hospital for Tropical Diseases on Feb. 11th, 1927, she was admitted at once. The right leg was then swollen below the knee, one area on the lateral aspect of the middle third of the limb being more hyperæmic, and definitely tender to the touch. Right ankle measured 8½ in. and left ankle 8¼ in. Groin glands on both sides were enlarged and the right iliac glands were palpable and tender on pressure. Chest, heart, liver, and spleen were normal. Both tonsils were slightly enlarged and the left showed some cheesy exudate in the crypts. Temperature, pulse, and respiration were normal. Blood count was as follows: red cells, 5,000,000; white cells, 10,000; hæmoglobin, 90 per cent.; polymorphonuclears, 51 per cent.; lymphocytes, 33 per cent.; large mononuclears, 6 per cent.; eosinophils 10 per cent.; parasites, nil. Wassermann was negative. No microfilariæ were found at any time in the blood.

The series of stools examined was negative for ova or protozoa. Urine (catheter specimen) was normal. Menstruation regular with occasional dysmenorrhœa.

Taking into consideration the history of residence in a filarial district (Madras), the adenitis of the groin and iliac glands, the history of onset, and the 10 per cent. eosinophilia, the diagnosis reached was that of commencing elephantiasis of the leg. With the usual treatment of rest, elevation, and massage, the swelling gradually subsided and the tenderness passed away.

The patient was very much distressed when informed of the future outlook in her case as she had seen the condition frequently in India. She therefore readily consented to undergo the "protein shock" treatment in the hope that it might obviate or retard the usual progressive nature of the complaint. After a fortnight's preliminary treatment a series of four "shocks" were given, T.A.B. vaccine being used.

Feb. 25th, 1927: 50 millions T.A.B. given intravenously. Headache and vomiting with slight pain in the right iliac and groin glands followed. Temperature rose to 103·4° F. Throat felt sore. March 6th: 100 millions T.A.B. given. Temperature rose to 101·8. Headache and vomiting recurred. March 12th: 200 millions T.A.B. given. Temperature rose to 101·2°. Headache and vomiting again occurred. March 19th: 250 millions T.A.B. given. Temperature rose to 101·8 °.

Between the "shocks" the patient was permitted to walk about. On March 15th the measurement of the right ankle was 8¼ in., the left 8⅛ in., a reduction of 1 in. since admission.

The patient was discharged from hospital on March 25th, looking and feeling well. All pain in the glands had subsided. She had been provided with an elastic stocking, and in it the ankle measurements then read: right, 8¼ in.; left 8 in.

I saw her again in May. In the meantime she had had tonsillectomy performed. The leg was quite satisfactory with no sign of swelling, and she was still wearing the stocking. Visiting in August, she stated she had been working hard and taking plenty of exercise, but there was still no sign of swelling in the leg. In her last report, written on Nov. 20th from India, she stated that she was travelling constantly as her work demanded, that in consequence she had little opportunity to follow directions as regards rest, &c., that the limb had shown no signs of swelling and when measured was no larger than the other though she had occasionally dispensed with the stocking, and that she felt very well in every way.

Comment.

The condition of pseudo-elephantiasis seen in this country has sometimes been attributed to tonsillar infection, and is reported in some instances to have shown improvement after proper throat treatment. The throat condition may have been a contributory factor in this case, but it does not account for the adenitis of the groin and iliac glands, or for the eosinophilia. These definitely point to an antecedent filarial infection. It is much too soon yet to say that permanent good has resulted in this case, but, in the hope that others, with more opportunities, may carry out "protein shock" treatment in early cases of elephantiasis and report their results, I venture to publish this case.

My thanks are due to Dr. G. Carmichael Low for permission to give this treatment to his patient.

A CASE OF
ACUTE STAPHYLOCOCCAL PYÆMIA.

By S. Deaner, M.R.C.S. Eng.,
HOUSE SURGEON, KING EDWARD MEMORIAL HOSPITAL, EALING.

An acute pyæmia caused by infection with *Staphylococcus pyogenes aureus* is uncommon in these post-war days and the symptoms presented in the following case render it worth recording.

On Jan. 21st, 1928, the patient, a man aged 28, developed a carbuncle on his right arm which became very œdematous. A week later he was suddenly seized with a rigor, followed by acute pain in the left side of his chest and abdomen. He immediately developed a most distressing cough, bringing up blood-stained sputum. Simultaneously he had hæmaturia and frequency of micturition.

He was admitted into hospital next day. His condition then was: temperature, 103° F.; pulse-rate, 112; respirations, 48; orthopnœa. Impaired note apex of right lung. Pleural rub left side. Extreme tenderness and rigidity both loins. The urine contained blood and pus. The carbuncle was incised and the *Staphylococcus aureus* was obtained in pure culture from the carbuncle, urine, and blood, and was the predominating organism in the sputum.

On Feb. 1st there was sudden painful swelling of the right testicle. The hæmaturia had now ceased, but pus was still present. On Feb. 3rd a parotid abscess appeared on the right side of the face. This was incised. Purpuric spots appeared and the patient became slightly jaundiced. Although the arm was much better and the patient apparently more comfortable, the jaundice and purpura became more marked until on the 7th there was a sudden attack of dyspnœa and he died.

Unfortunately we did not obtain leave for post-mortem examination, but the case was undoubtedly a staphylococcal pyæmia with metastases especially in the lungs and kidneys. The patient had an autogenous vaccine and intramuscular injections of manganese butyrate as well as treatment for the local symptoms, but the infection was too severe.

I am grateful to Dr. R. P. Cockburn for permission to publish this case.

Death of Dr. T. H. Morris.—The death occurred at Cardiff on Jan. 24th, at the age of 72, of Thomas Henry Morris, M.B., C.M. Glasg., who for over 30 years had been a prominent figure in the public life of Glamorgan. He had been practising in the Rhondda Valley for 36 years, and represented the Tylorstown division on the county council until he became alderman. He was for many years chairman of the Finance Committee, and was made a justice of the peace in 1914. He was a fluent speaker of Welsh, and a great patron of Welsh literature. He is survived by his second wife and by the two daughters of his first marriage

Medical Societies.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society on Feb. 13th Mr. HERBERT W. CARSON, the President, occupied the chair, and a discussion was held on the

USE AND ABUSE OF ULTRA-VIOLET LIGHT THERAPY.

Dr. LEONARD HILL, in opening the discussion, first referred to the well-known physical properties of the various kinds of rays which had been investigated, including infra-red and wireless waves. He said that, in respect of waves applied to the human body, two things had to be considered—the biological power to cause a chemical change when absorbed, and the power of penetration. The modern evidence which had been adduced was that the ultra-violet rays attacked the atom and its gyrating electrons and displaced some of those electrons from their orbits, this displacement occurring when the rays were absorbed. The resultant chemical and molecular change was slow; in the case of the human being there was a latent period, and the erythema did not supervene until some hours after the exposure to the rays in question. When the action of the rays on infusoria was watched under the microscope, the living matter could be seen to be gradually coagulating as the animal died. The long ultra-violet rays, of from 4000 to 3000 A.U., were, he said, not greatly absorbed by living tissue; they passed through like visible rays, and reached the blood-vessels below the epidermis. The middle length ultra-violet rays had very little power of penetration, they were largely absorbed by the horny layer of the epidermis, and very few of them reached the blood-vessels beneath. Nevertheless, they would penetrate and kill a bacterium or infusoria. Very short ultra-violet rays could not penetrate more than one bacterium. Rays shorter than 2500 units did not come into the sphere of human effect. It had been shown, by some beautiful experiments, that the rays which had the maximum erythema power were those of 2970 units, that of the sun's rays when it was high in the heavens on a clear day; those rays were specially active in producing vitamin D. Cells which were killed by the rays coagulated, and in this way a protection was set up in the surface cells and the horny layer was thickened. For that reason the burn produced by ultra-violet rays was never deep. Blistering and œdema could occur as a secondary consequence, and in a weakly patient there might be fever and a feeling of illness, but no approach to fatal results was likely. The rays certainly provoked the defensive power of the body. He regarded the skin as the great natural organ of defence against microbic infection, able to maintain its tone and to react in various conditions of temperature and degrees of exposure. There was no better method of stimulating this action of the skin than by the application of ultra-violet rays, as they could be applied to any given area and in any desired dosage. These rays certainly increased the skin's bactericidal power. If, however, the rays were used in doses too big, or over too wide an area, this bactericidal power in the skin was reduced and harm resulted. In the same way people could feel exhausted and become nervous by being too long exposed to sunshine in the tropics. He pleaded for more open-air hospital treatment, as this was a natural corollary of the advances in knowledge concerning actino-therapy.

Treatment of Lupus.

Dr. W. J. O'DONOVAN said that the presentation of clinical results in a rigid statistical form was usually misleading. No two patients with the same diagnosis formed exactly the same clinical problem; differences of sex, age, duration, and intensity must come into the picture. The test of value of light therapy was the fact that it was retained in the physician's armamentarium; it had been continuously carrie out at the London Hospital since 1900, and the numbe of practitioners using it was always on the increas He did not agree that large areas of lupus wer incurable, though they certainly needed prolonge treatment. He contended that surgeons unknowingl produced lupus by operations for glands in the neck he recognised it coming weeks or months after th operation as a sort of apple-jelly infiltration, to whic he gave the name "chin-strap lupus." This could b prevented by giving a routine course of light therap after neck-gland operations. He now had 200 suc cases under treatment. For lupus the light therap must be both general and local, as the destruction c the tubercle bacilli was slow. He declared that light treatment had only served to banish X ray from the therapeutic field of lupus, it would hav amply justified its existence, for, although th immediate results of X rays were often gratifyin later results not only included scars but sometime warty and epitheliomatous metaplasia. For lupu erythematosus, however, light therapy was a waste c time and effort; and he was discouraged by its effec in acne. Psoriasis was of many forms, and or treatment could not be expected to be good for al But in widespread cases he had completely cleare the lesions and obtained two years of freedom fro relapse by a steady daily dosage of ultra-violet ligl from the mercury-vapour lamp, and also by the carbo arc lamp. He combined the treatment with vigorou inunctions of ointment. Actinotherapy was mo valuable in combating pruriginous conditions, thoug it was his strong belief that many of the cases we of psychic origin. Ultra-violet rays have been reporte to cure ringworm, but the small penetrative power these rays did not seem likely to deal with an infectio well below the surface of the skin of the scal Eczema was not a disease, but was a reaction various external irritants. Herpes zoster in patien over 55 years of age, especially the intense pain aft the lesions had scarred over, had not hitherto yielde well, but daily local ultra-violet baths had afforde relief. The same course was of great benefit aft operation for carbuncle, as it hastened convalescen and the coaptation of the edges of the wound. H urged the avoidance of clinical literature written b professed actinotherapeutists, as the optimism such people, unsupported by a large mass of medic experience, was apt to beget unbounded and dangero optimism.

Abuses of Light Therapy.

Dr. C. B. HEALD divided the abuses of ultr violet light therapy into three categories: (1) extrav gant claims, (2) injudicious dosage, (3) home us which had been referred to a good deal in the l press. The first of these he regarded as the greate abuse of all. To claim cures of cases unsupported b scientific measurement or accurate clinical data a based on insufficient numbers was dangerous, m leading, and liable to bring the subject into disrepu Recently claims had been put forward that varico ulcers uniformly yielded to, and could be cured b ultra-violet light. His colleague, Dr. Dora Colebroo who had been working with him at the Royal Fre had treated cases of the condition supplied by I Haldin-Davis, following the exact technique of t man who made the claim, and watching the cas carefully, but there had been complete failu A report on 47 cases treated by another meth would, however, shortly be published. Wrong dosa implied failure to realise the true needs of the patie Treatment could be divided into sedative—includi rest in bed—tonic and, in certain cases, count irritant treatment. The first preliminary was, sure accurate diagnosis, not only of the disease, but the general condition of the patient. Only a kno ledge of the lamp and what it was capable of and wh it was desired to reach with that lamp could lead a proper dosage of rays. In 1922, when less w known on the subject, a man who had had phthis which was at that time quiescent, came because had strained his back by using a pick in a pecul

way. Dr. Heald had decided to give him a counter-rritant dose of ultra-violet light and there was no question that this resulted in a lighting up of his phthisis, and he went through a long and serious illness before he recovered. Ultra-violet light could produce cataract, and it could cause an increase of bacterial infection. In a case of chronic long-standing arthritis of the right hip after a hunting accident, when the patient had made considerable progress under diathermy, the speaker gave him ultra-violet light, the immediate effect of which was to precipitate an acute attack of appendicitis within six hours. He had seen healthy persons converted by these rays into light-sensitive patients.

Dr. Heald did not join in the universal condemnation of the home use of the lamp, neither did he recommend its universal adoption. When well administered, ultra-violet light could alter the lime salts in bone in a short time; it healed over burns rapidly, and modified the nutritive value of the milk of nursing mothers. As, however, the rays could also set up or reawaken phthisis, it was a therapeutic means which could not be thoughtlessly set up in every home. Nevertheless, armed by a set of instructions to meet certain conditions, in the same way as any other prescription was used, there was a considerable sphere for the home use of the rays. In reports of alleged cures there was too often a total lack of essential data, such as the means employed, the time or frequency, and the distance of the lamp from the lesion. There was still need for careful control experiments.

At the Royal Free Hospital a good deal of work had been done with the rays in ununited fractures. In the last five years 4011 fractures had passed through his department, and in no single case had there been failure to bring about union, although cases of delayed union had been sent from infirmaries and other places.

Discussion.

Dr. H. HALDIN-DAVIS agreed that ultra-violet light was practically inert in cases of varicose ulcer.

Dr. D. M. BARCROFT said he believed ultra-violet light was often administered when it was found that no medicine brought benefit. He had succeeded in curing Vincent's angina with the rays in one case. He had found them distinctly disappointing in acne, though there was benefit for a time. He did not think ultra-violet light cured anything, but it postponed relapses, fortified patients and thus enabled them to put up a better fight against disease.

Dr. A. C. ROXBURGH spoke of the value of ultra-violet light for the detection of ringworm of the scalp. A patient was taken into the dark room and stood under the mercury-vapour lamp with the hood closed and its opening covered with Wood's glass, which cut off practically all visible light. Under this light the ordinary hairs looked as if they had been lightly dusted with flour, but ringworm-bearing hairs shone with a greenish iridescence. This not only enabled detection to be quickly carried out, but treatment could be restricted to the exact area required.

Dr. G. VILVANDRE referred to the danger of arriving at hasty conclusions. He averred that the experiments which were carried out on the change in the bactericidal power of the blood caused by the rays were too few to be of value; they should be repeated on a larger scale by many observers. A patient might be in a serious condition and ultra-violet rays might not improve the general health that serious disease, such as carcinoma, might not be suspected. He noted such a case, which eventually died of the carcinoma. Before applying either ultra-violet rays or X rays it was very important to make a firm diagnosis.

Mr. ZACHARY COPE regretted that there were not at available scientific means of measuring the dosage required and given for certain set conditions. The subject was important enough for a committee to investigate and set up standards of dosage.

Dr. LEONARD HILL, in reply, said that the final standards of dose must be biological, and it was easy in the case of a given patient to place round him a belt into which windows were cut and to give 10 or 15 minutes' exposure, noting the degree of erythema. The acetone-blue method was quite accurate for the lamps, and it enabled the operator to ascertain whether his lamp was keeping up to the required efficiency. In reference to what Dr. Vilvandre had said, the work on the bactericidal power of the blood had been done on a large series of animals.

ROYAL SOCIETY OF MEDICINE.

WAR SECTION.

AT a meeting of this Section held on Feb. 11th, Surgeon Vice-Admiral A. GASKELL, the President, being in the chair, Surgeon-Commander S. F. DUDLEY discussed the

Epidemiology of Typhoid Fever in the Royal Navy.

He described three epidemics in the first of which there were 97 cases in a ship of some 1000 men, the 70 officers wholly escaping infection. In the search for the cause water, fried fish, infection ashore, and a carrier, were all excluded, and it became evident that the epidemic was due to the issue of 500 lettuces from a forbidden source, to the men only, six days before the cases began. There were two maxima, the first, 12 days after the issue, the second and smaller a fortnight later. The cases were of a graduated severity; they included some men who had only two or three days' pyrexia, 13 who went back to duty in ten days, and a certain number who had intestinal hæmorrhage and perforation. Half the cases were mild and the total mortality was only seven, perhaps because the cases were all under medical—and the same medical—supervision, so that every one of them was counted, including those which might otherwise have escaped observation. Sixty-eight were treated in a military hospital, the rest on board; all gave positive Widal reactions, even 22 of the mild cases who had never been inoculated. About a third of the men had at some time been inoculated, but two-thirds of the mildest cases had not. The boys and ordinary seamen, who formed the youngest group, got off lightly, but they had all been inoculated within the preceding two months. The younger R.N.V.R. men, aged 18-20, suffered most, being the newest in that environment, whilst the oldest men, the chief petty officers, escaped entirely. When the epidemic was well advanced the whole ship's company was inoculated, but the cessation of cases thereafter was, the lecturer thought, due rather to increase of the herd-immunity than to the effects of inoculation. He had already[1] shown, he said, that infectious disease always attacks most heavily those groups with least experience of the environment; and so it was in this epidemic except for the protection conferred by inoculation. Age, he said, is not in itself important; it is the amount of bacterial experience that counts. In civil life ashore age and immunity generally advance equally, but in the service the bacterial environment is more dense and variable, and recruits are more likely to become infected than seasoned men. The story of a second smaller epidemic of food-borne typhoid was narrated, and an account was given of the many cases spread through ships by a carrier over a period of 16 years.

[1] Med. Res. Council Special Report, No. 75 (1923) and No. 111 (1927); THE LANCET, 1924, i., 1141.

ABERDEEN ROYAL INFIRMARY.—Figures presented to the annual meeting of this institution showed that the additional expenditure caused by increased demands had been counterbalanced by larger revenue. The cost per occupied bed has been reduced by £3 16*s.* 4*d.* At the annual meeting of the corporation of the Aberdeen Royal Mental Hospital, held at the same time, it was stated that the institution last year saved about £1500 by being exempted from income-tax.

ROYAL INSTITUTE OF PUBLIC HEALTH.

AT a meeting on Feb. 8th, at which Sir ERNEST WILD, Recorder of London, took the chair, a lecture was given by Dr. W. NORWOOD EAST on

PROBLEMS IN FORENSIC PSYCHIATRY.

He said that unfortunately, as the result of recent litigation, there seemed to be real danger that the interest of many practitioners in mental disorder might be withdrawn; thus early symptoms would pass unrecognised. A general practitioner might well hesitate to give expert evidence on mental issues, but he might effectively assist the administration of justice by relating his own observations, even if he did not feel justified in forming an opinion on them. The final decision of the expert might receive strong support from the facts observed by the general practitioner. It was essential for the medical witness to remember that the irresponsibility of an accused person was a question for the jury and not for the witness; that an accused person was held to be sane and responsible until proved to the contrary; that certifiable insanity and legal insanity were not coextensive; and that three different standards of insanity were accepted. In non-indictable offences the standard was usually that of certifiable insanity. In cases tried before juries insanity was considered in relation to the mental condition at the time of trial or of commission of the crime. A person found insane on arraignment was liable to be tried later should he recover sanity. The criterion of insanity known as the McNaghten ruling invited criticism and refuted amendment. It had been decided that the question of feeblemindedness should not be put to a jury as the question of insanity was, but the judge might and did consider it, and could send the prisoner to a suitable institution instead of to prison. The law made no provision for lesser degrees of mental alienation, such as psychopathic personalities, psychoneuroses or subnormal intelligence and social capacity, but the judge might modify a sentence on these grounds.

The medical witness had to decide the most difficult question of normality or abnormality, and must assess each individual in the light of his own knowledge and experience. Some doctors held that delinquency in itself indicated abnormality, but those who had studied and worked in daily contact with prisoners could not support this view. There was real danger, however, that it might be misconstrued into an excuse for anti-social conduct. A false suggestion of mental invalidism often aggravated misconduct, especially in young adults in full enjoyment of modern liberty while still physically and mentally immature. Doctors must bear in mind that motive was the reason for a particular course of action, and that intention was the desire to produce a particular result.

Senility and Crime.

Senility was an example of a normal mental state which passed by imperceptible degrees into the abnormal and occasionally thence into insanity. The quantitative reduction characteristic of senility was the mental inferiority of the individual as compared with his former self and not as compared with others. If senile patients became insane there might be qualitative alterations in addition: delusions, hallucinations, and periods of excitement or depression. The crimes of this period were mostly minor, such as vagrancy, begging, and drunkenness, but more serious offences, such as frauds, thefts, and sex offences occurred, and occasionally grave crimes such as murder were committed. There was no reason to consider an aged person abnormal merely because desire outlived virility and resulted in misconduct. In many cases sexual offences had little causal relation with age, although a pathological basis might be inferred when the subject had shown diminished control in ordinary affairs, or when there was a psychopathological climacteric change.

Epilepsy.

There was a general impression that epilepsy wa a common cause of crime, but in fact only 0·5 per cen of 9491 prisoners were epileptic, and even then th crime was not always attributable to the disease Unemployment resulting from fits might be th direct cause of crime, and the irritable epilepti temperament occasionally expressed itself in crime of violence. The grosser abnormal mental states du to epilepsy were automatism, excitement or furo and feeblemindedness. Automatism was a favourit criminal defence and satisfied the legal criterion o insanity, but epilepsy in itself conveyed no immunity Witnesses sometimes assumed automatism withou any evidence of epilepsy, which was essential, thoug difficult to obtain. Automatism might occur withou an antecedent fit, and was generally more conspicuou and prolonged after a minor than after a majo attack. An essential feature was loss of memor for acts and events during the automatic perio Some authorities seemed to think it possible tha the period merged gradually into normal consciou life, so that acts committed just before the perio ended were carried dimly into memory; this vie favoured the malingerer. The highest authorities, hov ever, and those with prison experience, thought tha the epileptic had no such memory, and the speake thought it would be unwise to admit that a crimina act could be the result of epilepsy if certain part culars of it were remembered by the accused. A automatic period did not necessarily follow every fi Automatic acts might vary at different times in th same subject, but were usually habitual acts or th caricature of such acts.

Epileptic automatism might be inferred when a epileptic subject exhibited purposeful conduct o which he had no memory, which lacked consciou motive or intention, which might be repeated in su cessive automatic periods, and which was usual of the nature of a habitual act or the caricature such an act. Epileptic excitement occasional resulted in crime; it might be intense, but wa usually transitory. The subject might be ful conscious of his acts. In epileptic feeblemindednes as in other forms of epilepsy, collateral eviden might be provided by moroseness, suspiciousnes querulousness, hostility, impulsiveness, or religio emotionalism.

Alcohol and Crime.

The medical witness must be careful not to confu alcoholic insanity with intoxication. The ment conditions in which alcohol was associated wi crime might be classified as acute, including drunke ness, mania-à-potu, and delirium tremens; and chroni such as alcoholic hallucinatory insanity, alcoho pseudo-paresis, pseudo-paranioa, and dementia. Wh an alcoholic was also epileptic acts committed duri intoxication might be so automatic as to be confus with epileptic automatism. The latter exculpat the accused, whereas automatism resulting fro intoxication was a voluntary condition produced b misconduct for which the individual was responsib An accurate diagnosis was therefore legally importan but might be extremely difficult, as convulsio might be due to alcohol or epilepsy. If the medic evidence were evenly balanced the witness shou content himself with testifying that the crime mig be due to either or both and must not weight the scal on either side. In mania-à-potu the subject co mitted acts of extreme violence over which he ha no control and of which he might have no recollectio If an epileptic indulged in alcohol, mania-à-po might be confused with epileptic furor. The ter "pathological drunkenness" was sometimes loose used; a special term should not be used if it on meant that some people were more susceptible tha others to alcohol on account of heredity, disease injury. Indeed, the technical phrase might false lead a jury to believe that the drunkenness was not voluntary act.

When an alleged crime was such that the intenti of the accused was one of its constituent element

ıe jury might consider the fact of intoxication. If e had been too drunk to form an intention, he might e convicted of a lesser offence into which intention id not enter. Insanity caused by intemperate habits ıight exempt an accused from responsibility. Mania--potu or delirium tremens practically amounted to ·gal insanity. The symptoms of chronic alcoholic ısanity varied in intensity according to the time ·hich had elapsed since drinking. Alcoholics might ave sufficient control when sober to hide any delu-ons or hallucinations, but expressed them freely ·hen temporarily under the influence of drink.

Uncontrollable Impulse.

Witnesses were not always prepared to distinguish etween an uncontrollable impulse and an impulse ·hich was not controlled. To avoid confusion, regard ıust be paid to the emotions accompanying the ıherited instincts which underlie human conduct. he instincts might act with too great or too little ›rce and the emotional expressions might be excess-ve or insufficient. Crime might result from the ›njunction of an over-dominant sex instinct with efective control and inadequate moral sentiment. imilarly the wealthy shoplifter might be suffering ·om a strong acquisitive instinct, of which she was ware, but nevertheless she flirted with temptation y attending sales. Faulty control was often asso-ated with crime, and occurred when the emotional ttitude accompanying instinctive action failed to ecome inhibited by the consideration of the probable ›nsequence, or when the conscious exercise of the ·ill was insufficiently opposed to the desire of the ıoment. Control depended upon the capacity to roduce sufficient conscious mental energy to inhibit esire and enable action to be based on formed ıdgment. Irresistible impulse might be very real, nd the sole indication of mental disorder, although ot recognised in itself as an answer to a criminal harge. The court might accept proved insanity as n explanation of the impulse. An irresistible impulse ad certain features which, taken together, distin-uished it from a criminal impulse which was con-·ollable but not controlled. It was recurrent, the ıbject throughout was consciously aware of all that ›ok place, and retained clear memory; he passed ırough severe mental conflict before giving way to ıe impulse, which was followed by a sense of relief, ccompanied by regret that the impulse remained nconquered. At the onset of the illness the impulse ·as resisted, and if crime resulted it seemed to be ıotiveless. The detected shop thief, on the other and, would complain of a sudden uncontrollable npulse never before experienced. In practice an ssumed defence of irresistible impulse was easily isposed of, for only a particularly well-informed ıalingerer could describe all its features.

Encephalitis Lethargica and Adolescent Instability.

Sleepy sickness conveyed no immunity from legal esponsibility, but the medical witness might be sked whether a particular crime was the result of a ast attack. If the intellect was impaired and the ıental age corresponded with the age of the accused ·hen he had had the attack, then there was some eason to attribute subsequent criminal conduct to he disease. 16·5 per cent. of a series of 72 persons ·ho committed crime after an attack of sleepy sick-ess were known to have committed crime before it. 'he disease attacked young people, and subsequent ıisconduct might be due to other causes, such as dolescent instability. Criminal conduct in young dults was often due to excessive and irregular evelopment of the instincts and emotions, and faulty ıhibition. When the resulting mental instability ·as pronounced the subjects were inconsistent and nreliable, passing rapidly from one instinct, emotion, r impulse to another, and usually belonging to the ggressive criminal type. They were easily mistaken or cases of dementia præcox or manic-depressive ısanity, and were sometimes certified as mental efectives. Many of them, however, became adjusted later. Medical evidence should be based upon accurate observations and reasoned deductions, and not upon assumptions which cannot be supported under cross-examination. If this rule were followed, medical evidence would be more reliable and opposing views between medical witnesses less pronounced.

The Assessment of Punishment.

The CHAIRMAN said that everybody must have the greatest sympathy for doctors called upon to certify people as insane, and he wondered they ever had the courage to certify anybody after the things which had happened. In the preface to Dr. East's book he had read that there were nine distinctive and antagonistic schools of psychology that must be reckoned with. The law had one school of psychology and not nine: a man was presumed to contemplate and intend the consequences of his act. Once the doctrine of uncontrollable impulse got into the law courts justice would be impossible. He hoped some day that murder in the second degree would be part of the criminal law of this country. It was essential that the medical witness should speak from personal knowledge and experience. In so many cases the wealthy person went to a doctor for the first time in order to get him as witness. It was most important that the medical and legal professions should see each other's point of view. In many cases the judges or magistrates were only too willing and thankful to receive the suggestions of a medical witness as to the treatment of a criminal. If there was one difficult task in life it was to assess punishment. The three professions—medicine, law, and religion—should work together, for they had the same object in view.

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on Feb. 1st, with Dr. J. GRAY CLEGG, the President, in the chair. A discussion on the

Ætiology of Chronic Arthritis

was opened by Dr. J. B. BURT, who protested against the theory that all chronic arthritis was caused by some focal sepsis. It was just as reasonable to say that there was only one cause of chronic arthritis as to say there was only one cause of heart disease. After referring to the possible parts played by trauma, vitamin-deficiency, and other factors, Dr. Burt devoted special attention to the distinctive clinical signs of arthritis due to endocrine deficiency. These, he said, occurred chiefly in women at the menopause, but were also seen in girls at puberty, in thyro-pituitary deficiency, and sometimes in men over 60 with osteo-arthritis of the hip.

Mr. HARRY PLATT agreed that there was a tendency to exaggerate the importance of focal sepsis as a primary ætiological factor in chronic arthritis as a whole. This question must still be considered sub judice. The bacteriological and histological examination of tissues removed in cases of osteo-arthritis of the hip had given conflicting results. Cultures made from osteophytes and from portions of the distorted head of the femur had, in his own experience, proved sterile. On the other hand, the histological changes in the thickened joint capsule resembled those seen in other forms of fibrous tissue lesion where a definite inflammatory or microbic basis was admitted. Discussing the influence of injury in causing certain types of chronic arthritis, Mr. Platt said that a pure traumatic arthritis without the intervention of other ætiological factors had long been recognised, and was seen to follow mal-union in fractures of the shafts of the leg bones, or fractures involving the ankle-joint itself. Another factor of great importance was static error or incongruity of joint surfaces. Mal-adaptation of joint surfaces was by no means uncommon, particularly in the hip-joint. This condition obviously could follow an injury, or a mild inflammatory attack. More interesting still was the joint incongruity due to congenital causes. In recent years the significance of

the minor congenital anomalies of the hip-joint had been much studied by Calot and others. Congenital subluxation of the hip was present in a fair proportion of otherwise normal individuals, whose hip-joints were inclined to react to conditions of strain or infection at various periods of life. Calot claimed that the affection known as pseudo-coxalgia was really an unrecognised subluxation; and that the osteo-arthritis of middle life represented superimposed changes in a hip already defective from birth. This sweeping dictum could not be accepted, but it was fair to state that hip-joints, in which there was incongruity of surfaces from the very beginning, became the seat of chronic arthritis in later life.

MANCHESTER PATHOLOGICAL SOCIETY.

A MEETING of this Society, held on Feb. 8th, with Mr. F. H. WESTMACOTT, the President, in the chair, was devoted to the subject of

High Blood Pressure.

Dr. CRIGHTON BRAMWELL, in a paper by himself and Dr. Reginald Ellis, referred to the difficulty of defining the upper normal limit of blood pressure. As with many other physical attributes, he said, the range of variation followed the ordinary type of normal frequency curve. He did not regard a systolic reading of 150 mm. of mercury as necessarily pathological even in young people. There was little tendency for the systolic pressure to rise between the ages of 20 and 40, and even in healthy old people a systolic reading of under 150 was common. The high pulse pressure of old age was a compensatory mechanism to overcome the loss of elasticity in the arteries. Even apart from any structural change, the elasticity of the arterial walls might be greatly impaired by a high diastolic pressure; hence a relatively small rise in diastolic pressure would entail a much greater rise in pulse pressure if the heart was to maintain its output. In this respect a high diastolic pressure was just as important as a stiffened arterial wall in determining exercise-tolerance. The sphygmogram of hyperpiesis resembled that of aortic stenosis, the maximal pressure in the aorta being attained relatively late in systole. With regard to prognosis in these cases, Dr. Bramwell pointed out that the condition of the kidneys was of the first importance. In primary hyperpiesia, though the pressure might be higher, the outlook was not quite so grave as in the renal cases, in which the age-incidence was lower and which generally ended in uræmia. The diastolic pressure was of special significance in relation to the ultimate prognosis, since it represented the liability which the heart was called upon to undertake. The systolic pressure, on the other hand, was more closely related to the immediate issue, since it indicated the capacity of the heart to meet its liabilities. A falling systolic associated with a rising diastolic pressure was always a very bad omen, since it signified heart failure.

Prof. J. SHAW DUNN said that an account of the morbid anatomy of persistent hypertonus might still very well start with a reference to the long-established fact that chronic nephritis, primarily a disease of the kidneys, commonly produced a high blood pressure. The available evidence, including the temporary rise of pressure in acute nephritis, pointed to the circulatory change being a reaction to impairment of excretory function. It might be that some potent but hitherto unrecognised pressor substance was retained in the body owing to impaired excretion and so acted in excess on the vessels; another explanation, no less likely, was that in accordance with Cushny's view, all excretory substances were eliminated from the blood stream by filtration under pressure of the blood, and that where the field of filtration was limited a greater pressure was required to secure adequate elimination. In the more mysterious group of non-renal cases, or essential hypertonus, many of the morbid changes in the organs were of secondary character and of late developmen These were degenerative phenomena, such as cerebr hæmorrhage and cerebral softenings, atheroma arteries and shrinkage of the kidneys. Local softe ings and patches of atrophy of tissue seemed depend at times on the blood pressure, though hig being inadequate to perfuse some of the vesse whose contraction had helped in raising it. The degenerative changes varied markedly in degree they appeared to be most marked where deat occurred from cerebral hæmorrhage. In other case forming a smaller group, where death was due failure of cardiac compensation, the arteries oft had healthy intimas and the kidneys were smoo and of normal size or larger. The structural chang which might be said to occur in all cases of essenti hypertonus, or at any rate were found post morte in even the earliest cases, were (1) hypertrophy the left ventricle of the heart; (2) hypertrophy of t middle coats of the arteries generally—this was, his experience, invariably accompanied by sor fibrosis of the media, a degenerative feature, but earlier stage of pure hypertrophy might be presume (3) changes in minute arterioles of the size of t afferents to renal glomeruli. An affected ves showed thickening with fatty degeneration of i intimal coat, starting exactly at its origin from t parent trunk and extending throughout its lengt From its distribution and character this lesi hardly suggested the action of a toxin in the ordina sense; if such a toxin was at work it was difficu to see why the parent vessel should escape dama so completely as it often did. It seemed on t whole more likely to be due to a poor blood-supp in the smaller vessel, resulting from contraction the larger one. If this explanation of this chan could be supposed to hold good then all the earli structural changes in hypertonus were mostly eviden of the mechanism for maintaining it or of defec arising from the operation of that mechanism; t ultimate causal agency remained quite obscure. this agency was an abnormal pressor substance had still to be demonstrated. Other possibilit might be imagined on lines of analogy with chro nephritis—e.g., the presence in the blood of a su stance of low solubility which demanded excessi filtration for its elimination even by normal kidney lead and perhaps uric acid might suggest this type action. Increased osmotic pressure of the blo colloids would also demand a greater filtrati pressure.

Mr. GEOFFREY JEFFERSON dealt with blood pressu readings in the course of operations, especially ope tions on the central nervous system. The systo blood pressure and the pulse-rate were charted eve five, or in some cases, ten minutes regularly and t curves so obtained gave valuable information as the condition of the patient and some indication, any stage, of his capacity to undergo prolongation the operation. In more than one instance patie whose systolic pressure had fallen as low as 45 50 mm. of mercury had made uneventful recoveri

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of this Institution held on Feb. 2 Mr. K. W. MONSARRAT read a paper on the

Surgical Treatment of Diverticulitis.

After referring to the figures for the distribut of diverticulosis and of diverticulitis in the co given by E. I. Spriggs and O. A. Marxer,[1] he poin out that the conditions in which the disease w clinically evident could be described under fe headings: acute and chronic diverticulitis with complication, acute and chronic perforative dive culitis, and diverticulitis associated with steno In acute diverticulitis without complication n surgical treatment was, in his opinion, desira

[1] THE LANCET, 1927, i., 1067

whilst patients suffering from chronic diverticulitis ould be kept in health if they would submit to egular medical treatment. Acute perforation of a iverticulum should be treated on ordinary surgical rinciples, but in chronic perforation surgical treat-ient should be limited to opening and draining bscesses. When diverticulitis was associated with tenosis resection of the affected bowel was the peration of choice, but was only likely to be possible n a minority of cases, being often prevented by the ituation of the stenosis or by the extent of the isease in the bowel. The alternatives to resection ere short-circuit and colostomy. Among the 8 cases which he described he had had one in which olostomy was followed by subsidence of the disease nd disappearance of the stenosis, a second in which patient had remained well after a short-circuit peration, and a third in which successful resection as done.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Feb. 1st, ith Dr. A. LOGAN TURNER, the President, in the hair.

Dr. TORRANCE THOMSON read a communication on

Anæsthesia in High Abdomen Operations.

He stated that the chief difficulty was to provide dequate relaxation and at the same time to safe-uard the interests of the patient. This difficulty rose because stimulation of this area tended to set p glottic spasm and so to arouse special efforts on he part of the respiratory muscles. Atropine was ssential if ether was used. Morphia was generally iven in combination with atropine or scopolamine. Morphia might dull the respiratory centre, and scopola-ine occasionally greatly reduced the respiratory rate, o that there might be some difficulty in introducing fficient concentration of ether, and, moreover, here might be risk of suboxygenation, a very serious natter in the immediate post-operative hours. Both these drawbacks might be countered by the dicious use of oxygen and carbon dioxide.

For general anæsthesia alone nitrous oxide and xygen would not suffice to produce relaxation. t was not justifiable to depend on chloroform for he deep anæsthesia required in the initial stages of he operation, therefore ether was the agent of hoice. Ordinary inhalation anæsthesia might suffice, ut intratracheal insufflation of ether provided the est operation facility. The advantages of this ethod were that the anæsthetist controlled respira-on so that the diaphragm and muscles of the bdominal wall were not called upon to make special forts and that, as long as circulation was satis-actory, the depth of anæsthesia could be rapidly hanged if necessary. If an oxygen cylinder were sed to produce the air-current, oxygenation was erfect, the respiratory centre was not stimulated, nd everything conduced to the "silent belly" eloved of the surgeon.

Colonic oil-ether anæsthesia was deserving of a ore extensive trial in abdominal operations than it ad yet received. Local anæsthesia was generally rried out by the surgeon.

Regional Anæsthesia.

Dr. Thomson could speak from an experience of 00 cases of splanchnic anæsthesia carried out in llaboration with Prof. J. Fraser in his wards at the oyal Infirmary, Edinburgh. Careful notes had en taken of the condition of patients before, during, nd after operation. Blood pressure and pulse-rate cords were kept and operation facility noted. appis's method, introduced into this country y Hillman, was used. Light general anæsthesia as induced after the injection and the patient was ept asleep and, if necessary, anæsthesia was eepened. All high abdomen cases were for a time bmitted to the method. In a few patients abdominal field-block was carried out without the posterior injection being made; this was done for purposes of comparison. The conclusions reached were that the patients tolerated the operations well, their after-histories being very satisfactory. Shock had seldom been marked during the operation and in all cases had been quickly recovered from. None of the fatal cases had died of shock and there was no evidence that the anæsthesia had played any part in producing a fatal issue. There had been no post-operative respiratory complications. The impression received was that vomiting was less marked. The operation facility was on the whole good, but could not, in the speaker's opinion, compare with that attained under intratracheal insufflation of ether. It was important to note that these patients received, in addition to the splanchnic injection (1) preliminary morphine-scopolamine medication, (2) abdominal field-block, and (3) light general anæsthesia.

The success attending the few control cases, in which the same technique had been carried out with the exception of the splanchnic injection, suggested caution in expressing any very definite opinion on the value of the splanchnic method.

Discussion.

Prof. JOHN FRASER agreed that there should be the greatest coöperation between surgeon and anæsthetist. Although thoroughly impressed by intratracheal anæsthesia, he thought that with chloroform the greatest possible muscular relaxation was obtained. With pre-operative purging and starvation pressed to its usual extent, it was not surprising that gastric disturbance should follow.

Prof. D. WILKIE, though in most cases employing ordinary chloroform and ether, had for 12 years used field-block anæsthesia with general anæsthesia with excellent results. Spinal anæsthesia with scopolamine and morphia, field-block, gas and oxygen, he thought, had no unusual dangers.

Dr. F. G. GIBBS discussed the relative advantages and disadvantages in the use of scopolamine, morphia, and atropine. He did not care much for the intricacies of the apparatus for intratracheal anæsthesia.

Dr. JAMES YOUNG spoke of the advantages of spinal anæsthesia in Cæsarean section; it had a hæmostatic action on the uterus.

Mr. J. W. STRUTHERS, Mr. D. S. MIDDLETON, and Dr. A. GOODALL also spoke.

Pneumonia in Childhood.

A clinical and pathological demonstration on this subject was given by Dr. CHARLES MCNEIL and Dr. W. A. ALEXANDER. From statistics it was shown that, while lobar pneumonia occurred with fairly equal frequency throughout childhood, the cases of broncho-pneumonia were concentrated in the first three years and that this latter type of disease accounted for about 90 per cent. of the total deaths. Difficulties in the diagnosis of pneumonia and in the differential diagnosis of the two types were then discussed and illustrated. Examples of special types of lobar pneumonia—"cerebral," "abdominal," and chronic—were then given; and of certain sequelæ of broncho-pneumonia, such as bronchiectasis and fibroid lung.

Dr. ALEXANDER showed a series of lantern-slides illustrative of the pathology of pneumonia in childhood. These included photographs of paraffin sections of whole lungs prepared in the laboratory of the Royal College of Physicians of Edinburgh. The speaker believed that lobar pneumonia occurred throughout infancy, but that the prognosis was good, and few opportunities were afforded of studying the disease in the post-mortem room. Only one slide of typical lobar pneumonia was shown from a child of 3 years of age. Almost all the fatal cases were examples of broncho-pneumonia. There was a great tendency for confluence to occur in infancy. Broncho-pneumonia was characterised by an acute interstitial inflammation which overshadowed and often preceded the alveolar exudation. The extent and degree of this

involvement of the connective tissue framework of the lung determined very largely the seriousness of a case and also explained most of the complications and sequelæ—e.g., suppuration, bronchiectasis, and fibrosis. The problem of broncho-pneumonia in infants in Scotland was an urgent one, and in the opinion of the speaker much might be done in the matter of prevention by an attack on those factors which made for susceptibility to infection. There was much experimental and clinical support for the contention that dietetic considerations were all-important in relation to acute respiratory infections at that period, when the energies of the body were devoted almost entirely to active growth.

Reviews and Notices of Books.

AN INTRODUCTION TO MEDICAL PROTOZOOLOGY.

With Chapters on the Spirochætes and on Laboratory Methods. By ROBERT KNOWLES, B.A. Camb., M.R.C.S., L.R.C.P., Lieut.-Colonel, Indian Medical Service; Fellow of the Asiatic Society of Bengal; Professor of Protozoology, Calcutta School of Tropical Medicine. London: W. Thacker and Co., 2, Creed-lane, E.C. 4; Calcutta: Thacker, Spink and Co. 1928. Pp. xii. + 887. Rs.25.

DURING the past four years there have been published a series of text-books devoted to the medical aspects of protozoology. First, there appeared Hegner and Taliaferro's "Human Protozoology" in 1924, Craig's "Manual of the Parasitic Protozoa of Man" in 1926, and Wenyon's "Protozoology" in the same year. Now we have Knowles's "Introduction to Medical Protozoology." It is inevitable that each book should have taken advantage of the previous publications, and this is candidly admitted by the last author who says in his preface that he has looted or borrowed wholesale from Wenyon's work as also from Dobell's "The Amœbæ Living in Man," and Dobell and O'Connor's "The Intestinal Protozoa of Man." Nevertheless, the author has done his work well and has given to students of protozoology, especially the Indian students whom, above all, he has in mind, a clear, up-to-date, and easily readable account of the parasitic protozoa of man and animals and the coprozoic forms which occur in fæces.

The book is divided into three parts, followed by an index. Part I. (625 pp.) describes in a series of 19 lectures the main facts which are known regarding the parasitic protozoa of man, with sufficient reference to the allied forms in animals to enable the student to realise the extent and distribution of this group of organisms. Part II. (143 pp.) deals with laboratory methods and is divided into seven chapters in which are described methods of technique which are likely to be required for the study of protozoology in its relation to medicine. Part III. (92 pp.) is devoted to references to literature and includes all the important publications on the subjects dealt with in Part I. Finally, there is the index of 25 pages. The printed matter is sufficiently clear to be easily read, but the paper chosen does not do justice to the 174 figures, many of them "half-tones," which inevitably suffer unless good paper be used. An attractive feature of the book are the 16 coloured plates, although they are not of equal value. It has evidently been the aim of the publishers to keep the price down, so that for the modest sum of 25 rupees students can obtain a vast amount of trustworthy information regarding the present position of the subject.

The author's long experience of India naturally leads him to dwell on the Indian aspect of the questions dealt with and this in itself is one of the most valuable features of the book from the general reader's point of view. An interesting statement is made that the author has twice cured kittens experimentally infected with *Entamœba histolytica* by the administration of a single large dose (5 mg.) of emetine. A practical point for the teacher is that splendid specimens of the monkey entamœbæ, which a indistinguishable from *E. histolytica* and *E. coli* man, can be readily obtained by giving high sali enemata to these animals. It is noted that practical every sweeper at the Calcutta School of Tropic Medicine is a healthy carrier of *E. histolytica*. A appendix to Lecture V. describes the diagnosis dysenteric stools, a coloured plate illustrating the c exudates in bacillary as contrasted with amœb dysentery, and two figures the appearance of Charco Leyden crystals, so often associated with amœb infection of the intestine. The mastigophora, includi coprozoic flagellates, the intestinal forms, trypan somes, and leishmania, and the allied flagellates insects receive considerable attention. The nam *Leptomonas* is regarded as a synonym of *Herpet monas*, Wenyon's definition of the latter not bei accepted, for the author doubts if the trypanoson forms occurring in insects are actually of this natur The author's account of the leishmania is of speci interest because of his extensive experience of t diseases caused by them, especially of kala-azar, India. It may be news to some that even in the pr antimony days the mortality from kala-azar was n higher than 70 per cent. The description of t development of the sandfly theory of transmissi and the work done in India on the development of t parasites in these insects is most interesting a instructive reading. As regards the actual tran mission of kala-azar by the India sandfly *Phlebotom argentipes*, though the distribution of the fly and t behaviour of the parasite in it point to its being t actual vector, the author believes that the fin proof by experimental transmission will not possible till the factor of host resistance to infecti has been thoroughly investigated. The trypanosom are carefully discussed and readers will find in t section all the latest information.

A section on the Cnidospiridia is followed by consideration of the Sporozoa, amongst which t parasites of malaria are most important and a fully described as regards their structure and behavio in man and the mosquito. The factors which influen the development of the parasites and many oth features of infections are carefully discussed. It pleasing to note that the author adopts a conservati attitude regarding species of malarial parasites oth than the three well-known types. An observation interest is that on three occasions *Chilodon* has be found in fresh enemata from the monkey *Macac rhesus*, by which means *Balantidium* can also readily obtained. Though the spirochætes are n regarded as protozoa they are fully considered. a final lecture are considered Rickettsia, Chlamydozo and cell inclusions, while certain notes on rabies ha been included. The practical section, includi methods of technique, warnings (with a colour plate of blood fallacies and puzzles), insect dissectio (by Ronald Senior White), and methods of drawin micrometry and enumeration bring to a close t descriptive matter of the book. Some minor erro in description and nomenclature do not detra appreciably from the general excellence of the wo

The book will undoubtedly be read by very ma students and workers who will profit immeasurab by the clear, lucid, and in places racy presentation o science which has now grown to enormous dimensio

MATERIA MEDICA, PHARMACY, PHARMACOLOGY, A THERAPEUTICS.

By WILLIAM HALE-WHITE, K.B.E., M.D., LL. Consulting Physician to Guy's Hospital. Ni teenth edition. London: J. and A. Churchi 1927. Pp. 712. 10*s.* 6*d.*

THREE years have elapsed since the last edition this valuable little book appeared, and a number new therapeutic agents have established themselv in that period. Among those described for the fi time are mercurochrome, sanocrysin, methyl alcoh oil of chenopodium, and hydnocarpus oil. Old dru in new settings are lead for cancer, bismuth

syphilis, and carbon dioxide for anæsthesia. Parathyroid is added to the glandular group, and among the bacteriological substances now in recognised use are scarlet fever antitoxin, toxin-antitoxin mixture, and horse serum. Protein therapy receives a page to itself, but its uses are wisely confined to hay-fever and asthma, with a brief reference to the other anaphylactic conditions. The whole text has been thoroughly revised, and the book remains one which no medical student or practitioner can afford to be without.

PHARMACY.

Whys in Pharmacy: A Compilation of Reasons underlying the Principles of Pharmacy. Third edition. By EDSEL A. RUDDIMAN, Pharm.M., M.D. London: Chapman and Hall, Ltd.; New York: John Wiley and Sons, Inc. 1927. Pp. 203. 10*s*.

APART from a few pages of chemical equations and an index, this work consists entirely of short paragraphs each comprising a question and an answer, e.g., "Why should such substances as calomel and pecacuanha be very finely divided? The finer the powders the more active they seem to be." The subtle dubiety of the "seem" almost suggests that this compilation is a variant of a game of question-and-answer, popular in the columns of some of our daily papers. The fact, however, that the preface to the first edition, dating from 1905, disclaims any intention of "quizzing" leaves the purpose of the manual obscure. The paragraphs are grouped by an arbitrary division according to subject matter.

BLOOD TRANSFUSION AND GROUPING.

La Transfusion de la Sangre. By JULIO CÉSAR ESTOL. Montevideo: Palacio del Libro. 1927. Pp. 256.

Die Bluttransfusion. Von Dr. E. KUBÁNYI. Berlin and Vienna: Urban and Schwarzenberg. 1928. Pp. 127. M.6.

Rassenunterschiede des Blutes. Von Dr. WALTER SCHEIDT, Privatdozent für Anthropologie an der Universität Hamburg. Leipzig: Georg Thieme. 1927. Pp. 109. M.4.80.

MONOGRAPHS on blood transfusion are gradually being produced in every quarter of the globe. We have already had examples from England, the United States, France, and Germany. Two of the volumes now before us were written in South America and Hungary respectively. The purpose of such works is to provide a comprehensive account of the subject rather than to embody new material and observations. This object seems to have been attained in the works under review. The indications for transfusion are much the same all the world over, and the technique differs only in detail. Dr. Estol favours the use of a syringe, the interior of which is rinsed with citrate solution. This method is justified in his practice by the fact that the amount of blood given at one transfusion is very often less than 200 c.cm., a surprisingly small quantity judged by the standards recognised in this country. Even for severe hæmorrhage for a gastric ulcer or of traumatic origin an amount exceeding 300 c.cm. is the exception rather than the rule. A great part of Dr. Estol's book is taken up by tables recording the details of the 467 transfusions which he has himself performed.

Dr. Kubányi's book is of rather wider range and takes more account of the work done on the subject in other countries. It is the more surprising that, in view of the results obtained at St. Mary's Hospital, Dr. Kubányi should pronounce emphatically against the use of defibrinated blood. He himself favours the use of citrated blood which is injected into the patient's vein by means of a syringe. His monograph is well illustrated, and gives a very lengthy list of authorities.

The racial distribution of the blood groups has for some years been recognised as a possible source of light upon the problems of the origin of the different races of mankind. In the small volume before us Dr. Scheidt gives a comprehensive survey of the observations that have so far been made, with special reference to the incidence of the groups among European peoples. Much work remains to be done before definite conclusions can be made, although the present report embodies material from 203 different publications.

MEDICINE FOR LAYMEN.

The Human Body. By L. CLENDENING, M.D. London and New York: A. A. Knopf. 1927. With 103 figures. Pp. 399. 25*s*.

Medical Science for Everyday Use. By SHIELDS WARREN, A.B., M.D., Instructor in Pathology in the Harvard Medical School. Philadelphia: Lea and Febiger. 1927. Pp. 179. $2.00.

That Body of Yours. By JAMES W. BARTON, M.D., Medical Director, Canadian Health Service Institute. London: Hodder and Stoughton. 1927. Pp. 304. 2*s*. 6*d*.

Dr. Clendening has set out to write an account of the human body, its anatomy, physiology, and diseases, which shall be a suitable text-book for such grown-up men and women as want to know about such things. Proceeding with that entertaining air of cynical frivolity which has had a vogue in American wit in recent years, he has, we think, succeeded extraordinarily well in a very difficult task. The book is a sort of "family physician up to date," and the method of treatment reflects the changed outlook of modern medicine; instead of discreet references to the symptoms which may arise from the diseases to which females are peculiarly liable, and the drugs which may be taken to alleviate them, we have a clear well-illustrated account of pregnancy, parturition, fibroids, and carcinoma; a description of the anatomy and physiology of respiration leads on to pneumonia and phthisis, and so with the other systems of the body. The layman's idea of medicine is, in short, to have the same basis of fundamental knowledge as the doctor's; which is a very admirable plan. The good common sense and absence of faddism are particularly notable: "Your bowels, like the universe, will get on very well if you leave them alone" (p. 100), the treatment of phthisis (p. 120), the manufacture of invalids by periodic health examinations (p. 170), the necessity of every diabetic being under the care of a physician (p. 183), the advantages of picking up sex knowledge in the gutter (p. 277) are some examples; and there is hardly anything about vitamins. There is, of course, a good deal to which some people may take exception. It has been unusual in the past for a doctor to take laymen so frankly into his confidence, and the book is so intensely up to date that it necessarily contains a good many dogmatic statements on points about which there is no professional unanimity; indeed, it dwells so much on the growing edge that older medical men will probably find it as useful as their younger colleagues will find it provocative. Some people will think that such serious matters should be treated with more solemnity, and the contemptuous references to organised religion (e.g., p. 315) are, in this country at least, offensive. What proportion of the general public really wants to know what this book tells them so well is a speculative question; we suspect that a good many people are quite indifferent about the details of their own insides. But to the curious it may be recommended, with some interest in their reactions to it. What is known as "physiology and hygiene" is now widely taught in schools; no doubt it is time that adults should have corresponding opportunities of education.

Dr. Warren's book consists of articles which have appeared in the Boston *Sunday Herald*, selected, rewritten, and collected into a small volume which is excellent of its kind. The articles are clear, not too elementary, free from prejudice, and above all

interesting to read. There are 23 of them, and it is difficult to single out any for especial praise, but those which appear to be the most valuable are on tuberculosis, cancer, diphtheria, pneumonia, and heart disease, all maladies in which the death-rate offers ample scope for preventive measures. Dr. Warren quotes freely from recent work, interpreting scientific papers for his lay-readers in a sensible way, and steering a very good middle course in such troubled waters as "auto-intoxication."

Dr. Barton's book sets out with the same high ideals which have so successfully stimulated Dr. Warren, but he has attempted too much, and the result lacks continuity, while it is not altogether free from errors. For example, in a section on "fits," the author ignores the necessity for the proper treatment of epilepsy by sedative drugs, and instead gives the impression that diet and exercise are of greatest importance in lessening the number and severity of fits. Certain sections of the book are very good, particularly those on the feet and those in which the body is likened to a motor-car. As from the preceding books, the public will derive sound counsel here upon much that matters.

PERSONAL HEALTH.

By Prof. EMERY R. HAYHURST. London: McGraw-Hill Publishing Co., Ltd. 1927. Pp. 279. 15*s*.

On Middle Age and Keeping Young. By Dr. E. L. HOPEWELL-ASH. London: Mills and Boon. 1927. Pp. 121. 3*s*. 6*d*.

IT has been estimated that 75 per cent. of illness could be warded off or controlled if everyone applied the hygienic and medical knowledge now available. This may seem too optimistic an estimate, but there is little doubt that the great increase in good books on personal health and hygiene should eventually show a harvest of better physique among people who take the trouble to read them. Prof. Hayhurst, of Ohio, has written an excellent manual for "the busy person in shop or office." He discusses in some detail the purposes of the principal organs and parts of the body which should be the common knowledge of all intelligent persons, and he deals with the principal diseases, their causes, symptoms, prevention, and early treatment. The book is attractively written and well produced, and although its price is high for the type of individual to whom it should appeal it is well worth the money.

Dr. E. L. Hopewell-Ash's little book deals with the personal health and hygiene of the middle-aged, but we do not find the subject matter sufficiently well presented to appeal to the more intelligent class of reader. It does not help the woman at the time of the menopause to be told to "hold on whilst this natural crisis of life affects you," and the student of dietetics will wonder what the author means when he writes, "Nothing is digestible if it is mixed with too much of other things at the same time." Moreover, although the author doubts it, Sir Archibald Garrod is (happily) still alive. Of course, most of the advice given will be found serviceable.

JOURNALS.

A GERMAN JOURNAL OF ANÆSTHESIA.—A new journal, *Narkose und Anaesthesie*, has appeared in Germany, the first number being published in Berlin on Jan. 15th. This is a novel production, for it is the first time that a periodical has been issued in Germany, or, indeed, on the continent at all, which is devoted solely to the study of anæsthetics. In fact, the publisher, in his foreword, comments on the comparative backwardness of German medicine, contrasted with that of England and America, where the study and practice of anæsthetics are concerned, and he alludes to the *British Journal of Anæsthesia* and the "Current Researches in Anæsthesia and Analgesia" as worthy of imitation. This number of *Narkose und Anaesthesie* comprises a long article on new routes for the anæsthesia of the jaw and face which is entirely occupied with local measures. The other important original article deals wit avertin. The nature of these two contributions significant of the relative importance of inhalatio anæsthetics and other methods in Germany. The is no mention of the former in either of the tw original articles in a new journal devoted solely t anæsthetics. We welcome *Narkose und Anaesthes* as a valuable addition to current literature and on which will enable our readers to be kept in touc with the latest developments of anæsthetic study i Germany.

THE GLASGOW MEDICAL JOURNAL: CENTENAR NUMBER.—The February issue of the *Journal* appea on the hundredth birthday of this valuable periodica and its history and progress are well set out in a article, charmingly illustrated, which deals with th personalities of a long line of interesting editor commencing with William Mackenzie, at that tim Andersonian professor of anatomy and surgery in th University. The opposition to the journal in its earl days was conducted on very similar lines to thos which were adopted by some of the early rivals t THE LANCET, and the use of nicknames was similarl employed. The short-lived *Glasgow Medical Examine* which had a yellow cover, was particularly seve upon the *G.M.J.*, but the "Mustard Plaster," as was dubbed, proved unlucky in its criticisms, f one of the principal sources of grievance against th *G.M.J.* was its support of Lister and Lister's do trines. We note here, with complacency, that TH LANCET is adduced, under a very dignified sobrique as being on the side of the angels, its pages havin been "open to the insertion of every communicatio of the Professor on the extraordinary facts of th antiseptic and atmospheric germ killer." We do no attempt here to do more than note the appearanc of this extraordinarily interesting centenary issue the articles form not only a domestic history of rea importance, but in many respects a valuable revie of our science throughout the period. The editor an his collaborators deserve hearty thanks and no les hearty congratulations.

JOURNAL OF INDUSTRIAL HYGIENE.—January, 1928 Attention is directed by C. K. Drinker to the baro spirator of Prof. T. Thunberg, a new apparatu for artificial respiration, planned on entirely origina lines. The air is introduced into the chest, an removed, by altering the pressure of the atmosphere o the chamber in which the body is placed. When a ordinary person is placed in the chamber and th apparatus for rhythmically increasing and decreasin the pressure of the air is set working, he soon lose any need for using his own respiratory muscles an continues carrying on quite happily without an visible signs of breathing; nor, indeed, are th ordinary movements of inspiration and expiratio taking place. Barospirators must always be rathe cumbersome affairs, but they offer a possibility o treating cases of respiratory failure hitherto unap proachable. One such an appliance centrally situate could serve a large area for cases where a long struggl is evidently at hand, in cases of electric shock, ga poisoning, or drowning. The author considers tha the undoubted efficiency of the barospirator makes i certain to come into use.—The last article, which i contributed by P. Drinker, R. M. Thomson, and J. I Finn, describes experiments carried out for ascertainin the amount of inhaled dust which is retained. Th particles used varied in size from about 0·4 micron i one series of experiments to 0·15 micron in anothe and up to 6 microns in a third. Details are given o 41 experiments in tables and graphs, showing th amounts inhaled, exhaled, and retained. Th percentage retentions in all three suspensions average 55. The importance of this piece of research work i considerable as standards of dust contamination o atmospheres cannot be fixed for administrativ purposes unless it is known how much of the dus inhaled is retained. Curiously the amount retaine does not seem to depend on the size of the particle since the same proportion was retained in each of th series of experiments reported.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 25, 1928.

EUGENICS AND A NATIONAL STOCK-TAKING.

FOLLOWING the annual dinner of the Eugenics Society, which was held in London last week, the Galton Lecture was delivered by Mr. C. J. BOND who asked his hearers to consider the present distribution of natural capacity in our population, implying by natural capacity the inborn physical and mental qualifications for good citizenship. Having adduced all the arguments, that can as yet be supported by facts, to show that our fluctuations as a race are unpromising in both respects, he pleaded for a national stock-taking in respect of mental and physical conditions and for the close coöperation of the medical profession in the collection and collation of data. Mr. BOND began his address by outlining the factors which had led to the decline of earlier civilisations, and followed well-known lines in showing that a cyclical process of periodicity is a marked feature in the life-history of civilisations and of races, as it is in that of the individual organism. This may be regarded as an essential message of history, but it is not easy to keep in mind the analogy between the growth, the perfected maturity, and the decline of the individual and the similar rising and falling of a dynasty or even a nation. Daily and personal experience makes the sequence easy to appreciate in contemporary individuals, but a historical sense, and no less a historical prescience, are demanded in order to gauge the measure with which the race conforms to the individual pattern. The progression and retrogression of the mass are more complicated than anything that occurs in the individual, because society goes neither forwards nor backwards as a symmetrical whole; its physical development usually precedes its mental development with the result that the finest artistic manifestations of the race may occur at an epoch when the accumulation of wealth is marked, but when its sources may already have begun to fail, so that the greatest average level of well-being may no longer exist. Further, as the Galton Lecturer showed, an inverse relationship between a high degree of specialisation such as is implied by great material prosperity and the reproductive capacity seems to be the fundamental characteristic running throughout life; in other words, those who best exemplify the culture of the race are those who present the least chance of increasing the value of the stock. Just as the more highly specialised brain cells in the individual lose the power to reproduce themselves, so the fecundity of more highly specialised groups in any community fails, and this fact, apart from its general genetic interest, has an intimate bearing on racial decline. This conclusion is of course debatable for one reason; we have not yet full knowledge of the part that is played in family statistics by voluntary control.

The general message which the Galton Lecturer delivered, and supported by evidence in many directions, is that the life of a nation is the expression of hereditarily transmitted racial groups of mind and body, and the subservient position which all that is usually called environment appears to play in that message is explicable by including under the head of environment many and various circumstances which may trace an origin to social heritage. Even a casual consideration of these circumstances proves that national life, as influenced alike by nature and nurture, must be renewed from below upwards, if only because the issue of the higher strata of society is too small in bulk and that of the lower strata is too large; the intermingling process takes place chiefly in the middle strata which represent the average citizen and thus form the bulk of the population. In respect of this position Mr. BOND compared the fecundity of the lowest social groups—those including mental defectives, habitual paupers, and innately criminal—to the phenomena of the parasitic cancer cell in the individual organism, where the cells multiply, but multiply in fulfilment of no special or useful purpose, until by their very multiplication the death of the whole organism is brought about. Regarded in this way racial decline may be called the direct biological effect of breeding from degenerate and inferior stocks, the decline in highly organised communities being aggravated by the fact that the worthier citizens, by as much as they have to bear the burdens laid upon them by the unworthy, are by so much the less fitted to meet their own responsibilities. This is the position in which the Galton Lecturer conceived that the British race stands to-day, and he summarised the evidence, both weighty and many-sided, which he thought pointed to the occurrence of deterioration in the mental and bodily qualities of our people. His words will appear in full in the April issue of the *Eugenics Review*. Medical men do not need to be reminded how far Mr. BOND'S thesis is supported by the Army recruiting statistics, in particular those of 1903, by the report of the Inter-Departmental Committee on Physical Deterioration which appeared in 1904, by reports from the Board of Control on the numbers of insane and mentally defective persons, and by the Galloway Report to the Ministry of National Service on 2½ millions of men of military age in Great Britain in 1917 and 1918. The lesson of all these reports is the same in essence—we are far from eugenically perfect.

Any conclusion that a real deterioration in physical and mental qualities is going on in certain sections of the population, and by a process of infiltration is producing results which will multiply in geometrical progression, makes the proposition for a national stock-taking into an urgent demand. And the outcome of an organised numbering of the people, if the investigation was full and thorough, might put a more cheerful complexion upon the future. It is reasonable to believe that many of the ills whose existence cannot be contradicted are more sporadic than general, and further, that vicious processes may often be found in a condition where well-directed methods can lead to their arrest. It is an inspiration of hope rather than one of fear that will lead the medical profession to support the desire of the Eugenics Society for a national stock-taking, while in securing the right evidence the coöperation of doctors must be of paramount importance. In describing the kind of census needed Mr. BOND suggested that inquiry into the distribution of natural capacity would be assisted by the inclusion in the census schedule for 1931 of the various questions of genetic or racial importance which had a place in the schedule for 1911, while more facts bearing on racial make-up should be brought to light by birth registration. Intensive inquiry, he thought, could be carried out in certain representative samples from children of school age, and Sir GEORGE NEWMAN'S reports to the Board

of Education have shown for many consecutive years how valuable the information obtained in this way must be. But we have to recollect that the school-children of the nation are themselves divided into two classes which are not comparable—those who are educated by the State and those who are not—that is to say, the children of the fruitful classes and the children of the more or less sterile classes, and again the difficulty appears, which follows on our ignorance as to how far the sterility is a matter of germ plasm, and how far of some deliberate interference. The factors already outlined as leading to this main difference as far as numbers are concerned will have to be taken into consideration when age-groups of the whole young population are being compared, and there will be ample room for unsound deductions if too much stress is laid upon the concinnity of the records. Here medical guidance will be particularly useful, because alike of the levelling character of disease and of the necessary acquaintance of the medical profession with the family history and domestic environment of all strata of society. We hope, therefore, that the Eugenics Society may receive active recruits from the medical profession, for the objects of the Society, while of supreme national concern, can be particularly advanced by medical effort. It may well happen that the progress which is taking place along so many lines of therapeutic research, when reflected in a national stock-taking, would lead to less gloomy views than those of common prophecy.

DOES INSULIN SAVE LIVES?

IN this country the experience of the last three years points strongly to the value of insulin as a means of reducing the death-rate from diabetes. This was made clear in a series of instructive graphs, which appeared in our own columns a few months ago,[1] based upon the Registrar-General's statistical review of England and Wales for the year 1925. But there was in these graphs one rather striking exception to the fall of the death-rate from diabetes—namely, the part of the curve dealing with women aged 55 and over. Why, it may be asked, should this curve not have followed the general course? Has there been in recent years such a reaction against the food restriction imposed during war-time as to account for the failure at higher ages to secure the reduced mortality shown in the young? The optimal diet in diabetes, as was pointed out in an annotation last week, is a matter on which opinions differ; and though the use of insulin has led to a relaxation in the diets recommended for cases of severe diabetes, there are facts, such as those set out by Prof. I. M. RABINOWITCH, which forcibly suggest the importance of encouraging abstemiousness amongst diabetics. Overfeeding in elderly people, and especially in elderly women, however, may not be entirely responsible for the relatively unfavourable course of the diabetic death curve at ages over 55, for it would be incorrect to certify all deaths in elderly people with glycosuria as due to diabetes; at long last even the diabetic must die. Considerations such as these lend interest to a further paper[2] by Prof. RABINOWITCH, giving the results of the experience of the use of insulin in the Montreal General Hospital for the years 1921–27 inclusive.

In this Montreal investigation all cases not under constant observation were excluded from consideration because it could not be assumed that these patients had followed treatment. The remainin 1316 admissions, on which the study is based, for a fairly representative sample of the general popul tion of diabetics, in regard both to age and sex. number of patients were neither seen nor heard after leaving the clinic. It can neither be assume correctly that these are all alive or all dead. Th author overcomes this difficulty by calculating bot a "known" and an "assumed" case-mortality rate in the first instance those missing are assumed to b all alive and in the latter all dead. The large majorit of the cases, however, were under constant super vision. In 1921, before the introduction of insulin the "known" mortality was 11·5 per cent., and fe to 1·1 per cent. in 1927. A similar result is foun with the "assumed" rate. In 1921 this amounte to 15·4 per cent. and in 1927 to only 2 per cen Insulin, therefore, appears to have greatly decrease the mortality-rate from diabetes. To overcome th statistical difficulty of comparison of the results different years, in which the age-distribution of th cases admitted to hospital may be different, and a the same time to furnish a fair index of the mortalit among diabetics in comparison with that of th population generally, the author has calculated fo each of the years 1921–27 the number of deat which wonld have occurred in his population diabetic patients had they been subject to the gener rates of mortality pertaining to different ages, an has compared these with the actual deaths. Th ratio of actual to expected deaths gives a clear insigh into the effects of any particular disease on mortalit In 1921 the death-rate among diabetics was foun to be 535 per cent. of the normal, in 1922 it actuall increased to 660 per cent.; but with the more gener application of insulin treatment in 1923, the ra fell to 280 per cent. of normal, and in 1927 to 10 In other words, insulin, effectively used, seems to h able to effect a "cure" in the sense of placing th patient, as regards mortality, in a position equal t that of the general population. Examination separate age-groups reveals the fact that, althoug the disease was and still is much more fatal in ear life, the decline in the case-mortality with the applic tion of insulin is greatest at these ages. Whereas in pre-insulin days, the ratio of actual to expecte deaths at ages under 20 was more than seven tim as great as the ratio at ages 40–60 years, since insul treatment was introduced the ratio at ages und 20 is barely three times as great as at 40–60 year The risk of performing surgical operations for co ditions arising during the disease can, moreover, effectively minimised by the exhibition of insuli Prior to its general use, in 1921 and 1922, 21 operatio were performed with 8 deaths, a case-fatality 38 per cent. In 1925 and 1926 there were 76 operatio with only 4 deaths, a case-fatality of only 5·2 per cen Diabetic coma was responsible for 50 per cent. deaths in 1921–22, whereas in the insulin perio 14 per cent. only were due to this cause.

Results such as these provide a striking contra with the gross recorded mortality from the disea among large populations in England and Wales, well as in Canada and the United States, where t recorded death-rate has in many instances shown actual increase. Classification by age-groups mig give the figures a different complexion, whilst t greater attention paid to the disease, improv methods of diagnosis, or an actual increase in t incidence of diabetes may all be playing their pa Nevertheless a discrepancy seems to remain betwe what insulin can do and what it actually does. Pr RABINOWITCH concludes that either the drug is n

[1] THE LANCET, 1927, i., 1365.
[2] Canadian Med. Assoc. Jour., 1927, xvii., 1415.

being used when it should be, or, if it is used, it is not used properly. Of these, he believes the latter to be the more important factor.

CARE OF THE MENTALLY DEFECTIVE.

THE Mental Deficiency Act, which was passed without opposition at the end of the last Parliamentary session, is a small one of only 11 sections; it is nevertheless of considerable importance to local authorities as well as to all medical practitioners who may be called upon to deal with mental defectives. We therefore welcome the explanatory circular No. 702 which has just been issued by the Board of Control. The Act is an amending one, its main purpose being to remove certain difficulties which have been experienced in the practical working of the principal Act since this was passed in 1913. Many of these difficulties centred round the definition of mental defect, and undoubtedly the alterations of chief importance to the medical profession are those which relate to such definition. It will be recalled that in the original Act it was required that, before a person could be dealt with as a mental defective, the defect must have been present "from birth or from an early age." We believe the intention of these words was to ensure that other forms of abnormality, such as those arising from disorder or deterioration, should not be dealt with as mental defect. In many quarters, however, this purpose has not been appreciated, and the words have been interpreted literally and as meaning the first few years of life. This restricted interpretation has been found to result in the exclusion from the Act of many persons who are unquestionably mental defectives, and for whom its provisions were intended. For instance, all with practical experience of defectives are aware that while the lower grades of idiocy and imbecility are usually recognised without difficulty in the early years of life, it is far otherwise with those suffering from the milder grades of feeble-mindedness. In many of these the deficiency may not reveal itself until towards the end of the first decade, or even not until adolescence. Again, it is by no means uncommon for mental defect to be brought about at these later ages by injury or disease of the brain. Common examples of this occur in the various forms of meningitis and encephalitis, as well as the arrest of mental development induced by epilepsy. During the past few years some hundreds of children have been rendered mentally defective by encephalitis lethargica; but, as the original definition stood, it was found impossible in many cases to deal with these as defectives and to secure their admission to institutions under the Act, although such institutions might afford the most suitable form of treatment. In the Act of 1927 the words "from birth or from an early age" are deleted, and there is given for the first time a definition of mental defectiveness—viz., "a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by disease or injury." This definition must, of course, be read in conjunction with those of the four classes of defectives which precede it; but there is no doubt that the changes will go a long way towards remedying the difficulties we have alluded to, as well as towards making clear who are, and who are not, defectives.

As the circular points out, the essential criterion of mental defect is not a defect of intellectual capacity, as this term is usually understood; for mental defect may exist in persons of considerable intellectual capacity. It is an incapacity for efficient social adaptation of such kind and degree as to render the person in need of care, supervision, and control. A person who suffers from any defect of mind, arising before the age of 18 years, which is sufficient to necessitate external care is a mental defective within the meaning of the Act. It may be pointed out that the designation of the fourth class has been changed from moral imbeciles to moral *defectives*, and that the words "on which punishment has had little or no deterrent effect" have been deleted from the definition of this class. No doubt this change will be an advantage; indeed, we are inclined to regard it as somewhat unfortunate that the opportunity was not also taken to redraft the definition of ordinary imbeciles. They are still defined as "incapable of managing themselves or their affairs"—a perfectly true definition, but one which conveys a somewhat misleading view of the marked incapacity of this class. The remaining sections of the Act to which the circular draws attention are either drafting amendments or administrative changes. The most important of these may be briefly referred to. Although the principal Act permitted parents in a position to pay fees to place their defective children in suitable institutions, it made no provision for such as were unable to pay fees to do this, unless it could be showed that these children were "neglected, abandoned, or without visible means of support, or cruelly treated." This was found to be a hardship, and it is now remedied by allowing such children to be dealt with on the representation of their parents or guardians to the local authority that they are in need of care or training which cannot be provided in their homes. Another disadvantage existed in the case of children about to be discharged from special schools. These pass out of the jurisdiction of the local education authority at the age of 16 years, and, if their supervision is to be continued, they must be notified to the local (control) authority. But the education authority has hitherto only been empowered to do this in the case of children needing to be sent to institutions or placed under guardianship. In many cases neither of these courses is necessary; all that is needed is supervision, and Section 2 of the Act now enables the child to be notified for this purpose. The circular draws attention to the difficulty which has sometimes been experienced in the case of mental defectives coming before the courts. The court is empowered to direct that a petition be presented to have the defective sent to an institution; but where it has been impracticable to do this, or where the petition has been dismissed, there has hitherto been no provision for the detention of the person until the case could be suitably disposed of by the court. Section 5 provides the machinery necessary for this purpose. Section 7 of the Act imposes a new obligation upon local authorities. Hitherto they have only been required to provide suitable training for defectives in institutions; they now have the duty of providing this for defectives who are under guardianship or supervision. They may, however, be relieved of this obligation if they satisfy the Board of Control that there are adequate reasons for exemption. Hitherto local authorities have only been able to receive into their own certified institution patients from their own area; the Act now enables them to receive those from any other local authority, and this is a provision which may be of decided advantage to small authorities, who will thereby be enabled to board out their cases until such time as they can provide their own accommodation.

While the amendments and additions to the Act, to which this circular directs attention, will be of especial concern to local authorities and to medical men holding

official posts, some of the changes, particularly those of definition, are of importance to the medical profession as a whole. The time has arrived when few general practitioners can afford to be without an adequate working knowledge of mental defect in its relation to education, conduct, and citizenship. It is quite certain that more general use might be made of the course of instruction arranged by the London University Extension Board in coöperation with the Central Association for Mental Welfare, and intended primarily for medical men holding official positions. The course is based on the requirements of the syllabus for the University diploma in psychological medicine. Series of lectures will be given by Dr. A. F. TREDGOLD, Dr. F. C SHRUBSALL, Prof. CYRIL BURT, and Dr. NORWOOD EAST, and the clinical work will include visits to special schools and residential institutions. A certificate of attendance is granted. The next course will be held from May 14th–19th at the University, Imperial Institute-road, South Kensington, and communications in regard to it should be addressed to Miss EVELYN FOX, University Extension Department, at that address.

Annotations.

"Ne quid nimis."

TESTIMONIAL TO SIR DAWSON WILLIAMS.

ALLUSION was made recently in these columns to an admirable intention to present a testimonial to Sir Dawson Williams, who lately retired from the Editorship of the *British Medical Journal*, after 30 years in that position and nearly 50 years close connexion with the editorial work of the paper. There is a widespread feeling that the occasion should not pass without some recognition, from the profession as a whole, of his long and distinguished services to the science and practice of medicine. We understand that it is accordingly proposed to issue a general appeal and to send to the medical press a first list of supporters for publication on March 10th. Those wishing to be included in this list are invited to send their contributions, not later than March 3rd, to Sir StClair Thomson, who has been asked by the provisional Executive Committee to act as honorary treasurer. Though the Committee does not wish to limit the amount of individual donations, it hopes that the sum eventually received will include a large number of contributions of two guineas or less and so represent the profession generally. Cheques should be made payable to Sir StClair Thomson and sent to 64, Wimpole-street, London, W. 1, and the envelopes marked "Dawson Williams Testimonial."

CHOLERA IN IRAQ.

THE epidemic of cholera which broke out in Iraq in the summer of 1927 gave an opportunity to test the efficiency of prophylactic inoculation, of measures for the purification of the drinking-water, and of the working of quarantine restrictions. Happily full use was made of this opportunity, as may be seen from the report [1] of Dr. C. P. Thomson, president of the Egyptian Conseil Sanitaire. On July 20th the medical officer of health of Basra observed two suspicious cases, and several were found at the same time at Abbadan, but it was not till July 23rd that a bacteriological diagnosis was made. It says much for the promptness of the medical officers concerned that travellers who had left the infected area on the morning of the 23rd were received on the morning of the following day at the aerodrome in Cairo with unusual attention by its quarantine medical officers. The epidemic in Abbadan served to demonstrate once again the importance of a contaminated water-supp in the spread of this disease. Among the 80 inhabitants supplied with filtered water there we only eight cases of cholera, whereas among t remainder, numbering 22,000, whose water-supp was not filtered, there were 273 cases. Accordi to a short note addressed to the Office Internation by Dr. Djavad Asthiany, the epidemic was suppress by Oct. 25th, thanks to the provision of sanita cordons and vaccination. More than 40 per cen of the inhabitants in the infected towns and t adjoining areas were vaccinated, a supply of vacci sufficient for 700,000 doses having been provide Dr. Thomson notes that, although much importan was attached to vaccination, sanitary cordons we found to be necessary, and the movements of no vaccinated persons on the principal lines of communic tion were strictly regulated. The total number cases notified up to Nov. 5th in Iraq was 103 among which there were 756 deaths. Two new lines communication have now to be considered in connexi with any outbreak of cholera in Iraq. The fir is the air route from Cairo to Basra by Palesti and Baghdad. The weekly aeroplane takes 12 hou from Cairo to Baghdad and 27 hours from Cai to Basra, for it does not fly by night. When t route has been extended to Karachi, a traveller fro an infected centre in India may, in three and a h days, find himself on board ship at Port Said. T other new line of communication is the motor-c route between Baghdad and Beirut, via Damascu The journey takes only 29 hours, and the traffic this route is increasing continuously. About 2 travellers pass this way every week, and in 1926 abo 2000 pilgrims made use of it to reach Jedda These two new routes and the discovery of oil Iraq give point to the remark recently made th Iraq has ceased to be oriental and has come to part of Europe. It is fortunate that with the extended facilities for the transmission of disea there should be an effective quarantine netwo at points of landing. The medical authorities Syria control the motor traffic, of which Damasc is a centre, and the aerial traffic is under strict medic supervision in Palestine and Egypt. In order n to hamper the development of these new lines communications, the medical authorities in Egy intend to make sanitary restriction as light as possib compatible with safety. Travellers coming fro infected regions, reaching Egypt by aeroplane, a wishing to catch boats bound for European port may continue their journey without observation quarantine at the aerodrome, provided they can sho that they have received two injections of a chole vaccine, the second of which was given at lea six days earlier, and provided also that they loo quite well. The medical officer of the ship by whi they travel from Egypt must be told where th came from.

GAIT, NORMAL AND ABNORMAL.

EVER since the days of the brothers Weber, who book on the human mechanism was published mo than 90 years ago, physiologists and surgeons ha from time to time made attempts to analyse a record the movements of the body and limbs locomotion. Some of these attempts have been fair successful, especially since instantaneous photograph has come to the observer's aid, but the practical valu of the records has been small. During the war very elaborate and efficient cinematographic apparat was constructed in the experimental workshop of t Ministry of Pensions and excellent photographic char were obtained of normal gait and also of the gait of man wearing an artificial limb. These records we described and commented on by Mr. R. C. Elmslie a paper published in the *St. Bartholomew's Hospit Journal*,[1] and the charts and photographs were repr duced by Mr. Muirhead Little in his book on Artifici Limbs.[2] Excellent as these photographs and tracin

[1] Office International d'Hygiène Publique, Bulletin, vol. xix., No. 11.

[1] September, 1920. [2] 1922 (H. K. Lewis).

were technically, they were not of much value to surgeons and limb-makers in the re-education of the amputee, or for perfecting the mechanism of artificial limbs. The subject has been re-examined lately in the United States by Dr. R. Plato Schwartz, of New York, and Mr. William Vaeth, who brought an instrument devised by them and called a basograph before the Section on Orthopædic Surgery of the Seventy-eighth Annual Session of the American Medical Association, last year.[3] Dr. Schwartz does not seem to be aware of the cinematographic work that was done in this country during the war, a knowledge of which might possibly have affected his conclusions. His apparatus consists essentially of a pendulum and a recording tambour, which are enclosed in a case and carried on the subject's pelvis. The tambour is driven by a modified Cine-Kodak motor but the details of the whole are too elaborate to be described in a short note. The resulting graphic records resemble in appearance those of a sphygmograph or a barograph. The orthopædic surgeons who took part in the discussion of this paper, while all appreciating highly the industry and ingenuity displayed by the inventors, seem to have been doubtful of its practical value in guiding treatment. Tracings of limping gaits, although they may show definite aberrations from the tracings of normal gait, yet will no more tell us in what part of the complicated neuro-muscular-articular mechanism the fault lies than will the eye of the surgeon. Nevertheless all knowledge is to be welcomed for its own sake, and no man can tell at first in what way it may be ultimately useful. Dr. Schwartz has been working on the right lines, more on the traditions of Aristotle than of his philosopher namesake. We regret that death has deprived us of the former doyen of New York's orthopædic surgeons, Dr. Virgil P. Gibney, who would no doubt have supported Dr. Brackett, of Boston, in encouraging Dr. Schwartz.

PEPYS AS A MEDICAL COMMENTATOR.

Pepys's versatility, along with his frankness, humour, and zest in life, have made him immortal. There are few phases of life in the seventeenth century upon which he does not touch in his diary, and of those outside his own occupation in the Navy Office medicine is one of the most prominent. It is true that, as Lieut.-Colonel W. P. Macarthur remarked in a most able address at the social evening of the Royal Society of Medicine last week, he was considerably more interested in fair ladies than in any number of grave doctors of physic, but his journal abounds in medical references, and contains, together with that of John Evelyn, a considerable body of information on the medical knowledge and practice of the time. The high regard in which he held the science is in surprising contrast to the contempt and distrust freely expressed by many other writers. It may be that Pepys owed the preservation of his sight, after he had resigned himself to its loss, to the counsels of his medical friends. First-hand experience, even of the terrible surgery of those days, did not destroy his goodwill to the profession, for he used to carry about with him and exhibit a calculus "the size of a tennis-ball" which he had had removed from his bladder. Had he lived in these days, suggested Colonel Macarthur, he might have found this hobby somewhat exacting; he would probably have carried on him, besides his stone, a pair of tonsils and an appendix in another pocket, a handful of teeth among his loose money, and a section of large intestine knotted round his waist.

Pepys's observation of contemporary epidemics was very keen. The earliest one he mentions was in the summer of 1661, "a sort of fever" which spread over London and its surroundings. He connects it with an unusually warm autumn and winter, which in fact caused Parliament to appoint a day of fasting and prayer for more seasonable weather. From accurate records made by Sydenham at the time, it seems probable that the disease was malaria, and, as Colonel Macarthur reminded his audience, it is only in the light of recent observations that we can appreciate his accuracy. The artificially induced malaria used to treat general paralysis of the insane begins as a continuous fever and only later does it become intermittent. Sydenham says that intermittent fevers do not at once put on their full shape and are at first hard to distinguish from continued fevers; only when their violence is a little quelled is their intermittent nature apparent. Pepys could, of course, hardly help noticing small-pox, and Colonel Macarthur quoted at length his account of the tragic disfigurement of the lovely Frances Stewart, Duchess of Richmond, who found favour, like practically every woman of those days with a claim to good looks, in the sight of the King, but whose character the speaker tellingly defended from the calumny with which it has been ignorantly defiled. Small-pox in the days of the Stewarts was a very serious pest indeed. Among its victims it numbered many of the royal family, and it ultimately cleared the path of the Elector of Hanover to the English throne. In Tudor times it was a comparatively trivial disease, often confused with measles, and Colonel Macarthur quoted the pathetic, bewildered protest of one Master Robert Langton, who found himself about to die of this childish complaint "which he never thought should have come to pass, seeing that it is but the small-pox." The mild variety of to-day strongly suggests that of the Tudor period, and it is interesting to speculate whether this form, like that of Pepys and Evelyn, will revert to its one-time malignancy.

Pepys's account of the plague is perhaps the most read part of his diary, and is certainly one of the most valuable contemporary accounts extant. Colonel Macarthur enriched his extracts from Pepys with prints of dead-carts and "searchers," and facsimiles of burial records of the period, showing columns of names monotonously franked with the ominous initial "P." As everyone knows, Pepys's outbreak was the last of the historic epidemics, for a revival of interest in sanitation condemned for ever the filthy streets and the "over-building" which gave the plague-rats a favourable soil in which to multiply. Pepys, who was no coward, stuck at his post until the deaths were numbering 6000 a week, and only quitted when his brewer, butcher, and baker had succumbed and he could no longer obtain supplies. In fact, Colonel Macarthur made it quite clear that Pepys was a much finer man than modern critics and dramatic representations make him out. He was an indefatigable, conscientious worker, a most efficient public servant, and an honest one by the standards of his time. Against any word condemning him on this score must be set the fact that the Crown owed him £28,000, not a penny of which was ever paid. If he had not possessed exceptional qualities of head and heart he would not have been President of the Royal Society, a Master of Trinity House, a Baron of the Cinque Ports, a Member of Parliament, and the esteemed friend and correspondent of men like Sir Isaac Newton, John Evelyn, and Hans Sloane. Medical men to-day, as in his own times, have good reason to hail him as a friend and sympathiser.

THE ASSESSMENT OF PUNISHMENT.

Dr. Norwood East's conspicuously reasonable lecture on Problems of Forensic Psychiatry, of which a full report is given in another column, may be regarded as a fair statement of the greatest common measure of agreement between the medical and the legal view. Sir Ernest Wild's observations at the conclusion of the lecture will also be read with the attention which any remarks of the Recorder of London deserve. When Sir Ernest Wild declares that to admit the defence of uncontrollable impulse would make justice impossible, he must be left to argue the point with the other learned lawyers who were members of the Atkin Committee. Another of his observations is worth emphasising. It was essential, he said, that the medical witness should speak from personal knowledge and

[3] Jour. Amer. Med. Assoc., 1928, i., 6.

experience ; in so many cases the wealthy person went to a doctor for the first time in order to get him as a witness. Sir Ernest Wild had in mind perhaps the class of case where a rich woman is prosecuted for shop-lifting and all the resources of all the professions are mobilised on her behalf. But it is hard to suppose that in such a case the court is unable to disentangle the relevant and first-hand evidence from mere irrelevance and hearsay. If the rich person's riches produce such an overwhelming weight of expert testimony that the scales of justice cannot be held even, the occasion would seem to be proper for the court to avail itself of existing facilities—or, if no facilities exist, to ask Parliament to furnish facilities —for summoning to its aid an expert assessor. The Recorder of Chichester lately expressed the opinion that there was no need for medical assessors in courts of law ; he preferred to obtain medical evidence from a medical expert in the witness-box. If, for want of special knowledge, the Court finds itself unable to cope with an overbearing or partial expert witness, the use of an assessor seems a simple remedy. Judges in Admiralty are not above consulting assessors who are experts in seamanship ; in ecclesiastical appeals to the Privy Council bishops may come and assist ; in patent and other cases assessors are found useful. Why is it only the medical assessor who is not worth summoning ? Has the limited use of assessors and referees in workmen's compensation proceedings proved so disastrous an experiment ?

INFLUENZA AND GENIUS.

Daniel Webster years ago said that influenza was the " crux of epidemiology," and it is well known to-day that the syndrome is no new disease, but an ever-present endemic, smouldering in the intervals of its periodic outbursts. Its great prevalences are favoured by war, famine, overcrowding, and free communication with patients in the early stages. While crowding and communication have hugely increased of recent years, we are able to put up against them the improved feeding, housing, cleanliness, and medical and nursing care that have succeeded in reducing the mortality during the last century and a half. This year there has been no serious epidemic, and it seems likely that the danger period will pass without more than sporadic outbreaks. This fact, however, must never induce forgetfulness or relaxation of vigilance, and the two Chadwick lectures delivered on Feb. 16th and 23rd by Sir William Hamer come as timely reminders that the enemy never sleepeth. The name " influenza" was first used in 1743, but Sir William, in common with other epidemiologists who have recently studied the question, followed its course from the " English Sweats " of 1485 and onwards, which were accompanied or followed by convulsive ergotism, epidemic agues, volatile typhus, and encephalitis or brain fevers. He traced the cycles of influenza from Willis's epidemic of 1658 through the intermittents of 1661–64 and of 1673–4 with an interval of depuratory fevers, to Sydenham's great outbreak in 1675, followed, like its predecessor, by intermittents between 1675 and 1679, a phase of depuratory fevers and more intermittents from 1685 to 1686. In 1688 came another outbreak of true influenza as described by Molyneux and Harris.

In the eighteenth century the London Bills of Mortality showed the sudden universal colds appearing on the crests of three- to six-year waves of fever, and more recent epidemiological records make it possible to trace an undulatory incidence with wavelengths ranging from one- to two-thirds of a year in pandemic times up to five or seven years in the troughs. In Sydenham's " Postcript to his Tractate on the Dropsy " we find what Sir William terms a " pearl of great price " in his unmistakable description of a cerebro-spinal epidemic of the seventeenth century. Of this new fever he says " it may be a spirituous and subtle beginning of something else, the germ perhaps of the depuratory fever now exploded, but which the plague followed." It was in fact, the precursor of the influenza of 1688, jus as the London epidemic of 1915 was the precurs of the influenza of 1918. The depuratory fever, th winter fever, the comatose fevers—all were phas of one abiding influence. Bowels, brains, and lung were successively attacked, but Sydenham mak it clear that the diarrhœa, stupor, and pneumoni were all symptomatic of one stationary fever, an that the trailers to that epidemic were comparab with the trailers to the 1661 epidemic as describe by Willis.

We can thus view the present prevalence of epidem disorders of the nervous system as an expression the downward curve of the great influenza wave 1918, and Sir William brought evidence to show tha influenza years have always inflicted special damag upon the human nervous system, and that the ev effect is most easily discernible in the age-group 0–2 The index of brain injury inflicted by the influenz epidemics of the last few centuries was found t vary from the lowest limit of less than 1/20 to th highest limit of 2/5. No epidemic disease of whic precise statistics are available causes such ravag in men of genius as those induced by the influenz group. In bygone times it was a commonplace tha sweat, influenza, and volatile typhus affected the " ge aisés," the " people of the court," in distinction t the ordinary epidemics which usually took toll the poor, the badly housed, and the ill-nourishe So ancient an authority as Fracastor, 1483–155 found an explanation for this. " From that co tagion," he says, " which spreads from one pers to another, the well-to-do are able to guard then selves, by reason of facilities at their disposal whi common people lack, but from that contagion whi is communicated through the air, the well-to-do a less able to protect themselves than the poor are, f that which may affect all alike does affect them wh are more delicate and less robust, more full-blood and more humid, on account of their luxury an quiet mode of life. The people, on the other han are more robust and less humid, as being hard worked and of more sparing way of living Sir William concluded definitely that the wid spread prevalence of influenza has constituted menace to intellectual progress. It has left its ma on many men of genius : Chopin, Sterne, Swif Carlyle, and William James, for example. Mar remarkable men have lost their lives through influenz from Shakespeare and Cromwell onwards, and th ravages of the cerebro-spinal trailers are causing much anxiety to-day. There is a tendency for m of genius not to be born during years of prevalen of influenza. This may merely reflect the increa of miscarriages and stillbirths, or may indicate son damage to the brain of infants who survive. S William Hamer urged that the " intellectual climate of to-day demands a passionate interest in gener principles as well as in stubborn facts. As Martine pointed out, " If you have the wrong instrumen the object of your search will elude you." The stre laid on bacteriological causes of disease led to a d regard of the great Sydenham's epidemiologic theories of prevalence, and to these we must retu if we are to grapple successfully with the proble The world can ill afford to lose men of genius in the difficult times, and it is conceivable that the wh future of civilisation may depend in a large mea u on a fight against that protean monster, the influenz

CONJUGAL TUBERCULOSIS.

THE vexed question of tuberculous infection betwe husband and wife, like other problems in tuberculos is made still more difficult owing to concentration major manifestations of the disease as it occurs a minority of the population with low resisti power, coupled with an almost entire neglect the manifestations of tuberculosis as it occurs in t highly resistant majority. In a recent issue of t *Journal of the American Medical Associati* (Nov. 19th, 1927), Dr. Arnold Minnig continues h observations on conjugal infection. His records cov

1888 married or widowed patients, among whom in 319 cases (16·8 per cent.), 181 female and 138 male, both consorts were found to have active tuberculosis or one to have active disease after the other had died of it. Of 104 widowed by the death of a tuberculous consort 50 (48 per cent.) had developed active tuberculosis, while 11 of the remaining 54 were "suspect." The sputum was examined in 179 of the 319 and in 94 of these tubercle bacilli were found. Dr. Minnig remarks that his figures are drawn from the poorer classes and would probably be too high for the general population; moreover, when consorts were not patients the patient's word was taken as to the mate's tuberculosis. Women, it appears, are more frequently infected than men. Adult infection is regarded as proved; the author thinks it unreasonable to suppose that a patient who has overcome a childhood infection can never again be infected from the same or any other source.

Rist and Hautefeuille[2] remark on the rarity of conjugal tuberculosis. The authors have studied 31 cases of familial infection, including 25 of conjugal tuberculosis, and draw attention to the onset of disease in the majority of cases after removal of the source of infection, usually by death. The hardships following the death of the consort and the possibility of a terminal massive infection are reviewed, but grief and the psychic depression which it causes are considered the most important factor.

A STUDY OF ENDOCRINE BALANCE.

A BIOMETRICAL study of the size relationships of the glands of internal secretion, made by Frederick S. Hammett, is embodied in a paper recently published[3] from the Wistar Institute of Anatomy and Biology at Philadelphia. This paper deals with the weights of these glands (including the thymus) in unmated albino rats; the data comprise 121 of each sex and relate to weight only so that argument from relationships between weight to relationships between functional activity must be presumptive only. Disturbing influences of age and race were avoided as far as possible by use only of rats 150 days old, all descendants of a common pair. The weights of all these glands in both sexes were found to be positively related to general body-weight (though rather less so in the female than in the male), with the single exception of the thyroid. In the case of this gland the relationship in both sexes appeared to be positive only when the thyroid was below the general average weight, and negative when it was above. There were, however, less than 40 observations in either sex of the higher thyroid weights, and these negative relations are barely significant. There were considerable differences in the degrees of association shown between the glandular weights and body-weight, and also varying values were found for the changes in the intraglandular weight associations when body-weight is or is not kept constant, but it is not made clear why factors determining the general body-weight should, as the author implies, be more essentially "genetic" than those determining the variability of the weights of single organs. The main conclusion drawn is that although specific positive correlation was found between the weights of certain pairs of glands—e.g., adrenals and thyroids, adrenals and thymus and adrenals and gonads in both sexes, also pancreas and hypophysis, and pancreas and thymus in the males, and adrenals and pancreas, and gonads and hypophysis in the females, the relation is by no means general, and the author states "that these findings are not consistent with the idea that the glands of internal secretion are to be considered as a systemically specific functionally inter-related group in the normal organism." The adrenals were found to be related in weight to more of the other glands than any other single one of these, and especially so in the females. The higher association between adrenal weight and gonad weight in the females also suggests that the adrenals are more important factors in the females than in the males. The thyroid gland was more variable in weight than any of the others, the thymus next, and the rest of definitely lower variability. The method of partial correlation was used to find the "specific" associations between each pair of glandular weights—i.e., such association as is not common to that with body-weight and weights of other glands. Partial correlation is a useful tool, but it has its limitations, and the higher the order—i.e., the more variables are eliminated—the more assumptions have to be made or tested, and the common method followed here of only investigating the linearity of the relation between the original pairs of variables and not that of subsequent pairs of deviations makes the interpretation of the final results difficult, especially when, as here, five variables are kept constant. Nor do we feel that the evidence given justifies such a deduction as that with regard to adrenal weight and hypophysis in the males "a change in association is brought about by an increase in thyroid activity which is valid and negative in direction if the fifth order coefficients are accepted as they stand." It does not seem correct when investigating the effect of enhanced thyroid activity while restricting the observations to those with thyroid glands heavier than the mean in the case of the thyroid associations, to include all observations, whatever the thyroid weight, in finding the other associations used to get the partial coefficient. In an ideal case this might not matter, but the present case is not ideal, the numbers are limited, and some of the regressions are of doubtful linearity. The value given by this method for the correlation between the weight of adrenals and of the thymus for males, keeping constant thyroid weight above the mean, and body-weight—is 0·105, but when the same coefficient is found by the method we should prefer, using in all cases only those observations with thyroid weights above the mean, we get +0·245, an entirely different result. We should not, however, attach any great importance to either of these values, as there are not enough observations to find reliable partial coefficients in this range. Our general feeling is that the mathematical analysis has been pushed somewhat mechanically a little farther than the data allow, and that for the reasons given above great caution should be exercised in interpreting the higher coefficients, and the indications given by them looked on with reserve until independently confirmed by other observations.

MENTAL BREAKDOWN IN ADOLESCENCE.

FEW cases can be more distressing than those which are nowadays labelled acute schizophrenia. A young boy or girl, usually of great promise and at the threshold of a career, suddenly passes from apparently normal adolescence into a state of apathy, excitement, or depression. The change may occur a few days before an important examination or apparently arises out of an unhappy love affair, and the anxious relatives ask immediately what is going to happen. Unfortunately, the question is very hard to answer, and the discussion on prognosis, held at the Maudsley Hospital on Feb. 14th by the Section of Psychiatry of the Royal Society of Medicine, did not give much guidance to those who are faced with such a situation. Dr. G. W. B. James admitted that many of the patients, whose chances seem best, pass slowly but steadily into a hopeless dementia, whilst those who appear unlikely to recover often emerge rapidly from a stage of psychosis and are able to return not only to their homes, but to their work. Of 14 patients whom he had followed up, all from private mental hospitals, only five had had to remain under care, and of the nine who recovered five were actually able to hold a job. To describe such cases as dementia præcox is misleading, for a state of confusion, excitement, or depression is not necessarily associated with any degeneration of the mind; and a young person who has been through such an acute phase ought not to be branded for life as a dement. Dr. Percy Smith,

speaking from his exceptionally large experience, agreed with Dr. James that at present there was no means of arriving at a satisfactory prognosis. Our ignorance in this matter comes partly from not knowing the relative ætiological importance of such factors as heredity, overwork, emotional stress, septic foci, and unhealthy environment, all of which may play their part. Dr. A. A. Petrie remarked that the examinations which appeared to precipitate the attack were usually not of an exacting standard, and suggested that the cause of the trouble was the attempt to do too much. Such attempts—perhaps fortunately for the race—are exceedingly common in the adolescent, as, indeed, are all sorts of "abnormal" behaviour. There is reason, however, for taking them seriously, and ideally speaking, the child whose progress does not seem to be satisfactory should always be under the watchful though inconspicuous care of an expert, who can distinguish true danger-signals from developmental will-o'-the-wisps.

HEALTH OF THE ROYAL AIR FORCE.

DURING 1926 the average strength of the R.A.F. was 32,985 men, which was almost the same as in the previous year, and the statistics of illness are very similar.[1] Compared with the other ranks officers suffered slightly less from disease, but very much more from accidents, of which 112 proved fatal in the Force as a whole. Two-thirds of these occurred in flying, but although the number remains large, it is decreasing in relation to the number of hours flown. The mortality from disease was low, the chief causes being pneumonia and pulmonary tuberculosis, each of which caused six deaths. A small epidemic of diphtheria occurred in the neighbourhood of Halton in Buckinghamshire, and the 1742 apprentices at the station were Schick-tested and, where necessary, immunised. No case of diphtheria developed among them, but there was a small outbreak of scarlet fever, which seemed to be milk-borne. In Iraq, whence most of the cases of dysentery were reported, 31 carriers were found among the personnel handling food. In the same country there was an increase of malaria as a result of floods, and heat-stroke caused five deaths, four of the patients having hyperpyrexia and lingering on for many days. At one time the temperature was over 120°F in the shade, and humidity was high. In Iraq 130 patients were carried by aeroplane, 82 of them in air-ambulances. Food-poisoning did not occur because, it is thought, inspection is so careful. In the selection of personnel much reliance is placed on the "flying aptitude" apparatus, which measures reaction-times, and quickly gives an estimate of the probable efficiency as an aviator of a candidate or of an officer under training. This estimate is surprisingly similar to that reached by a good instructor after his longer period of observation. Tests of this kind also help good men to improve, and are of great use in estimating the degree of recovery reached by convalescents after slight concussions, showing when they may be allowed to fly again.

[1] Health of the Royal Air Force, 1926. H.M. Stationery Office.

THE HOSPITALS OF LONDON.

IT is now becoming widely recognised, as our correspondence columns testify, that any large decisions about the relations between voluntary hospitals and public authorities will have an important influence on the future of the medical profession, and as Dr. F. N. Kay Menzies pointed out at a council meeting of the Charity Organisation Society on Feb. 13th the problems involved are far too big and important to be dealt with on purely partisan or political lines. Speaking not as the medical officer of health to the London County Council, but rather as a private individual, Dr. Menzies reviewed the situation as he sees it to-day, and brought forward cogent arguments in favour of the coöperation which he believes necessary. Although, he said, nearly 70 p cent. of the voluntary hospitals were able to pay the way in 1926, as compared with 44 per cent. i 1920, there was an admitted shortage of 12,000 bed to meet which a capital expenditure of at least 8 millio pounds would be needed, and an additional mainte ance charge of 1½ to 2 millions per annum. There wa moreover, a steady increase in demand for hospit beds, owing to the constant introduction of ne methods of diagnosis and treatment, and it w evident that the burden of providing the require accommodation was becoming too great for t voluntary hospitals to bear alone. The burden wa in fact, being shifted, for whereas at the beginning the century the public health authorities were co cerned solely with problems of communal hygien they were now undertaking more and more the trea ment of the individual. The poor-law authorities London, including the Metropolitan Asylums Boar now provided nearly 80,000 beds for the treatment the sick, and public bodies undertook out of publ funds the institutional treatment of nearly five-sixt of the sick in London. If the Minister of Healt proposals for poor-law reform came into operatio over 100,000 beds would come under the single contr of the London County Council, who would then ha eight times as many beds at their disposal as we contained in all the voluntary hospitals of London. would be absurd, said Dr. Menzies, to suppose th such a change would not affect the latter, for witho coöperation it would mean, in the end, their extinctio Fortunately such coöperation was not impossible indeed it had already begun—and he was unable understand why a thoroughly practical scheme cou not be devised, by which the voluntary hospitals a the public authorities concerned with the preventi and treatment of disease might work harmonious together.

B.C.G. IN THE LABORATORY.

A FEW weeks ago[1] we commented on some Japane investigations on the power of B.C.G. vaccine protect guinea-pigs against tuberculosis, and it interesting to find in the *British Journal of Expe mental Pathology* for February an account of simil experiments by Dr. C. C. Okell and Dr. H. J. Paris of the Wellcome Physiological Research Laboratori Their object was to repeat Prof. A. Calmette's origin observations, and the work was divided into fo experiments, in which guinea-pigs were given B.C. intravenously or subcutaneously, and were lat tested for immunity to virulent infection. A peri of 5 to 12 weeks was allowed for the development this immunity, and suitable controls were employ throughout. On the whole the results may be regard as satisfactory, and Dr. Okell and Dr. Parish say th from their experiments "it seems clear that by mea of B.C.G. guinea-pigs can be partially and in so cases completely protected from infection with a do of virulent bacilli." There is no reasonable doub they consider, that the vaccine gave rise to a significa immunity, but they are not prepared to say that as means of prophylaxis B.C.G. proved better than oth vaccines which have had their vogue in the past. T best results were obtained in the last experiment, wh a minimal infecting dose was used, and in this gro 27 per cent. of the animals were completely protecte The vaccinated guinea-pigs either showed no reco nisable sign of tuberculous infection, or else we found to have generalised tuberculosis similar that seen in the controls. The vaccine itself nev seemed to produce any of the lesions of the disea during the period of experiment, but attention drawn to a statement by S. A. Petroff, A. Branch, a W. Steenken,[2] that they were able to obtain virule "variants" from cultures of B.C.G. This sugges that the attenuated organism is capable of dangero reversion, but Dr. Okell and Dr. Parish, in view of t fact that it proved harmless in their own experimen

[1] THE LANCET, Jan. 14th, p. 92.
[2] Proc. Soc. Exp. Biol. and Med., 1927, xxv., 14.

regard it as representing "a move in the right direction as compared with the partially virulent strains with which most of the sound work of the past had been done."

AMONG 15 candidates whose names have been recommended for election as Fellows of the Royal Society are Dr. Major Greenwood, professor of epidemiology and vital statistics at the London School of Hygiene and Tropical Medicine; Dr. C. H. Browning, professor of bacteriology in the University of Glasgow; Mr. David Keilin, lecturer in biology, and Dr. G. V. Anrep, lecturer in physiology in the University of Cambridge; and Mr. S. B. Schryver, professor of biochemistry at the Imperial College of Science and Technology.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. A. Davidson is placed on the Retd. List with the rank of Surg. Capt.

To be Surg. Lts.: R. A. Graff, T. L. Cleave, G. D. J. Ball, E. S. Bolton, S. L. Lord, and W. D. M. Sim.

The following appointments have been made:—Surg. Comdrs.: L. S. Goss to *Suffolk*; T. J. O'Riordan to *Vulcan*; R. P. Ninnis to *Pembroke*, for R.N. Barracks, Chatham; and W. H. Murray to *Frobisher*, and as squadron medical officer (on transfer of flag). Surg. Lts.: J. B. Patrick to *Frobisher* and A. S. Burns to *Calliope*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. F. Shea, having attained the age fixed for compulsory retirement, retires on retd. pay and is granted the rank of Col.

Capt. W. W. S. Sharpe to be Maj.

Capt. C. H. C. Byrne to be Maj. (Prov.).

A. F. Downie to be temp. Lt.

The undermentioned to be Lts. on prob.: C. L. Day, R. T. L. Archer, D. R. W. Burbury (late Surg. Lt., R.N.V. Res.), P. J. L. Capon, P. Dwyer, K. McNeill, M. R. Burke, P. W. A. Agnew, and J. C. Gilroy.

Lts. C. L. Day and J. C. Gilroy are secd. under the provisions of Art. 205, Royal Warrant for Pay and Promotion, 1926.

TERRITORIAL ARMY.

Col. G. W. Miller vacates his appt. of A.D.M.S., 51st (Highland) Div., on completion of tenure.

Col. J. H. Hunter to be A.D.M.S., 51st (Highland) Div.

Lt.-Col. (Bt. Col.) C. L. Isaac, from the Gen. List., R.A.M.C., T.A., to be Col.

Lt. Col. A. R. Moodie, M.B., to be Bt. Col.

Lt.-Col. F. T. Rees, from Gen. List., R.A.M.C., T.A. (Res. of Off., to be Lt.-Col. and to comd. the 158th (Welsh) Fd. Amb., vice Lt.-Col. (Bt. Col.) C. L. Isaac.

Maj. H. G. F. Dawson, having attained the age limit, is retd. and retains his rank with permission to wear the prescribed uniform.

Maj. S. R. Gibbs resigns his commn. and retains his rank with permission to wear the prescribed uniform.

Capt. (Bt. Maj.) G. H. R. Gibson to be Maj.

Hygiene Companies: F. W. Bury to be Lt.

ROYAL AIR FORCE.

Flight Lts. E. Thompson and N. I. Smith are granted permanent commissions in the rank stated.

The undermentioned are granted short service commissions in the rank of Flying Officer for three years on the Active List: J. Kemp, B. B. Kennedy, J. J. MacAndrews, R. F. MacLatchy, J. B. Murphy, J. C. Neely, F. A. O'Connor, M. O'Connor, and J. J. Quinlan.

DEATHS IN THE SERVICES.

Colonel Robert Hall Forman, A.M.S., retired, who died in London on Feb. 16th, was born in 1854 and qualified with the L.R.C.P. Edin., and L.R.F.P.S. G. in 1877. In the following year he graduated in medicine and surgery at the University of Glasgow, having previously obtained a commission as surgeon in the Turkish Army with which he served in the Russo-Turkish War. He joined the A.M.S. in 1880 and was employed both at home and in India. After 31 years' service he retired, under the age clause, in 1911, but was recalled for duty during the late war, when he was inspecting officer on the staff of General Sir C. Francis Lloyd. Colonel Forman was a popular personality and a keen Freemason, and in his younger days was a powerful Rugby forward and captain of his University XV.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXIV.

THE TREATMENT OF INFANTILE CEREBRAL PARALYSES.

THE treatment of infantile spastic palsies is frequently approached with an attitude of extreme pessimism which is probably unmerited. This is largely due to the existence of a considerable number of cases in which the prognosis is hopeless, and for which no effective treatment is possible. Nevertheless a large number also exist in whom there is a possibility of obtaining an extremely good result, provided that an appropriate line of treatment is adopted at an early age. It is therefore most important that the factors upon which the prognosis depends shall be clearly recognised.

The Outlook of Treatment.

Certain features may be indicated which place the case beyond the reach of effective treatment.

(1) *Evidence that the disease is progressive.*—A small minority of them are manifestations of some condition such as amaurotic family idiocy, or combined degeneration of cortico-spinal and other tracts.

(2) *Presence of a profound degree of mental defect.*—Caution must be observed in making this diagnosis. It must be remembered that mental *retardation* alone is often present in these children, and that under favourable conditions considerable progress may be made in later years. The diagnosis of mental defect in the first three years of life is extremely difficult and uncertain, when the picture is complicated by a coexisting motor disability. This significance should never be attributed to inability to talk; for practical purposes the symptom which renders them unsuitable for treatment is apathy, lack of desire to make movements or handle objects.

(3) *Persistent occurrence of fits.*—A history of occasional fits in infancy is often obtained in children who have made excellent progress. But in those who suffer from repeated convulsions persisting through the second year, the development of some degree of dementia is the rule; it is commonly associated with an attitude of negativism which presents an equally insuperable barrier to treatment.

Two other types of case may be recognised, in which the prognosis is decidedly unfavourable, though an attempt at treatment should be made, as some improvement is possible: (1) in which choreiform or athetoid movements are present; (2) in which a high degree of generalised muscular rigidity is present, sufficient to render active movement impossible. In this type nothing can be accomplished unless the spasm can be reduced by surgical means. This condition is not often found in cases which have received early treatment.

Excluding the patients who exhibit these symptoms, there remains a large number—the majority, I believe, of those who survive the first year of life—in whom the prognosis is by no means so gloomy, and whose future depends to a very great extent on the treatment and management which they receive. It is of the greatest importance that this shall be started during the first two years; when this is done, one may confidently expect that almost all of them will be able to walk and make good use of their hands, while a large proportion of them will attain a degree of improvement which hardly falls short of complete recovery of function.

Prophylaxis.

To cases of primary neuronic degeneration this does not apply, but the question may arise as to whether spastic paralysis may be averted in an infant whose condition at birth suggests intracranial hæmorrhage. A measure which inevitably suggests itself is lumbar

puncture; opinion is divided on its merits and demerits. It has been advocated from various motives; to confirm the diagnosis, to relieve the intracranial pressure, and to miminise the effects of the hæmorrhage on the cortex and subcortical areas. In practice it usually leads to disappointment in all of these expectations. Moreover, the disturbance occasioned by the operation involves an element of danger to the infant. The safest prophylactic routine in such cases is to keep the infant at complete rest, avoiding all manipulation, and feeding from a medicine dropper to obviate the effort of sucking.

General Considerations of Treatment.

The fact must be borne in mind that the defect is in the brain and not in the limb, and that treatment must be directed primarily towards the former. No form of passive treatment appears to be effective in preventing the onset of spasm and contracture, whereas some forms certainly aggravate it. Active movements performed by the child—whether purely reflex or to some extent "volitional" is immaterial—are the only agents which seem to produce a really lasting effect on the tone and functional activity of the affected limbs. The exact process by which this improvement is brought about is not clear. It is impossible to expect development of function in the neurones which have been injured, or have degenerated. The possibility that new synaptic connexions may be formed, that other neurones may acquire the functions which the (as yet undeveloped) pyramidal tracts were intended to subserve, is an entirely hypothetical one, yet it is suggested by the remarkable recovery of function in the child as compared with the adult. The effect exerted by active movement in reducing spasm is probably accounted for by the inhibitory impulses (to antagonistic muscles) which are an essential component of the innervation of voluntary and reflex movement. Relative integrity of the cortical areas may be necessary for this improvement; in imbecile children active movement has been found to aggravate spasm.

Cerebral palsies are not always recognised at birth. It is common for cases of diplegia to be brought for advice in the second year, owing to the parent's disappointment at their inability to stand. The cortico-spinal tracts play so small a part in the infant's activity that there is little obvious abnormality in the earlier months. Hemiplegic cases tend to attract attention somewhat earlier, as the asymmetry is noticed by the parents. If at this stage of development, while behaviour is still to some extent controlled by infra-cortical centres, the child can be assisted to make habitual use of the affected muscles, contracture does not usually develop, and the results of the treatment are often remarkably satisfactory.

Measures directed to the limb.—The use of warm baths, or limb baths in older children, is at any rate rational, as some degree of relaxation takes place under the influence of heat. Massage and passive movements are frequently employed; I have never observed any good effect from them, but they are innocuous and may satisfy a parent who is clamouring for "something to be done." Unfortunately the parents' desires are so often fixed on the one form of treatment that is absolutely contra-indicated and definitely harmful—i.e., electrical stimulation. It is most important to warn the parents at the start that this must never be permitted, and to explain to them that the muscles are already contracting too much, and that electricity will only make them contract more. I believe that the existence of so many permanently spastic children, which is responsible for the pessimism with which these cases are so often regarded, is due very largely to the widespread prevalence of this practice.

Methods of Initiating and Assisting Active Movement.

(1) *During infancy.*—The number and extent of the motor activities developed by an infant are influenced considerably by its habitual position. While the infant lies on its back, movements are comparatively few and aimless; as soon as it sits up, new and mo complicated ones develop with remarkable rapidit A very constant symptom of cerebral palsy is delay sitting, standing, and other "milestones" of infanc and the acquisition of movements is greatly restrict thereby. The first step in the treatment is to get t child into a sitting posture, and the result of this alo is often very striking. In many cases it can be do by simply propping the child with pillows. In othe more often in the second year, spasm of the erect spinæ and glutei renders it difficult to keep the ba and thighs flexed. The child may then be place in a baby's chair with a sliding bar in front. small pillow on the abdomen receives the pressu of the bar and maintains a position of flexion. In surprisingly short time the muscles of the trunk adju themselves to the new attitude, and the child enabled to practise a number of new activities and w handle objects which he took little interest in while a recumbent position. Similar attempts should made at a later stage to combat the retardation crawling and standing.

In *hemiplegic* infants, as soon as an increase of mot activity has been attained by these means, steps shou be taken to develop the motor paths for the paret limb. There is only one possible way of making a infant use an arm that is stiffer than its fellow, a that is to immobilise the sound one. The norm limb is bandaged to the chest for about half the da and objects of interest are placed within reach of t paretic hand. If this is done in the early months life the maximum result will be obtained, but th procedure is the essential therapeutic measure in t treatment of a residual hemiplegia at any age. T foot should be relieved of the weight of clothe Occasionally a light splint is required at night, but it usually best to avoid these during the first two yea

(2) *During later years.*—The immediate object is get the child walking and to avoid any measures whi will necessitate remaining in bed. At the stage wh the child is just unable to stand alone, a most usef apparatus consists of a wheeled frame with crut supports which are adjusted to the axilla. After a fe weeks of practise in the frame, the child is often ab to support the weight of the body, but still fin difficulty in maintaining its balance. At this sta he can usually obtain sufficient support from t handle of a doll's perambulator in the front end which some weights are placed. The first attemp at walking alone should be made on grass, so that t sufferer may not be deterred by painful tumbles. horse-tricycle may also be of assistance in re-educati a paraplegic child, particularly if adductor spasm present.

For *hemiplegic* children the immobilisation of t sound arm should be persisted in for part of the da as long as there is a tendency to use that arm alon At other times exercises should be devised and to provided which encourage the use of symmetric bilateral movements. The best of these is furnish by a wheel-barrow, fully loaded, which the child encouraged to make use of without spilling the content

The range of passive movements must always kept under observation. If this is restricted actual contracture of any muscle-group, no goo result can be obtained by attempts at active mov ment, and the assistance of the surgeon is require One particular movement—supination—is especiall difficult to establish, and often becomes restricted in hemiplegic child in whom all other movements ha been successfully developed. If the pronator spas is dealt with by some measure such as Stoffel operation, attempts at active movement may resumed within a few days.

The limited experience which I have had of t results of sympathetic ramisectomy have not led m to regard it as a justifiable measure.

MEDICINE AND THE LAW.

Charge of Negligence against Mental Hospital.

Lieut.-Commander G. H. Drummond, V.C., R.N.V.R., has recovered £500 damages in an action for negligence and breach of contract against the Wonford House Hospital, Exeter. Mrs. Drummond, his wife, has also been awarded £120 damages. The plaintiffs alleged that Mrs. Drummond in April, 1926, after the birth of her third child, became extremely ill. Dr. Grant Wilson, of Sidmouth, finding her to have delusions of persecution and all the symptoms of acute puerperal melancholia, telephoned to the Wonford House Hospital at Exeter (an institution with accommodation for some 140 patients) and gave Dr. W. B. Morton, the doctor then in charge of the hospital, who has since died, information about Mrs. Drummond's condition. Dr. Wilson suggested to Dr. Morton that she should enter the hospital as a voluntary patient but, if this was not regarded as safe, he undertook to go over from Sidmouth to Exeter and certify her. During Mrs. Drummond's first night in the hospital and during the following day she was watched constantly. But on the second night, at 4 A.M., when no nurse was present, she broke the glass of a window and forced herself through an aperture less than 10 inches square. She fell and struck an iron balustrade, breaking her arm and her jaw in two places. These injuries, said the plaintiffs, were the result of her having been left unattended. A nurse or attendant should have heard the smashing of the glass and would have been in time to prevent the patient from completing the feat of working her way through the aperture. Owing to the fact that Dr. Morton was no longer available as a witness there was naturally some doubt as to exactly what information the hospital had received regarding Mrs. Drummond before her admission. For the defendants it was urged that there was no evidence of Dr. Morton being aware that she had shown such grave symptoms; no one would have dreamt that a patient, whether suicidal or not, could crawl through such a tiny opening. Dr. J. G. P. Phillips, physician-superintendent of the Bethlem Royal Hospital (called by the defendants) thought it quite reasonable to have removed the nurse from Mrs. Drummond's room on the second night if—as was stated—the patient had complained that the nurse's presence prevented her sleeping. He considered it quite proper to have admitted her as a voluntary patient, and he pointed out that symptoms of depression and insomnia are often encountered without being readily diagnosed as melancholic. The plaintiffs replied that Mrs. Drummond could not have been admitted to hospital for mere sleeplessness, nor was she placed in a room suitable for a suicidal patient if left unattended. The jury, in awarding damages as already stated, also awarded the hospital £22 10*s.* on a counter-claim for fees. These fees the plaintiffs had refused to pay as being unearned in the circumstances.

The case illustrates the familiar fact that, though the telephone is properly used in an urgent case—as here, for instance, in arranging the prompt admission of a patient to hospital—it may prove an uncertain substitute for a detailed written report if such a record is for any purpose afterwards required.

Unsound Meat Exposed for Sale.

Vigilance in the inspection of meat unfit for human food continues to result in smart penalties. A fine of £50 (with an order to pay a further £50 towards the costs of the prosecution) was imposed lately at the Central Criminal Court upon a Hampshire farmer and cattle-dealer in respect of beef sent to London last November. The meat (two sides of beef from one cow) was sent to a firm which sells on commission. The firm's practice was to have all such meat inspected before exposing it for sale. The inspector found the meat tuberculous; he seized it and obtained the order of a justice of the peace for its destruction. The defendant farmer denied all knowledge of there being anything wrong with the meat, but the Common Serjeant pointed out that knowledge or ignorance was immaterial if the meat deposited for sale was in fact unfit for human food. The defendant also took the point that the beef was not deposited for sale but merely deposited for inspection; he said this meat was never exposed for sale. If such a defence were to provide a loophole the law would certainly require alteration. Evidently, however, the jury, in finding the farmer guilty, were satisfied that the meat had in fact been deposited for sale.

A Legal View of Motoring Offences.

Members of the medical profession from time to time succumb to the accident of a conviction for some motoring offence. They may be interested in a recent case in which the High Court decided that such convictions are not to be taken too seriously. A commercial traveller was employed by a firm of perambulator and toy manufacturers in Yorkshire on a seven months' agreement at certain terms in respect of commission and renewal. A month after the contract was made, the commercial traveller became involved in a collision at night and the Sussex magistrates came to the conclusion that he had been driving on the wrong side of the road. They convicted him of driving to the common danger, fined him £10, endorsed his licence, and suspended it for three months. His employers regarded this as misconduct entitling them to terminate his contract of employment. They further said that before the contract was made he had been convicted of being drunk when in charge of a motor-car, had been fined, had had his licence suspended, and had been sentenced to a month's imprisonment in the second division for driving in a manner dangerous to the public. They also relied upon yet another conviction when he had been fined £3 for exceeding the speed limit. These convictions, they said, were material facts which the commercial traveller ought to have disclosed when applying for employment; the concealment, they argued, entitled them to put an end to the contract. Mr. Justice Finlay held that the non-disclosure did not justify the employers in repudiating the contract. In contracts of insurance there is an obligation to disclose all material facts, but this contract was not of that nature. The commercial traveller's convictions for motoring offences were not a ground for terminating the contract; if he had to use a motor-car in the course of his employment he could get someone else to drive it. The leading case on the subject is Fletcher *v.* Knell, wherein it was decided (in 1873) that there was no right to dismiss a governess merely because she had not disclosed the fact that she was a divorcee. The commercial traveller's convictions had not put it out of his power to perform his duties upon his employer's business. The court, however, made it perfectly clear that if it were of the essence of a contract of employment that the employee had to drive a motor-car, motoring convictions might be material matters which must be disclosed. Thus, if a man applies for a post as a doctor's chauffeur, he must not conceal the facts and consequences of his infringements of the motoring laws.

Action by Mrs. De Freville.

The proceedings taken by Mrs. De Freville last year against Dr. Dill for negligence in his examination of her are recalled by a further action which she lately brought at Gloucester Assizes against her father-in-law, the Rev. F. P. De Freville, of Oakridge Vicarage, near Stroud. It will be remembered that, after something of a scene at the vicarage, Dr. Dill, the family doctor, was summoned and signed the certificate upon which Mrs. De Freville was sent to an asylum. Two days later she was discharged, being adjudged sane, and she was subsequently awarded £50 damages by a jury against Dr. Dill. She complained that she

was forcibly detained at the vicarage for five hours while the arrival of Dr. Dill was awaited and that, when she sought to leave the house, the vicar stood with his back to the door. Her recent action against the vicar thus took the form of a claim for damages for what the law calls false imprisonment. It was stated on her behalf that she was treated as a pauper patient at the asylum and had been subjected to an ignominious experience. Giving evidence herself, Mrs. De Freville denied that, on the occasion when Dr. Dill was sent for, she was abnormally excited or that she raved or threatened to kill anyone. The defendant described what had occurred. He had himself been struck in the eye by the plaintiff who referred to him in blasphemous language; there was no imprisonment; there was never anything to prevent her walking into the garden; Dr. Dill had been called in because she was in such a violent state. She broke a window, said the vicar, and knocked his daughter's spectacles off. He had been unaware that she was to be certified as a pauper lunatic. While another member of the family was giving further evidence in corroboration of that of the vicar the jury stopped the case. They returned a verdict for the defendant and Mrs. De Freville was ordered to pay costs on all her claims.

Clergyman's Mail Order Business in Noxious Drugs.

The remarkable facts proved at the trial and conviction of the Rev. Francis Bacon at the Central Criminal Court speak for themselves. They may open the eyes of the public to the traffic in abortifacients conducted by means of newspaper advertisements and to the abuse of the prefix "Doctor." Bacon was charged with conspiring with one Annie Bolton, a clerk, and with other persons unknown to solicit and incite women who might deal with them to administer to themselves noxious things and to use instruments and other means with intent to procure miscarriage; also, with conspiring to supply noxious things to women knowing they were to be used for a similar purpose. There were further counts in the indictment charging actual supply of noxious things in specific instances. The case opened by the prosecution was that, though there might be no drug which could be described as a certain abortifacient, there were several drugs which, if taken in too large quantities or too frequently, were likely to cause miscarriage. It was contended that the drugs advertised by Bacon as "Dr. Hannah Brown's treatment" were of this nature—"noxious" because likely to be injurious to a pregnant woman in that they might produce miscarriage. It was further contended that the defendants (as documents used in the course of their business indicated) were aware of the nature of the drugs. Lastly, although it was not suggested that in every case the drugs were supplied to a pregnant woman, it was suggested that the defendants sent the drugs to any woman who would pay for them and that their correspondence showed that in many instances they knew that the women were in a condition of pregnancy. The defence was that, if the drugs were so sent to expectant mothers, it was contrary to instructions. Annie Bolton, who had evidently played a subordinate part in the conspiracy, admitted in cross-examination that the directions to recipients that the drugs were not to be used in cases of pregnancy were mere pretence. After her evidence her counsel withdrew her plea of "Not guilty." She pleaded "guilty" and was eventually sentenced to six months' imprisonment in the second division. Bacon maintained his innocence in the witness-box by what the Recorder afterwards described as perjury. It appeared that he had used the names of Dr. Howard Baron, Dr. Mary Lane, and Dr. Hannah Brown. There was a suggestion that Hannah Brown held a doctorate of philosophy. It was also stated for the defendant that he had been given the degrees of LL.D. and D.D. during visits to Canada. This grant, which was not further explained, was apparently his excuse for describing himself as a doctor when selling drugs to women who might well be unaware of the nice distinctions in university faculties. He justified this procedure as being consistent with commercial morality—a claim which, coming from a minister of the Church of England was described by the Recorder as despicable, deplorable, and contemptible. "To make money," said Sir Ernest Wild, "you have preyed upon the agony of poor expectant mothers and jeopardised their health. Taking into account a statement of the value of the defendant's religious work in the East End, the Recorder passed a sentence of 15 months' imprisonment in the second division, hoping that the case would be a warning to all persons concerned in this pernicious traffic.

Apparently the advertisements had been so worded as not to arouse the suspicions of the newspapers which published them. Sir Travers Humphreys, in opening the case, observed that the "Dr. Hannah Brown Treatment No. 1" cost 9¼*d.*; there was 1s. for the Government stamp on it, and it was sold for 5*s.* The "No. 2 Treatment" cost 1*s.* 7½*d.* and was sold for £2 2*s.* When the summons was served upon him Bacon said the drugs were merely strong aperients and were obtained from a reputable firm.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Legislation against Venereal Disease.

THE Edinburgh Corporation have now prepared a Bill providing for the compulsory treatment of venereal disease, and it seems likely that this Bill will go forward to a second reading and be considered in due course by a Select Committee of the House of Commons. The policy it embodies is explained in an official statement which points out that schemes against venereal disease are not yielding results commensurate with the expenditure; that the purely voluntary system, which has received an adequate and indeed an exhaustive trial, has proved ineffective, and that it is urgently necessary to test a system of compulsory treatment. All that is now asked is permission to try the new policy for an experimental period of five years, but the corporation are satisfied that its disadvantages will be trifling compared with those of the present system, under which the total number of persons not completing treatment in five years was 5129, making a yearly average of 1026. Of these defaulters, it is stated, at least 524 were suffering from contagious disease, while the remainder must be regarded as potential sources of infective disease besides being in a condition dangerous to themselves. "That there should be in each year an average of over 1000 cases of possible infective disease which are known to the public health authority, and that the public health authority should be powerless to deal with these cases is far from satisfactory when viewed from the public health aspect from preventable disease. As a result of so many cases of venereal disease failing to complete their cure, the local authority is expending very considerable sums of money without adequate return."

Although the proposals for compulsory treatment are put forward only by Edinburgh, other large local authorities in Scotland have indicated general sympathy with the Bill. On this subject there is a decided cleavage between opinion in Scotland and opinion in England, as has been obvious for two or three years. For some years the attitude of the local authorities has been hardening towards more stringent control, and it appears that Glasgow and the larger authorities in the neighbourhood are pushing forward a project for much more extended powers. In Edinburgh opinion is very much divided among the women's associations, and some of these have been in conference with the Bill's promoters. The corporation are anxious to carry all sections of public opinion along with them and, in the documents circulated, they make a reasoned reply to objectors. They claim to be acting in the spirit of the Trevethin Report, particularly in asking powers only for an experimental period of five years. In essence the Bill is no great advance on the provisions of the Public Health (Scotland Act, 1897, which, at least in words, contain

ıll provision both for entry, examination, and treatıent. A somewhat new point is the stress put upon compulsory treatment." From the nature of the rovision for carrying these powers into effect, it ›oks as if the "treatment" is to be regarded simply s a method of prevention, and not to be taken merely y itself. The general principle of the Public Health cts is, of course, that every infected person should ake proper precaution against spreading infection; ut it may be argued that "treatment" and isolaon are alternative or complementary methods of revention.

If the Bill goes to a second reading, and is referred) a Select Committee, there ought to be a first-class ebate on all these issues. Undoubtedly the atmoohere has changed considerably since the Royal ommission reported, and all great local authorities ave had thousands of cases through their hands and ow understand better the limitations of the venereal isease regulations. Nearly every aspect of the ıbject, both medical and social, has been discussed gain and again in print and in conference, and the me seems appropriate for a full-dress debate in the ouse of Commons. Meanwhile it should be said ıat the Edinburgh clinic has, from the beginning, een one of the most successful in the kingdom.

A Fee-paying Glasgow Hospital.

The governors of Victoria Infirmary, Glasgow, ropose to admit patients on payment of an inclusive e of £6 6*s.* per week, subject after a few weeks to duction to mere maintenance charges. This would e sufficient to cover the cost of establishment charges ıd nursing, together with a modified fee to the ırgeons who perform the operations. For these ırposes a separate annexe will be built, with access the present operating theatres. None of the present ard accommodation will be used for pay patients. ne chairman has indicated that there is no intention interfering with the function of the private nursing mes and that means will be taken to restrict the ork to those who feel the "private home" fees to be financial burden. The experiment is a sign of the mes and its development will be watched with terest. A somewhat similar extension by the asgow Royal Infirmary is in progress, but I underand that this is restricted to provision for maternity ıd gynæcological work.

Steel Houses.

A little time ago Lord Weir offered to Glasgow rporation the stock and certain accessories at the ırdonald Factory on condition that the corporation ould erect 5000 steel houses. The corporation has t accepted the offer. The reasons are probably ixed, but it is now the case that a brick house of uivalent accommodation can be built more cheaply an a Weir steel house. It is to be regretted that rd Weir's experiment in auxiliary housing has never tained a broad enough canvass; but the 2000 eady erected by the National Housing Company ll give sufficient information to test the endurance d comfort of such a building medium. Probably ong the many types of experimental materials el will hold its own.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Meat Inspection in Cork.

IT is a sign of the new spirit in public health ministration in Ireland that Dr. J. D. Carroll, the cently appointed medical officer of health for Cork, endeavouring to establish a system of meat inspecn in that city. In a recent report to the borough mmissioner he recommends a stringent revise of -laws, by which the sale of meat before inspection uld be prohibited. He points out that at present e only place where meat can be inspected is the tual stall or place of sale. To inspect the stalls or ops would require a greatly increased staff. Moreer the inspection would be faulty, because a carcass should be examined as a whole and not after cutting up. The public health authorities have no power to supervise slaughter-houses outside the city boundary, nor to insist on notice being given of the time of slaughtering in the slaughter-houses within the city. Dr. Carroll's suggestion is that all meat intended for sale in the city should be brought to a central depôt for inspection.

Deputation to the Minister for Local Government and Public Health.

The Minister for Local Government and Public Health, Mr. Richard Mulcahy, accompanied by Dr. E. F. Stephenson, chief medical officer, and other officials, recently received a deputation representing the Irish Medical Committee. In the first place the deputation pointed out the inadequacy of the salaries paid to dispensary medical officers particularly in the counties of Mayo and Longford, and asked the Minister to regulate the salaries in these counties on the basis of the scales paid in other counties. He promised to explore the situation fully to ascertain the best way of dealing with the problem, but was unwilling at present to fix the salaries by sealed orders. Attention was drawn by the deputation to the transfer of medical officers by local authorities, and it was urged that transfer should be treated as promotion, not as an exercise of patronage. Seniority, meritorious service, and post-graduate experience should be the determining factors. Attention was also drawn to difficulties not infrequently placed in the way of medical officers applying for leave, and in reply the policy of the department to afford all reasonable facilities was explained. Questions relating to county hospitals were discussed; it was submitted that the salaries of county hospital surgeons were inadequate, and scales from £800 to £1200 a year were suggested. The Minister promised that individual cases would be considered as they arose. The deputation were opposed to any system of payment which would render it part of the duty of the surgeon to give treatment to paying patients. They expressed approval of the terms of the draft regulations dealing with the admission of paying patients to hospitals, and asked that they should be applied to all county hospitals. It was stated that at present many persons who were able to pay full costs of maintenance, treatment, and medical attendance were being treated free in the county hospitals. The Minister promised to inquire into this matter. He further stated that the delay in appointing medical officers of health in certain counties was not being overlooked, and that the matter would be pressed forward. He expressed his sympathy with the request put forward that the Government should consider the provision of funds for medical research.

Certification of Insured Persons.

The proposal of the National Health Insurance Commissioners to alter the present method of distributing the funds available for payment for the certification of insured persons is causing much adverse comment in the profession. At present the funds are distributed into pools for each dispensary district according to the number of insured living in the district. The Commissioners propose to substitute a county pool for a dispensary district pool. The case is made that the small pooling area requires complicated and troublesome book-keeping, which adds materially to the cost of administration, and that there are the widest discrepancies between the rate of payment per certificate in different but similar areas. In reply, it is pointed out that the larger the pool area the more difficult it is to place any check on careless certifying. With a dispensary area pool in country areas most of the certifying in each area is done by the dispensary medical officer, who is, therefore, under no temptation to issue certificates laxly, but with a county pool he is tempted to be less careful. It is unlikely that the change proposed by the Commissioners will bring about any improvement in the efficacy of certification, though it will cause a trivial saving in administrative expense.

Correspondence.

"Audi alteram partem."

"INCIDENCE OF THE MINOR PSYCHOSES."

To the Editor of THE LANCET.

SIR,—It is to be hoped that Dr. Millais Culpin's valuable paper on this subject in your issue of Feb. 4th will not speedily pass into limbo. That nearly 50 per cent. of the working population as tested by his samples should suffer from psychoneurotic symptoms, that in a group, where special care had been taken to exclude the temperamentally unfit 18 per cent. should have these symptoms fairly marked, must provide material for thought. And it is to be noted that this was a *working* population, not one which needed to be told to "pull itself together and get on with it." These people were already doing so; clearly many of them thought that their condition was one of health, and were unaware that relief was possible for them.

There are many points of interest in the paper but I should like to call attention to one or two. First, there is clearly shown a distinction between psychoneurotic illness and psychoneurotic symptoms. In the laundry which Dr. Culpin investigated illness was rare, but people with symptoms were numerous. Illness was not common because care was taken of these workers. Those who were present at the meeting where the paper was read cannot have failed to be impressed by the enthusiasm of the employer at this particular workshop; one felt that everything that interest in the welfare of the people could do was being attended to; one felt that here occupational therapy was being carried on at its best, and that the results were as good as could possibly be obtained from such a method. But probably with a simple psychotherapy many of these patients could have been made well—i.e., comfortable instead of uncomfortable. A second point which Dr. Culpin emphasises and which requires much taking to heart is that it is easy to change "neurasthenia" into "anæmia" and "indigestion" if the real condition is merely frowned on and not treated. Those who had the privilege of studying the war cases will remember the odd synonyms which obtained a footing in those times, myalgia, D.A.H., &c.

On several grounds, however, I cannot agree with Dr. Culpin that we should term these conditions "minor psychoses." Whatever be the origin of the word psychosis it has come to mean insanity in the minds of almost everybody; patients want to know what the word means, and we cannot in truth tell them anything else. I should not care to say to them that they were suffering from minor madness. It will be said that insanity is a legal term, but if it were it should be capable of definition. It is not fair to saddle the lawyers with this responsibility. The idea of insanity is one in general use. We ourselves act on it continually; it is usually on our initiative that patients are placed in the legal status of being insane. The condition is hard to define but on the whole we know when we are dealing with it, just as it is difficult to make a distinction in words between an animal and a vegetable, but the two conceptions present no practical difficulty in their differentiation. Neither do I like the word "minor," for though these particular people were not very ill, their condition may if neglected give rise to as much suffering as any disease we know of. This minor malady may easily be a graver disease than a mild manic-depressive psychosis, which, however, is always classified as a major psychosis. If some such expression is to be used, surely the adjective should be "benign." A fibroid of the uterus may be a graver disease than an epithelioma of the lip; we therefore do not speak of the non-malignant tumours as minor, but as benign.

To my mind these psychoneurotic patients are much more allied to normal people than they are to psychotic patients. What Dr. Culpin was studying was the incidence of emotional reactions, which after all a present to some extent in nearly everybody. It a question of degree, of the amount of discomfo which they cause whether we shall say that t patient has an illness or not Dr. Johnson touch posts, and was therefore a subject of the obsessiv compulsive neurosis; there are few whose freedo from acrophobia would enable them to stand on t top of a factory chimney. Fear of the dark childhood was inquired about; surely it is universa but I may here be doing Dr. Culpin an injustic He may have used this question only to lead up the further one, is it present now? Even so, it quite common in people who are not even benign psychotic. It is when these normal reactions becon excessive that we call them illness. When they a so frequent that absence from work becomes imperati we have certainly passed into that state. Wh less frequent they may constitute a danger. There a point short of their putting an end to work alt gether where they clearly indicate that the individu is not adapting himself to his environment, where som thing should be done; but it is not likely that they a quite absent in anyone, though it might take caref investigation in many to establish their presence.

It may be thought that if there is truth in the remarks, then there is an end to the value of D Culpin's research. This is not so. In a very sho examination Dr. Culpin elicited these symptoms wi great ease. It would have taken much longer observ tion to have done this had he not been getting ne danger-points. Now the psychotic is in a differe state. However severe a psychoneurosis, the patie can be reasoned with on the lines on which we ordinarily reason. He will respond and argue, an fortunately, he will sometimes even agree with us accordance with the logic we all use. However mi a psychosis this cannot be done so far as the psycho is concerned. The psychoneurotic is sure of nothi and his reasoning can be upset; the psychotic always sure of certain things, and where he is su he cannot be upset.

It is not quite fair perhaps to revert to wh happened at the debate when the paper was discusse for nothing of it occurs in Dr. Culpin's publish paper; but I shall venture to rely on his generosi and do so. Dr. Culpin said on that occasion that could not see why a man who had an irrational bel that he was being persecuted was said to be sufferi from a psychosis, while one who had an irratio fear which prevented him crossing an open field w said to be suffering from a psychoneurosis. T difference is a matter of clinical experience. The fi man will almost certainly maintain against cle proof that he is right, and nothing will shake hi *Our* logic will avail nothing. If the whole world hol otherwise the whole world will be wrong. The oth man will in the first place agree with us that his fe is irrational; secondly, if it can be shown that h fear really represents something else—and t demonstration will be within logic—he will like accept this idea, and by such logical steps, when has been shown what it was all about, he will in ma instances lose his fear altogether.

I am, Sir, yours faithfully,

T. A. ROSS.

Cassel Hospital for Functional Nervous Disorders, Penshurst, Kent, Feb. 13th, 1928.

THE PRESENT POSITION OF THE VOLUNTARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—Being a firm believer in the voluntary hospital system I have followed with interest t recent correspondence in your journal under th heading; it has been instructive and, I think, h come opportunely. I wish, however, to point o that the coöperation advocated by Dr. Graha Little and Mr. Spencer is not the only change need in our voluntary system as at present carried ou It has other serious defects that require to be remedi

ithout delay if it is to emerge successfully from the erious crisis through which it is now passing. I say serious" advisedly, because it has to be recognised hat nationalisation of our hospitals has the support ot only of some of our profession and of many of the eneral public, but also, it would appear, of the abour Party, whose creed is that all hospitals should e under State control. It is in this fact that the hief danger to the voluntary hospital system lies; feel that this is not being sufficiently realised, and e should grasp the facts which are relied on for stifying the changes advocated.

On one occasion, when I had to defend the voluntary ospital system on a public platform, my opponent eing one of our own profession, I had clearly put efore me the arguments on which the advocates of ationalisation rely. Put briefly, the position taken p was that the voluntary hospital system has the ree following main defects: (1) It cannot supply ne money necessary to meet the expenses of the pkeep of the civilian hospitals; (2) the hospital ccommodation furnished is not sufficient for the equirements of the community; (3) coöperation etween the different classes of hospitals and the oluntary hospitals themselves is absent. It cannot e denied that our voluntary hospital system as at resent carried on has these three defects, and had admitted so much, at the same time pointing ut that the defects could be remedied without aving recourse to nationalisation. I do not propose, this communication, to put forward the changes our hospital system that I would advocate in onnexion with them, but I wish to point out that ne supporters of nationalisation of our hospitals ave grounds for asserting that the defects above entioned exist, and that they may be justly regarded s serious drawbacks to the voluntary system. This, think, the supporters of the voluntary system have ot fully realised.

Taking first the monetary question, great reliance placed on the view that "the voluntary system is owing in strength year by year" (see the Cave eport), and that appeals are always generously sponded to. No doubt this is so, but the fact mains that our newspaper columns contain such aily appeals for help, and the returns in Burdett's Hospitals and Charities" indicate that the financial osition of the voluntary system is far from satis- ctory. The workmen's contributions form a very gnificant departure and is one that will make itself rofoundly felt, for, under it, our civilian hospitals ill be largely maintained by the working classes, and ot so much so by the rich. This is as it should be nd is welcomed by many as a very praiseworthy ature (which undoubtedly it is), but a little con- deration will show that it must be safeguarded, herwise it will be used as an argument against the oluntary system, and it will be quoted as showing at it is the money of the working classes that has ven stability to the financial side of the voluntary ospitals. A Labour Party in power would use the ct as a strong argument in favour of the nationalisa- on of our hospitals. Representation on the boards management have been granted in respect of these ntributions, and they, I think, cannot be justified, r these moneys are not subscriptions to the hospitals they are deducted from the workmen's pay, being some cases supplemented by the employers. They ould rather be placed under contributions for aintenance, seeing that value is more than received r them in the shape of the medical and surgical ill that they ensure. In my opinion, these sub- riptions do not qualify for representation on the oards of management, any more than daily travelling a certain railway entitles passengers to the right being qualified as shareholders.

Coming now to the complaint that the voluntary ospitals do not furnish sufficient accommodation r the needs of the community, there is no doubt at this deficiency acts to the detriment of the oluntary system. It has been used as an argument r increased public support, in view of the great amount of work that the voluntary hospitals are called upon to do, but it is equally certain that it can be detrimental, for the long waiting-lists that are the outcome of it are relied on as proof of the want of beds. The fact is that the deficiency arises from not laying down definitely the class of patients that are to be admitted, thus keeping an open door through which, naturally, everyone seeks entrance. There is no doubt that the voluntary hospitals should confine themselves to the wants of the artisan class, leaving the really necessitous poor to the poor-law hospitals, the needs of the middle class of society (which are very clamant) being met either by paying-beds in the hospitals, or, preferably, by inexpensive nursing homes, where, for a moderate inclusive charge, they can obtain reliable "medical lodgings" and be sure of a healthy environment, of good nursing, of proper food, the use of a proper operating theatre, if needed, and of skilled medical and surgical attendance—unless they should prefer to have the services of their own medical attendant or of some special surgeon, for whom, of course, they would have to pay themselves.

Lastly, coöperation between the various classes of hospitals is clearly needed. On this point I need hardly dwell, as Dr. Little and Mr. Spencer have fully pointed out the needs and advantages of it. I must, however, disassociate myself from Dr. Little's disparaging remarks on poor-law hospitals and their work. Speaking from my knowledge of the Scottish poor-law hospitals, they are not justified, and they cast an unmerited reflection on a body of medical men and on institutions that have done and are doing excellent work. It must not be lost sight of that from the earliest days our voluntary system has had close relations with the poor-law hospitals, as our word "infirmary" indicates. Dr. Little is not correct in saying that the voluntary hospitals have had an existence of 800 years; they are of much more modern origin and really date from the eighteenth century. The old hospitals like St. Bartholomew's and St. Thomas's, to which no doubt Dr. Little refers, were not originally voluntary hospitals; they were chartered and endowed hospitals, and made charges for treatment. Our voluntary hospitals as they exist to-day, owe their origin, no doubt, to the inefficiency of the medical services given at that time in the poor-law hospitals, but the latter have felt the good influence of the voluntary hospitals and are vastly improved—so much so is this the case that the voluntary hospitals are afraid that they may become serious rivals to them.

In conclusion, my object in writing has been to emphasise my view that the chief peril that threatens the voluntary system is political—it is a political party that desires to capture the hospitals and put them under State control. I consider that indirectly we are helping in this matter, for our present voluntary hospital régime has vulnerable points in its armour. These should be remedied without delay. The voluntary hospital system is by no means dead, but it contains elements of disintegration that need attention, for like everything else that is vital, unless properly tended and nourished, it will decay. Union and solidarity are urgently called for in connexion with it, for at present it resembles the bundle of sticks, each of which can be broken individually but not collectively. If we ourselves do not put our house in order, the Government will do so. The Government recognises that provision of proper institutional treatment in sickness must be provided for all classes of the community, because Ruskin's dictum that "the prosperity of a country depends on the number of people it can employ" is as true to-day as when spoken, and we know the number of working days and weeks that are lost through illness. There would, I think, be universal regret if our voluntary hospital system should disappear. As a nation, we are proud of it and of the splendid record of work that it has accomplished, besides, also, its being a working manifestation of that quiet, peaceful stream of brotherly love and sympathy that, year in year out,

flows quietly throughout the community, and that, when action requires it, shows itself in unbounded generosity and kindness.

I am, Sir, yours faithfully,

Glasgow, Feb. 17th, 1928. GEORGE THOS. BEATSON.

To the Editor of THE LANCET.

SIR,—Within the last few days a very authoritative manual upon hospitals, by Captain Stone, has been published. May I, in a final letter, give some of his figures, which I think corroborate certain statements made by me and adversely criticised by poor-law officials. These latter advocates have now retreated from their first position and rest their case upon conditions in London, in which they claim there are no empty beds at the poor-law institutions. Captain Stone says, p. 23: "There are in London 30 institutions with training schools for nurses attached and with available beds exceeding 19,000. The average number occupied is approximately 16,000, leaving about 16 per cent. of beds unoccupied." There would thus appear to be some 3000 empty beds at the poor-law institutions in the London area, a reserve which would more than cover the deficit at London voluntary hospitals, for in 1925 an estimate of waiting-lists was accepted by the King's Fund which showed that a provision of 2088 additional beds at voluntary hospitals in London would meet with a reasonable standard of adequacy the position of their waiting-lists. Since that date 1200 beds have, in fact, been added (in 1926) to voluntary hospitals in London. It is obvious, therefore, that the voluntary hospitals are now dealing with a much larger percentage of the demand than is sometimes represented to be the case.

I am, Sir, yours faithfully,

Feb. 20th, 1928. E. GRAHAM LITTLE.

To the Editor of THE LANCET.

SIR,—In your report of the special meeting of the Charity Organisation Society on Feb. 13th (THE LANCET, Feb. 18th, p. 342), to discuss the relationship of the voluntary hospitals and the public authorities, I am represented as having stated that 32 per cent. of the required revenue of the London voluntary hospitals was paid by public authorities. What I said was, that the total amount received from patients' payments, public authorities, &c., on account of services rendered was 32 per cent. Of this, 23 per cent. came from patients and their societies, and 8 per cent. from public authorities. These percentages are taken from the statistical report published by King Edward's Hospital Fund for London. It may be interesting to add that the percentage of patients' payments, including contributions from societies, has risen from about 9 per cent. in 1913 to 23 per cent. in 1926. The rapid growth of the Hospital Savings Association is evidenced by the fact that the Association paid to the hospitals in 1927 £127,196 for services rendered, as compared with £17,369 in 1924, the first year of its existence. Speaking on Nov. 28th, 1927, at the annual meeting of the Association, which was attended by a large number of group secretaries from all parts of London, Sir Alan Anderson said: "We are founded on a sure foundation, the affection which the voluntary hospitals have established in the hearts of the public who use them." It will be seen that a steadily increasing effort is now being made by those who use the hospitals to coöperate in providing for their maintenance.

I am, Sir, yours faithfully,

E. A. H. JAY,
Secretary for Propaganda, King Edward's Hospital Fund for London.

7, Walbrook, E.C., Feb. 21st, 1928.

PREVENTION OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—The very interesting communications on this subject which have been appearing recently in your columns have tempted me to submit some few cases which in their way are equally interesting. It has been the practice in this hospital since the beginnin of 1927 to immunise the nursing staff against dipl theria and to keep the positive reactors away fro the diphtheria wards until immunity was establishe During 1927 three nurses were warded with diphtheri

The first case was a nurse who was found to be Schic negative on Sept. 28th, 1927, and was therefore allowed t work in the diphtheria wards. On Dec. 9th she reporte with a sore-throat and was found to have a bilater follicular exudate.

The second case occurred in a nurse who was Schic positive on joining the staff and after one course of immunis tion had developed sufficient immunity to give a negativ reaction on April 12th, 1927. For interest sake she wa retested on Nov. 11th and again found negative. O Dec. 7th she reported with a sore-throat and the left tons was found to be completely and the right partially covere by typical diphtheritic membrane.

The last case was a nurse who was Schick-negative o Nov. 11th, 1927 (following active immunisation), an developed a patch of membrane on the left tonsil o Dec. 30th. In this case a specimen of blood was take well within 24 hours of the first complaint of sore-thro and the serum was found to contain 1/100th of a unit antitoxin per c.cm.

These three nurses developed diphtheria whil nursing cases of tracheotomy and were therefo exposed to a heavy infection. All three we admittedly mild cases and none developed paralysi Pure cultures of the Klebs-Löffler bacillus we obtained in every instance. That the toxin used f the Schick test was not at fault is evident from th fact that other nurses who were tested with the sam batches gave positive reactions. One case further worthy of mention—viz., that of a nurse who wa admitted to the London Fever Hospital with fauci diphtheria. There was membrane on both tonsi from which virulent diphtheria bacilli were isolate She had been Schick-tested at her own hospital an found to be negative.

However enthusiastic the claims for the Schic test and active immunisation against diphther may be, this type of case has still to be explaine And, provided that the activity of the toxin undoubted, the following explanations seem bot reasonable and possible. First, there are people wh although susceptible to diphtheria, may yet give negative Schick reaction owing to the insensitivene of their skins. In other words, the Schick reactio in some cases may not be a sufficiently sensitiv indicator of immunity or susceptibility. Secondl the blood antitoxin is not an unchangeable facto so that a small drop in its level will permit of a attack of diphtheria. And in this connexion it seem certain that there are a few people who never acqui a satisfactory immunity. Finally, there may b factors, not so important as blood antitoxin, whic may play some part in determining the immunit of the individual. These suggestions can only appl to those who possess only a borderline immunity.

That the blood antitoxin may not be the onl determining factor is suggested by the fact that a Schick-positive people, although constantly expose to massive doses of infection, do not contract dipl theria; and that a positive reaction with virule diphtheria bacilli in the throat (of which we hav had two cases in the last two years) is compatib with perfect health. Perhaps there is in some, wh have little or no blood antitoxin, an effective loc protection against the Klebs-Löffler bacillus.

This communication is submitted, not to detra from the importance of the Schick test or the result of active immunisation, but to suggest that th problem of diphtheria amongst the staff of a fev hospital is not yet completely over and that furth research is necessary before it becomes the complet success that is claimed for them. I should add tha I am indebted to Dr. C. R. Box for permission t publish these cases, under whose care they we whilst in hospital.

I am, Sir, yours faithfully,

R. MASSINGHAM,
Resident Medical Officer, London Fever Hospital.

Feb. 9th, 1928.

MASTOID OPERATIONS.

To the Editor of THE LANCET.

SIR,—The recent publication in THE LANCET Feb. 11th) of a paper by Mr. Heath on certain ıastoid operations prompts me to make a few ɜmarks.

It is generally agreed "that, in striving honestly urselves, we should heartily acknowledge the triving of our neighbour." Also that we should never ɔrget what is due to those who have gone before. In the light of history the present and the future ıay be interpreted and guessed at." This is no new pinion, for Celsus wrote: "Though we should not ɛfuse to give modern authors due credit for their iscoveries and happy imitations, it is none the less ıst to restore to the ancients what properly belongs ɔ them." To

> "Damn with faint praise . . . .
> And without sneering teach the rest to sneer,"

hardly cricket. But, after all, in some rcumstances—

> "To be dispraised, is no small praise."

Long years ago I met Schwartze and Stacke and was very familiar with the pioneer labours of von roltsch, Jacoby, Küster, Körner, Zaufal, and Eysall. ı the gradual evolution of truth, and at the end of ıch stage of the world's history, it would seem that great man appears, who is the messenger of a new nowledge, the herald of the dawn of a wider insight ıto life and truth. Such a man was Schwartze. ; is to the scientific insight and work of Schwartze ıat we are indebted for the discovery of the operation ɔr acute infection of the mastoid process. This was momentous scientific and surgical triumph. This ɔeration not only saves the life of the patient, but ıves intact the hearing.

When Mr. Heath disparages the operation, describes as altogether too primitive, and speaks of facial ılsy, dislocation of the incus, deafness, unsightly ɜars, painful dressings, inaccessibility of the mastoid ıtrum, prolonged suppuration, wounds that never ɛal, and fatal results, he must be thinking of and ɔnsidering some operation which Schwartze, if alive, ould not recognise as the one which bears his name. The object of the Schwartze operation for acute disease twofold, as is also the object of the Schwartze-aufal, or Schwartze-Stacke operation for persistent ıronic suppuration: (1) The removal of the disease, ıd (2) the conservation and improvement of the ɛaring. These have been the aims of all surgeons ! my acquaintance ever since these beautiful opera-ons have been devised and practised. They are ɔnservative operations. The surgical principles nderlying their performance cannot be varied without sk of failure.—I am, Sir, yours faithfully,

London, N.W., Feb. 20th, 1928. CHARLES BALLANCE.

CARBON DIOXIDE IN ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—With regard to your leading article last eek on the medical uses of carbon dioxide, may I ffer a few remarks on its employment in the lministration of anæsthetics? My clinical experience ıs not led me to consider it to be of sufficient ıportance to be included in the anæsthetist's equip-ɛnt; it may even prove a cause of anxiety if the ɔparatus is not in perfect order and an overdose ɛ inadvertently given.

It has been stated that the presence of CO_2 in small ıantities is likely to obviate holding the breath and ıus bring about a quicker induction. In adults ɔlding the breath and struggling by the patient ıring induction I find to be of very rare occurrence ɛdeed if the induction is commenced by careful ıd tactful measures. There is no object in making ıe induction so short that the patient is discomforted. he mask in the open method can be held 3 or 4 inches om the face with very little anæsthetic on it, the ıount gradually increased, and the distance from the face gradually decreased, and by the time it is actually on the face most patients are sufficiently asleep without struggling for the anæsthetic to be more quickly pushed and the vomiting centre controlled. Neither have I experienced simple arrested respiration which has not very soon been restored either by waiting a minute or two or by cutting off oxygen if it was in use at the time. Of course, one would not wait a moment if the pulse stopped before taking measures to restore the dormant heart.

Lastly, the advantage claimed for increased respiratory action and amplitude from inhaling CO_2 after an operation, in order to wash the anæsthetic more quickly out of the system, may be open to objection on the grounds that the patient is called upon to use his respiratory muscles in excess while in a state of fatigue instead of waiting till he has gradually gained strength.

Dr. R. M. Waters's observations on the danger of CO_2 in cases of acidosis are very important, more so of course in respect to children than adults.

I am, Sir, yours faithfully,

St. James Court, S.W., Feb. 20th. JOSEPH BIRT.

GASTRO-DUODENAL ULCERATION.

To the Editor of THE LANCET.

SIR,—For the past two years I have been practising this method of treatment on lines very similar to those described by Prof. H. MacLean and his colleagues. I can substantiate the full claims made by them that this is the only real effective method of dealing with the ulcer. In one series of 25 cases (the early ones) 24 became quite well and have kept well, the twenty-fifth was one of marked pyloric stenosis and was put on the alkali as a temporary measure till the operation advised was performed.

The use by the writers of the word "cure" seems have raised a difficulty, but the 24 patients of whom I write are quite definite about it, and as no evidence of ulcer, radiological or otherwise, is found in their case, may one not reasonably assert they are "cured"? The method used was a modification of Sippy's. He was quite clear (*Jour. A.M.A.*, 1915) on the question of cure and even included all cases of pyloric stenosis except those of extreme narrowing due to definite cicatricial contraction following a healed ulcer. That the method does control the hyperacidity can be proved by the Einhorn tube, and it is well to acknowledge, as claimed by MacLean, that it is the *continuous* secretion of HCl which requires controlling before healing takes place. In my cases I never met with an alkalosis.

It may be suggested that the quoted cases are of too recent a date to warrant the assertion of cure, but they may be of interest following the much longer experience of those others. I have the temerity to publish them since I have seen nothing from any other source in this country of this particular method.

I am, Sir, yours faithfully,

A. J. D. CAMERON, M.B., Ch.B.

Northampton, Feb. 15th, 1928.

THE DISPOSAL OF THE DEAD.

To the Editor of THE LANCET.

SIR,—In a leading article under this heading, appearing in your issue of Feb. 11th, reference is made to the fact that 166 out of some 200 municipalities had given categorical responses to request for information about cemetery undertakings, a response which you rightly regard as "an unusual event." May I, in fairness to the various authorities and in acknowledgment of the courtesy shown in responding to the questionaire, be allowed to point out that as a matter of fact every authority applied to responded. One hundred and sixty-six sent as complete and detailed information as they were able (and in the bulk of cases replied to each question on the form). Thirty-one other authorities also replied, but as they did

not control any cemeteries were naturally unable to supply information. We may fairly assume that the information would have been supplied had they been able to give it. The actual position is: 198 authorities were applied to, 197 replied as fully as they were able, and one only declined information. Each of the authorities has been supplied with a copy of the book and it is hoped that this publication will convey useful information in regard to a matter upon which the public might properly be informed. The figures are only carried as far as March, 1926, but it is unlikely that statistics brought down to a later period, or even carried to 1929, and possibly thereafter triennially, would show any marked change.

Cremation is of slow growth, but is making steady progress. It hardly seems necessary, however, that burial should be subsidised by ratepayers when, by the adoption of cremation, such a course would become unnecessary.—I am, Sir, yours faithfully,

Manchester, Feb. 13th, 1928. ARTHUR E. PIGGOTT.

To the Editor of THE LANCET.

SIR,—The Infectious Diseases (Prevention) Act, 1890, Section X., provides the powers that Prof. E. L. Collis suggests the lack of in his letter in your last issue. Acting under this section, I have had no difficulty in obtaining the burial of bodies retained or intended to be retained for more than 48 hours in the house where this was undesirable, not necessarily on account of infectious disease. The section specifically states that the power applies to *any* body.

I am, Sir, yours faithfully,

H. KERR.

Feb. 20th, 1928. M.O.H., Newcastle-upon-Tyne.

AGGLUTINATION OF *MICROCOCCUS MELITENSIS*.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 17th, 1927 (p. 1290) Dr E. Wordley asks if the agglutination of a patient's serum against *M. melitensis* in a dilution of 1/400 is sufficient "in cases of this type to justify a diagnosis of undulant fever?" Old subcultures of *melitensis* will often agglutinate to this dilution with sera taken from patients who have had pyrexia for a week or more, for *melitensis* is particularly susceptible to agglutination by the serum of patients who are suffering from chronic streptococcal infections. I recall one case of endocarditis due to *Strept. viridans* in which the serum agglutinated *melitensis* up to a dilution of 1/1000.

I am, Sir, yours faithfully,

LUCIUS NICHOLLS.

Bacteriological Institute, Colombo, Ceylon, Jan. 14th, 1928.

Public Health Services.

ULTRA-VIOLET TREATMENT AT PUBLIC BATHS.

THE Baths Committee in Manchester recently put forward a proposal to establish artificial sunlight centres at the public baths in the city, and the proposal came before Dr. R. Veitch Clark in his capacity of medical officer of health. Dr. Clark's reply to the proposal was substantially this:—

"There is only one correct way in which to regard the use of ultra-violet rays—i.e., to view them as a means of medical treatment. Any scheme which does not provide for adequate medical supervision, both of the clinic and of the people who receive the treatment, is not a mode of action which can properly be adopted by a public health authority. Ultra-violet rays exert an extremely powerful influence on the body; thus, the constitution of the blood is very profoundly changed, and a high degree of stimulation is possible in many individuals subjected to these rays. The dosage, therefore, must be carefully graduated and controlled to suit each individual if the possibility of harm is to be avoided. This control can only be effected properly by medical supervision."

The Ministry of Health have refused their approv of any such installation unless the equipment a the patients are under the personal control a supervision of a medical man or woman who h been specially trained in the use of ultra-violet r apparatus. Dr. Clark therefore felt himself unable support the proposal of the Baths Committee.

INFECTIOUS DISEASE IN ENGLAND AN WALES DURING THE WEEK ENDED FEB. 11TH, 1928.

Notifications.—The following cases of infectio disease were notified during the week:—Small-po 369 (last week, 386); scarlet fever, 1832; diphtheri 1562; enteric fever, 48; pneumonia, 1578; puerper fever, 53; puerperal pyrexia, 107; cerebro-spin fever, 11; acute poliomyelitis, 11; acute poli encephalitis, 1; encephalitis lethargica, 3 dysentery, 17; ophthalmia neonatorum, 125. The was no case of cholera, plague, or typhus fever notifi during the week.

The cases of small-pox were notified from the followi 25 counties: London, 5 (Holborn 1, St. Pancras 2, Sout wark 2); Berks, 2 (Reading, Bradfield R.D., 1 each Buckingham, 1 (Amersham R.D.); Chester, 2 (Maccl field); Derby, 12; Durham, 87; Gloucester, 4 (Bristol Gloucester 1, Kingswood 2); Hertford, 3 (St. Albans Watford 2); Lancaster, 29; Lincoln, Parts of Kesteven Parts of Lindsey 2; Northampton, 2 (Daventry Wellingborough 1); Northumberland, 14; Nottingham, 2 Somerset, 1 (Wells); Southampton, 1 (Kingsclere R.D. Stafford, 5 (Newcastle-under-Lyme); Suffolk East, (Ipswich); Surrey, 1 (Guildford); Warwick, 14; Yorkshi North Riding, 12; West Riding, 37; Brecknock, 1 Glamorgan, 32; Monmouth, 67.

The number of patients at the Infectious Hospitals of t Metropolitan Asylums Board on Feb. 14th–15th was follows:—Small-pox, 19 (including 3 cases and 1 cont under observation); scarlet fever, 1749; diphtheria, 256 enteric fever, 23; measles, 1409; whooping-cough, 17 puerperal fever, 19 (plus 14 babies); encephali lethargica, 76; poliomyelitis, 1; "other diseases," At St. Margaret's Hospital there were 11 cases of marasm and 9 babies (plus 5 mothers) with ophthalmia neonatoru

Deaths.—In the aggregate of great towns, includi London, there were 2 deaths from small-pox, 1 (0) fro enteric fever, 78 (45) from measles, 5 (2) from scarl fever, 39 (4) from whooping-cough, 40 (7) fro diphtheria, 41 (5) from diarrhœa and enteritis und two years, and 111 (24) from influenza. The figur in parentheses are those for London itself. Of t 33 fatal cases of measles outside London, 8 we reported from Manchester, 6 from Bristol, 5 fro Sheffield, and 3 from Warrington, while the figu from Glasgow and Dublin for the same week we 26 and 13 respectively. The number of stillbirt registered during the week was 295 in the great tow including 46 in London.

The two deaths from small-pox were reported fr London (Southwark) and Newcastle-on-Tyne. The form was that of a man, aged 45, the cause of whose death w entered in the certificate as (1) subacute nephritis (2) chro bronchitis, (3) discrete small-pox. The latter was that a man, aged 53, of no fixed abode, who was in the small-p hospital with "very mild small-pox" from Dec. 2nd–17 and who died in Wingrove Hospital on Feb. 2nd, his certific being filled in thus: (1) pericarditis, (2) debility followi small-pox, (3) tuberculosis of lungs (no post-morter This man's vaccinal condition was given as: success vaccination (infancy only), two marks, total area one-h square inch.

MARGARET-STREET HOSPITAL FOR CONSUMPTION. At the annual meeting of the governors of this institut it was stated that the hospital, which is situated just Cavendish-square, London, was used by the Ministry Pensions as a clinical centre to which are referred pensio officers and nurses whose disability is classified as pulmon tuberculosis. More than 360 such cases have been de with, of whom over 100 are receiving treatment. Increas use is being made of the dental evening clinic established 1925. The need was pointed out for a sanatorium for wom and children; at present men only from the out-pati department can be treated at Fairlight Sanatorium.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

New Pensions Hospital.

On Monday, Feb. 20th, the House of Commons went to Committee of Supply on a supplementary estimate ken vote of £10 for expenditure in respect of sundry iblic buildings in Great Britain not provided for in other tes.

Sir V. Henderson, Under Secretary to the Home Office peaking on behalf of the First Commissioner of Works), plained that this token vote was really in connexion with e provision of hospital accommodation in a new Ministry Pensions hospital at Dunston Hill, Newcastle-on-Tyne. ie new hospital would deal, he said, with general medical d surgical cases. The present hospital had been in use ice 1920, but the accommodation there was now more than s required. The present hospital accommodated about 0 patients, whereas the actual requirements at present l not exceed 120. It was held on a three years' lease, ich expired on Sept. 30th of this year. The nurses ployed at the hospital were quartered in a building ne distance away, at a rental of £315, and the lease of ir quarters would expire about July 30th of this year. had now been decided to rehouse the patients and the rses in one building, and arrangements have been made take a lease for 14 years of the old manor house and unds known as Dunston Hill, five miles from Newcastle. e lease was determinable, if necessary, at the end of en years, and the rental was £330 a year. The cost of alterations and works services would be £22,565, while niture and fittings would cost £625, and removal expenses 25. It would house 120 patients and would also accommoe the nursing staff. The rehousing, so far as the nurses re concerned, would be complete by July of this year. was estimated that there would be a saving on the new eme of not less than £6800 per year. It was possible to l with the matter by a token vote, owing to the necessary ney having been obtained from savings on certain other vices.

Lieut.-Commander Kenworthy said that the scheme was ery good one indeed. He congratulated the Ministry of sions on deciding to remove this hospital out into the ntry and he wished that had been done in 1920 when the ginal hospital was acquired. He had never been able to erstand why so many hospitals under the Ministry of sions had been placed in noisy towns and on main ffic routes. That was a mad thing to do. They ought have been taken out into the country and accommodated he country houses which were now a drug on the market. his experiment proved successful he hoped that it would tried elsewhere. The lease of the new hospital was, his opinion, too short; it ought to have been for years. After it ceased to be necessary for the use of Service men it could be taken over by the Ministry of alth and used for the treatment of tuberculosis. There a tremendous shortage of such hospitals on the north-coast. He believed that the real solution of the difficulty ld be to have Government hospitals in the future.

Sir V. Henderson said that it would be out of order him to deal with the question of the future of the hospitals with the question of their control by the Ministry of alth. The Office of Works considered that 14 years' lease quite sufficient. The new hospital would be well away n the road and the house stood in its own grounds.

The vote was agreed to.

Health Insurance.

On a supplementary estimate of £340,000 for the salaries expenses of the Ministry of Health, including grants id, in respect of benefits and expenses of administration er the National Health Insurance Acts.

The vote included a sum of £210,000 in respect of sickness blement, maternity, &c., benefits additional to the inal estimate.

Sir Kingsley Wood (Parliamentary Secretary to the istry of Health), in presenting the estimate, explained the £210,000 was necessitated by the continuing high enditure on benefits by the approved societies. There been an increase in the number of attendances of insured ons for medical treatment, and claims for benefit had n made very freely. This state of affairs, no doubt, was ntuated in a time of considerable unemployment. as a very disturbing position. The Ministry of Health taken every suitable opportunity of reminding societies he need of strengthening the supervision of insurance ns by such means as improved sickness visitation and use of the Regional Medical Services. The matter had n constantly discussed with the medical profession at ry conferences, and the British Medical Association had the matter under close consideration as a result of a meeting with them on Jan. 19th last. New regulations were brought into operation from Oct. 1st, 1927, whereby a fortnight's delay was imposed on the transfer from one doctor to another, except where both doctors consented. That might have some material effect on these claims.

Criticism of Panel Practitioners.

Mr. Rhys Davies said they were informed that 150,000 persons had come into the Health Insurance scheme as voluntary contributors under the Widows and Orphans Contributory Pensions Act, about 10 per cent. above the estimate of the Actuary, and surely the Minister of Health must be aware that these lives were not so good as the lives of those who were compulsorily insured. He wished to ask whether that increase in the actuarial estimate did not contribute partly to the amount required under this supplementary estimate. He also criticised the medical profession because what they were failing to do accounted more than anything else for this increased expenditure. Three of the approved societies in Durham had made a complaint about loose certification. No approved society, so far as he was aware, declined any genuine claim for disablement or sickness benefit at any time, but when they were doubtful and suspicious that a doctor was giving medical certificates merely to increase the number of insured persons on his panel, the societies were entitled to say that that doctor should be stopped. He knew that members of the medical profession were very much irritated when any criticism was levelled against them, and he felt sure that they would hear, in the course of that discussion, that the panel doctor could not increase the number of insured persons on his panel merely by granting certificates loosely. But if it was known that a doctor would grant certificates without adequate examination, while another doctor insisted upon adequate examination, a panel patient would sometimes go to the doctor who was most loose in his certification. The Insurance Committee for the County of Durham had passed a resolution asking the Minister of Health, to whom they sent the whole data, to conduct an inquiry into this subject of loose certification. What was the Minister of Health doing about it? As a matter of fact the Minister of Health was afraid of the medical profession. When it was a question of dealing with a board of guardians they had heroics, but when the British Medical Association was "on the job" then the Minister quaked at once. Was it true that this increased expenditure was in part due to the fact that the stamina of the people had deteriorated because of poverty and destitution? Was it the experience of the approved societies that the increased sickness was greater in the distressed areas? That could easily be found out. He was very sorry to be so critical of the medical profession, but in Lancashire there had been criticism in connexion with the method of prescribing. Some persons argued that they were not getting sufficient medicine; for his part he wished they took less of some of the medicines there were taking. The fact that the panel practitioners were not carrying out their duties under the National Health Insurance Act accounted in great measure for this increased expenditure. He would give some figures to prove that where a panel practitioner had a great number of persons on his panel he was not so careful in prescribing for the chemist. In cases where a doctor had 2500 persons on his panel the average frequency per insured person in connexion with prescription was 0·354; when he had less than 1000 persons on his panel the average frequency was 0·237. There had been several allegations in Salford that doctors had been "touting," and he understood that there had been an inquiry into the allegations. He would like to know what was the result of that inquiry. He wished to add that the medical profession, as a whole, could not be charged with doing what he had suggested. They were not guilty of it, but only just a few, who ought certainly to be brought to book by the Ministry of Health and made to do their duty to the State and to the approved societies. It was a fact that some approved societies had had to realise their investments to meet the claims for benefit. That was the most serious aspect of the work of the societies, and this was the first time that they had been in this position. Were it not for the interest on their investments, the approved societies would now be heading straight for bankruptcy. In 1926 the total sum brought into the approved societies' funds in contributions amounted to £24,000,000; the Treasury grant was £7,000,000; and the interest on investments £6,000,000—a total of £37,000,000. Payments in respect of benefit amounted to £30,000,000, and the cost of administration to £5,000,000. That made a total of £35,000,000, and left a balance of only £2,000,000. The interest on the investments of these societies ought to be safeguarded by the Minister of Health, but he had been brow-beaten by the Chancellor of the Exchequer. Did the extension of the average age of the insured persons in the last decade account for the increase in the average rate of sickness? He wished to ask some questions with regard

to the work of the regional medical officers. Was it a fact that some panel doctors, who were in practice themselves, were also acting as regional medical officers? He took it for granted, of course, that a panel doctor did not become a judge of his own case. How many regional medical officers were there, and were they sufficient? How many regional dental officers were there? The work of these officers had been very good; were there sufficient to carry out their task? The Minister of Health might consider the appointment of some one to act in the same capacity in relation to optical treatment and appliances as he had done in regard to dentistry. Such an appointment was very necessary, because he was sorry to say of all these professions that once they saw an accumulated sum of money in the funds of approved societies, they began to organise definitely in order to get their share. Primarily that money belonged to the insured population, and the Minister of Health ought to appoint some person to check the opticians, just as the dentists were now being checked.

Certification Difficulties.

Mr. MELLER said he found himself very largely in agreement with Mr. Davies. He had brought before the Committee some matters which deserved the very close attention of the Minister of Health. He was very glad to find that in Mr. Davies's reference to the sickness experience of societies he did not allege that there was malingering amongst insured persons. He believed that malingering in this country was very rare, and he believed also that the malingerer was made and not born. If any malingering had occurred in connexion with the sickness experience of societies in this country, it had been due, very largely, to the lax methods which had been adopted by the medical practitioners, and he wanted to join with Mr. Davies in saying that, although the allegations which he had made with regard to doctors extended only to a few, and that a very large proportion of doctors endeavoured to carry on their work quite fairly and properly in the best interests of their patients, there were, unfortunately, many instances in which doctors had not paid that regard to the patient which they ought to have paid. They had been free enough to give medicine where medicine might not have been required, but had been slow in giving what he believed was very much better than many bottles of medicine—that was to say, moral courage to the person not to remain upon the funds—to give them a few healthy admonitions and send them about their business. In his view, and there were many instances to prove it, the medical profession had themselves said that their difficulty had arisen from the fact that they found it extremely hard to maintain the patients on their panel with the competition of other doctors in the neighbourhood. Many a man started to-day not by buying his practice but by putting up his plate and hoping that the number of insured persons would be fairly distributed in the district, and that he would get his share. It was not perhaps unnatural for him when he was told that the patient was suffering from some complaint which he could not diagnose and which he could not disprove, to give him his certificate quite readily. There had been instances, and a good many unfortunately, of medical men themselves saying that patients had come to them and said, "If you do not give the certificate I can get one down the street." The medical man in such a case had found himself in the dilemma of either retaining the patient or seeing him go to another doctor, and in this way he might lose not only insured patients but patients who might not be insured persons. It was a difficult position, and unfortunately it seemed to be spreading. The best men in the medical profession were standing out against it and wanted to stop it, and he believed that the Ministry of Health was anxious to assist the strong doctor in resisting these unfair claims upon him and the unfair competition of certain men in the profession. One point which he (Mr. Meller) regretted very much indeed was the comparative ease of transfer from one panel doctor to another which had been allowed. Under the old system when a period of six months or even a year was required there was no hardship to the insured person, but it gave the doctor the opportunity of acting as firmly as he ought to act. The present practice which gave the opportunity of transferring at any moment, with the consent of the late doctor and the proposed new doctor, or the other common practice that with a fortnight's notice a man or woman might transfer from one doctor to another simply because they might have been upset by something the doctor had said, was improper and ought to be stopped. Indeed, he believed that the medical profession themselves were in favour of a longer period between the transfer from one doctor to another.

Mr. Davies had made some reference to the regional medical officers. That body was set up some time ago because it was discovered that a very large number of claims were being made upon societies without any real grounds to justify them. Certificates of comparatively minor ailments continuing for some time, such as debility, were given, and there was no satisfactory means of checking the doctor. Thereupon the Ministry set up regional medical officers, and what had been the result? If hon. Members would turn to the report of the Ministry of Health for 19[illegible] they would find there some figures with regard to the number of cases submitted for examination in that year, and they would find that some 420 cases were sent by societies to be examined by the regional medical officers because the societies had some doubt as to the genuine incapacity of the insured persons concerned. There were 450,000 cases referred, and of that number about 60 per cent. either declared off before the examination or were found to be capable of work, while only about 40 per cent. of the people who had been referred by the societies were found to be incapable of work. It did seem that there was something wrong in a method of certification which allowed certificates to be issued in respect of 60 per cent. when they ought not to have been issued, and that only 40 per cent. of the cases were incapable of work. If it meant that they needed further examination, further overseeing of the medical men, he hoped that the request of Mr. Davies would be acceded to by the Ministry of Health. Some reference had been made to the fact that certain of these medical officers were themselves in practice and were conducting their examinations as part-time officers. Perhaps in fairness to them it ought to be stated that they did not examine within their own area, but he agreed that it would be very much better to have these medical referees entirely free from any suspicion, and devoted only to the work of examining panel patients and not having to bring up against them their own private practice.

Health Conditions in Monmouthshire.

Mr. BARKER said he rose to oppose this grant to the Ministry of Health. The condition of health in his constituency, and in Monmouthshire generally, was deplorable in the extreme. There was more disease there to-day than had been known for 20 years. The medical officer of health of the Brynmawr Urban District Council in a report recently published said that up to the present 140 cases of small-pox had been attended to. One cause of the spread of small-pox was that the people were not taking sufficient nourishment, particularly the children, among whom the great[illegible] number of cases had occurred. The Ministry of Health was not fit to be entrusted with the spending of any money. The medical officer of health of Nantyglo in a report published last December said the water was dangerously polluted, small-pox was spreading, the death-rate was twice what it was in the previous month, and 78 per cent. of the male population were unemployed. The same medical officer said that the people were under fed. Dr. Rocyn Jones, medical officer for the county of Monmouth, has stated this month that small-pox continued its devastating work among the people of Monmouthshire. They had had 2200 cases of small-pox in the county since the epidemic commenced in February, 1927, and 522 cases, or 24·9 per cent., were said to be vaccinated. The medical officer further said that hospital accommodation was being taxed to its utmost. The disease was continuing to spread, many areas being involved. He also made the statement that the County Council had spent over £22,000 on this disease and that in a very short time they would have to spend £100,000. The health of the working classes, Mr. Barker contended, was being endangered by the apathy of the Ministry of Health.

Altered Relations between Practitioner and Patient.

Dr. VERNON DAVIES said that there seemed to be in that debate rather a concerted attack upon members of the medical profession, which might perhaps, to a certain extent, have been justified, or might not. One of the fundamental difficulties of the National Health Insurance Act was the question of certification and the free choice of doctor. The whole system of medical behaviour between doctor and patient had been altered. In the old days the doctor, as a rule, was the friend, helpmeet, and medical adviser of his patient, and his patients trusted and obeyed him. But the Insurance Act created a new state of affairs and the medical man, instead of being the master, became the servant of the insured population. They could take him on when they liked and dismiss him when they liked. Panel practitioners were human beings, and in the majority of cases had their living to earn. As a rule, panel practitioners were as good, or as bad, as ordinary individuals, and they could be divided into three sections. There was the man who was conscientious, honest, and determined to do his best, and, at the other end of the scale, they had the man who was perhaps not so particular. He would not say that he was dishonest, but perhaps he was a little lax and careless. Between these two extremes was the man who wanted to do what was right and was not able to do so. What was the reason? A patient came to the doctor to get a certificate. The doctor, if he was honest, as all doctors would like to be, gave a certificate if he thought that the patient was entitled

to it. The difficulty did not occur at the onset of the illness, but towards the end, when the patient should go back to work. The doctor might think that the patient was fit for work, but the patient might think that he was not, and desire to draw benefit a little longer. The honest, conscientious doctor would cross the man off; but the doctor who was not quite so particular said to himself: "I might as well please my patient." The other man perhaps said: "It is my object to have as many patients as I can, and if I can please my patients it does not matter about the National Health certificate." So long as they gave the patient the free choice of doctor they would be up against that difficulty. The difficulty did not always end there, because the man might have a family of five or six children who were private patients. The man might leave the doctor and not allow any of his family to go to him. Moreover, the same man might say to his friends that Dr. So-and-So was too particular and signed one off far too quickly. The doctors undoubtedly were to blame in certain cases, and he had no desire to stick up unnecessarily for the medical profession. On the other hand, they must remember that they were putting very great temptations in the doctor's way. The doctor was in a very difficult position. He might be deceived by patients in certain cases if the patients wished to deceive him.

The Approved Societies.

On the other hand, the doctor was up against the approved societies, who were a perfect nuisance, and an extremely foolish body of individuals. An essential point in the administration of the National Health Insurance Act was that the medical man, the approved societies, and the chemists should work together, because their aims were the same—namely, to keep the insured persons healthy and to administer the funds to the best advantage. The approved societies did not like to pay benefit if they could help it, and when benefit was paid they were anxious that the patient should get off benefit as soon as possible. He would not say that they went spying round, but they sent their visitors, and if a poor woman happened to be lifting a kettle off the fire, or if she had a duster in her hand, or if a man happened to be out one minute after 6 o'clock, there was trouble. Instead of working with the medical men, the societies were too apt to send cases to the medical referee. He had found over and over again when he was in practice that the majority of cases thus sent to the medical referee were the absolutely genuine cases and the particularly doubtful cases had never been spotted at all. If the approved societies had asked his honest opinion they would have got it, and in that event they would have been able to send to the referee the proper cases. They had worked against the medical men because in the old days of the club they had the medical men under their thumb, and had never forgiven the Ministry of Health and the Government for deciding that the doctors should not be put under the approved societies. It was absolutely necessary that they should make the right of free transfer very much more difficult than it was. No patient should be allowed to transfer without giving a specific reason. Mr. Rhys Davies had said that there had been a lot of over-prescribing. That was true, but again the doctor was in a very difficult position. If a patient said he was ill and wanted a bottle of medicine and the medical man refused to give him one, and told him to go home and do something that would do him good, the patient thought that he was not being properly treated and that the doctor was no good. Such a doctor might find that a complaint had been made against him to the Medical Committee or the Insurance Committee, and that might cause him some trouble. Therefore, when a doctor found that he had a discontented patient, he gave a bottle. When he went into practice in Lancashire it took him years to persuade certain patients that they were better off without a bottle of medicine than with it. A doctor in the old days gave a patient a bottle purely for financial reasons. Fortunately, at the present day people were getting better educated and recognised that medicine was not always necessary. At the same time there was in the industrial population the greatest belief in the efficacy of a bottle of medicine and they could not afford altogether to neglect the psychological effect. He thought that a panel of 2500 was far too many for any medical man. As a rule, doctors had private patients as well as panel patients. The danger was that a doctor might miss something and then there was a scandal. But what was the doctor to do? If a doctor had 2000 patients on his panel it meant about £800 a year. That sum did not go far, as the expenses of a doctor were appalling. The result was that a doctor must have a big panel to make it a paying proposition, and if they gave him a big panel he could not do the work properly. At some time or other he was bound to neglect it and there would be complaints. Mr. Rhys Davies had also raised the question of "touting" for patients. That was another curse of the National Health Insurance Act. There could be no doubt that since that Act came into force the standard of medical men had deteriorated and there was not the same class of men coming into medicine to-day as there was 15 or 20 years ago. His impression was that medicine, instead of being a profession, was now becoming a trade. Therefore, they would get these cases of "touting" where a young man anxious to make a practice would do something or other to get others in. Referring to the remarks of Mr. Barker, Dr. Davies said that malnutrition was not a cause of small-pox. If people would get vaccinated they would not get small-pox. Proof of that could very easily be found. The only reason there could be for a huge epidemic was that 50 per cent. of the children were unvaccinated. The sooner members of the Labour Party understood that fact the better.

Mr. WHITELEY said that there had been loose certification in Durham. There was a great desire in that county that there should be an inquiry. Something ought to be done, at least to show these medical men that they could not go on doing as they liked without any regard either for the patients they attended or the approved societies of which the patients were members.

Reply to the Debate.

Sir KINGSLEY WOOD, replying to the debate, said that the increase in the level of sickness had been pretty general, and was not characteristic of any particular industry. He wished to correct the view that had been put forward as to the number of insured people who were permitted to go on the panel of a particular doctor. The figure of 2500 had been mentioned, but that was not correct. The maximum number of insured persons permitted to a single panel practitioner was 2000. The average number of insured persons on doctors' panels up and down the country was not anywhere near 2500, but about 1000. It was a matter of considerable controversy and anxiety why the very large sum of money provided under the Insurance Act for sickness benefit should have been exceeded. It was true that the influenza epidemic did not wholly explain the persistence of the high expenditure, and it might be that insured persons were looking more carefully to their rights under the Insurance Act, and that their claims for benefit were being made much more freely. The statements which he had made in that House 12 months ago had been very amply confirmed in all parts of the House that night. He found that the number of cases referred to the Regional Medical Officers for a second opinion rose from 201,291 in 1921 to 377,180 in 1926, which was an abnormal year owing to the industrial troubles in that period; and was actually 313,011 in 1927. Comparing the figures of 1927 with those of 1925, he found that the number of persons referred to the Regional Medical Officers had increased by 55 per cent. These were astonishing results, because the proportion of persons examined who were found to be capable of work increased from 24 per cent. to 28·8 per cent. Another astonishing figure was that 44 per cent. of the people who were referred to the Regional Medical Officers failed to attend the examination, or "declared off" before the date of their examination, and the proportion of persons referred for examination who came off the fund, either by failing to attend or as the result of the medical examination, increased from 57·7 per cent. to 59·8 per cent He was not going to endeavour to say who was responsible, whether it was the people who presented themselves for examination, or who failed to attend after notice had been given to them that their case was going before the Regional Medical Officer, or whether it was due to faulty certification by the medical profession. But these facts showed that the approved societies and the medical profession of the country had seriously to take this matter into account, because this excessive sickness was bearing on the approved societies, and the people who had to stand the racket in the end were the insured persons. It was only right that, so far as they were concerned, the very greatest care and precaution should be taken in regard to the administration of their affairs. With regard to the financial position of the societies, a very interesting thing, which would be of great benefit to the health of the community and the next generation, was that additional benefits costing in the aggregate upwards of £8,000,000 a year were at present being distributed out of surpluses made available as a result of the last valuation of the approved societies. This large amount of additional expenditure was being made largely out of current funds, without drawing on existing accumulations of funds. It was ridiculous to suggest that the societies could distribute these large surplus funds without making some realisation of the assets available for that purpose. The investigations into sickness should be of various kinds. In the first place, the Ministry had impressed on the approved societies their responsibility in the matter. In the second place, the Ministry had had a conference with the British Medical Association, who were engaged in an inquiry into this particular matter. Thirdly, the Ministry had advised the increased use of medical referees. The department was anxious to obtain, as far as possible, self-government by the approved societies

and to secure that National Insurance, so far as possible, should be conducted by the societies themselves.

Mr. RHYS DAVIES: Is the hon. gentleman aware that the approved societies have little control over the medical profession?

Sir KINGSLEY WOOD said that Mr. Davies knew the difficulties and delicate matters that obtained in a profession of this kind, but he thought that a very fair balance had been struck between the representatives of the approved societies on the one hand and of a great profession on the other. "You cannot," Sir Kingsley Wood went on, "make the medical profession the servant of the approved societies, but administering as they do an Act of this kind, they must be prepared to obey certain rules and conditions which I think are fair and sufficient. This discussion will serve a useful purpose in bringing these facts before the country. The House has seen the serious state of affairs as far as sickness is concerned. The speech of Mr. Davies was a reasonable one, and did not disguise the seriousness of the position, or the fact that there is a large number of people obtaining benefits which they ought not to obtain. Everyone who values the work of the approved societies must realise that these things must stop."

Effect of Insurance on Health.

Dr. WATTS said he held no brief for the panel doctor. Indeed his personal opinion was that any man in the medical profession who accepted service under the National Insurance Act deserved what he got. The Act had had an ill-effect on the health of the country generally, and he knew personally that there were many people in the graveyards of this country to-day who would not be there but for the National Health Insurance Act. That Act was the greatest fraud ever perpetrated upon the country, and his suggestion was that it should be repealed. In regard to the question of certification, the panel doctor naturally took the line of least resistance and accepted the statements of his patient, as it would be manifestly impossible to make a thorough and detailed examination in each case. Therefore it was unreasonable for hon. Members to blame panel doctors, foolish and misguided individuals though they might be, to take service under the National Health Insurance Act. Unquestionably the approved societies had of late years been entirely wrong in their administration of the Act.

The vote was agreed to by 189 votes to 96.

HOUSE OF LORDS.

TUESDAY, FEB. 14TH.

Children and Traffic Accidents.

The BISHOP OF SOUTHWARK called attention to the statement of the Education Officer of the London County Council that in 1926, in the metropolitan police area, 233 children were killed and 9528 were injured through traffic accidents.

Viscount PEEL (First Commissioner of Works) said that the Advisory Committee on Street Accidents appointed by the Minister of Transport had presented a report about a year ago. The Committee was set up because of the anxiety of the Ministry of Transport to see what could be done to cope with dangers of the streets. Even before the Committee reported the Minister had summoned a conference of local authorities, different Government departments, interested persons connected with motoring, &c., to discuss these problems. A circular was sent round to education authorities urging them to do what they could to educate children in regard to the dangers they incurred in crossing the streets and matters of that sort. They also called attention to the necessity for playgrounds being provided so that the children could be kept off the streets. It was, however, very difficult to provide sufficient playground accommodation in overcrowded districts, of which Bermondsey was an example. The Bishop of Southwark had suggested that a committee should be set up to inquire further into this question. He (Lord Peel) understood that the Advisory Committee were now considering these problems and would report very soon to the Ministry of Transport. In view of this, he thought it was hardly necessary at this moment to set up another committee. The Minister of Transport, however, had authorised him to say that he was prepared to give a special direction to the Committee to consider particularly the problem of accidents to children and consult with representatives of the police and local authorities in order that they might decide upon certain definite rules to reduce the number of accidents to children.

HOUSE OF COMMONS.

TUESDAY, FEB. 14TH.

Scottish Creameries and Preservative Restrictions.

Brigadier-General CHARTERIS asked the Secretary of State for Scotland whether the representations which had been made by the creameries of Scotland regarding the effects both on their business and on the supply of cream to larg towns, of the recent order restricting the use of preservativ in cream had been investigated; if so, with what result and whether he was prepared to receive a deputation o interests affected in the near future.—Sir J. GILMOUR replied Only a few creameries in Scotland have made representation regarding the effect of the prohibition of boric acid in cream Since Jan. 1st, the date when the regulations came int operation in regard to cream, the Scottish Board of Healt have made inquiries in many districts and cities affected The reports obtained show that in the south and south-wes of Scotland there has been some trouble with cream goin sour, but to a considerable extent this is to be attribute to the fact that no sufficient use was made of the two an a half years given as a period of grace by the preservative regulations, so as to secure improvement in the methods an conditions of production and distribution. Active steps ar now being taken by many creameries, including the promotio of clean milk competitions among producers to improv the hygienic and keeping qualities of the milk from whic cream is produced. There is substantial evidence that crear properly produced from clean milk, and properly handle will keep sweet for several days. The Scottish Board o Health accordingly see no reason to rescind the regulation as far as they apply to cream, and as a deputation from th creameries concerned was received last September, ther appears to be no necessity for a further interview on th subject at present.

Dental Charges to Approved Societies.

Mr. BROMLEY asked the Minister of Health if his attentio had been drawn to the charges made on approved societ members by dentists supplying artificial dentures and fo extractions; and, if so, whether, seeing that the charge so made were excessive in comparison with pre-war charge for similar supply and extraction, he would inquire if suc charges were in proper relation to the economic value o the dentures supplied and the services rendered.—S KINGSLEY WOOD replied: The charges referred to by th hon. Member were arrived at by direct negotiation betwee representatives of all types of approved societies and repr sentatives of the dental profession. They have bee voluntarily adopted by more than 95 per cent. of societie and my right hon. friend thinks, therefore, that they represer the best terms on which societies have found it possible t secure a satisfactory service for their members.

WEDNESDAY, FEB. 15TH.

Portsmouth Naval Hospitals.

Sir FREDERICK HALL asked the First Lord of the Admiralt what number of patients could be accommodated in th naval hospitals in the Portsmouth district; what was th average number of patients in residence; and what wa the annual cost of keeping up this accommodation.—M BRIDGEMAN replied: The only naval hospital in the Port mouth district is the Royal Naval Hospital, Haslar, Gospor The total peace accommodation of the hospital is officers, 8 men, 1059. The average number of cases daily und treatment during the last three years was 1927, 386; 192 381; 1925, 338. The annual cost of the hospital durin the last three years (ending Sept. 30th in each case) was a follows: 1926–27, £105,419; 1925–26, £106,406; 1924–2 £104,377.

International Opium Convention.

Mr. CAMPBELL asked the Secretary of State for Foreig Affairs whether the International Opium Conventio signed at Geneva in February, 1925, had yet come int force; and, if not, how many ratifications were still require before the Convention became operative.—Mr. LOCKE LAMPSON replied: The Convention is not yet in force, a three out of the necessary seven ratifications by members o the Council of the League are still lacking.

Tinned Milk Production on the Continent.

Mr. JOHNSTON asked the Minister of Health why h sent a commission of persons to inquire into the sanita conditions in which tinned milk imported into this count from Holland and Denmark was produced; and why h had not instituted similar inquiries into the milk produc being imported from Switzerland and the United Stat of America.—Mr. CHAMBERLAIN replied: I sent the co mission to Holland and Denmark to ascertain what found tion there might be for allegations which had been ma that in those countries the sanitary conditions of mi production were inferior to those obtaining here, and th regulations less stringent. About 75 per cent. of the tot imports of condensed milk (including about 95 per cent. the imports of condensed skimmed milk) come from tho countries. A considerable amount of information is in th possession of my department as to the conditions of produ tion in the United States of America as a result of visi which have been paid to that country on other occasio by officers of this department. The quantities of condens

imported from Switzerland at the present time are ively insignificant.

No Children's Bill this Session.

scountess ASTOR asked the Home Secretary if it was osed to introduce during the present session a new ldren's Bill to amend the Children's Act of 1908.—V. HENDERSON replied: My right hon. friend much ets that, owing to the pressure of Parliamentary business, ll not be possible for him to introduce a Children's Bill session.

THURSDAY, FEB. 16TH.

Conditional Disability Pensions.

r. BROMLEY asked the Minister of Pensions the number en in receipt of conditional disability pensions, and the ber that had been in receipt of conditional pensions for years or more; and if he would consider the granting ese men life pensions at their present rate of assess-.—Major TRYON replied: The total number of men ceipt of conditional pensions on Dec. 31st last was t 146,000, of whom the great majority had been in pt of pension for four years or more. I agree with the Member about the desirability of making final awards on as this can fairly be done, but to make such awards out medical consideration of the individual cases would e in the best interests of pensioners.

Ex-Service Men and Neurasthenia.

r. STEPHEN asked the Minister of Pensions the amount per head to the Glasgow Parish Council for ex-Service suffering from neurasthenia and undergoing mental ment in the local authority institution.—Major TRYON ed: Cases of neaurasthenia for which the Ministry esponsible are not sent for treatment by the Ministry nstitutions belonging to the parish council. Where, ny other circumstances, the parish council charge for tenance of a pensioner, the average charge is, I am med, 25*s.* 9*d.* per week.

Scottish Pensioners and Hospital Treatment.

igadier-General CHARTERIS asked the Minister of ions the total number of cases from Scotland treated e Ministry hospitals at Bellahouston, Craigleith, and hall during 1926; whether there was any intention of ng any of these hospitals; and whether he would an assurance that a Ministry of Pensions hospital d be maintained in Scotland so long as the number of requiring treatment was not less than the number ed at the smallest similar hospital in England and s.—Major TRYON replied: The total number of cases ed at the three Ministry hospitals in Scotland—namely, houston, Craigleith, and Edenhall—in the course of ear 1926 was 3362. There has been a considerable n the number of pensioners requiring treatment since year, the number of in-patients on Feb. 10th last ng been only 226, as compared with 557 on the corre-ding date in 1926, a decline of more than one-half. hese circumstances the hospital accommodation in and has had to be considered and arrangements have made to close one of the three hospitals—namely, leith—at an early date. With regard to the last part e question, my hon. and gallant friend may rest assured we shall maintain hospital accommodation in Scotland e best quality that can be got, and under our own ol for as long as it is needed.

Salaries of County Medical Officers.

ptain CROOKSHANK asked the Minister of Health her he had consulted the Law Officers of the Crown regard to the action of his department in refusing to grants towards the salaries of county medical officers other medical persons unless such salaries were in d with the schedule of the British Medical Association, if so, with what result; whether he was aware of the sfaction felt by the Lindsey County Council with regard ch a case; and whether his action was now to be fied in view of the terms of the Trades Disputes and es Unions Act of 1927.—Mr. CHAMBERLAIN replied: eply to the first part of the question is in the negative, o the second part in the affirmative. As regards the part, I am at present unable to see that the Act to a my hon. and gallant friend refers has any bearing this matter.

Nutritive Value of Tinned Foods.

r. FENBY asked the Minister of Health whether, in of the increasing consumption in Great Britain of d foods, he would say what steps were taken to ensure they were sound; and what effect, if any, they had e national health.—Mr. CHAMBERLAIN replied: Tinned , in common with other foods, are subject to inspection they are offered for sale, and, in the case of imported odities, at the time of importation. They may be l and destroyed if they are found to be unsound or otherwise unfit for human consumption. I am advised that the nutritive value of tinned foods is, in general, comparable with that of other cooked foods.

Invalidings from Royal Navy.

Sir BERTRAM FALLE asked the First Lord of the Admiralty the number of naval ratings invalided from the Royal Navy between Jan. 1st, 1927, and Dec. 31st, 1927; the number in which the invaliding disability was accepted as attributable to service; the number of ratings invalided with tuberculosis during the same period; and the number of tuberculosis cases in which the invaliding disability was accepted as attributable to service.—Lieut.-Colonel HEADLAM (Parliamentary Secretary to the Admiralty) replied: The numbers are respectively: 1359 and 84; and 180 and 18. Royal Marines are included.

TUESDAY, FEB. 21ST.

Notification of Venereal Disease in Scotland.

Mr. BUCHANAN asked the Secretary of State for Scotland the number of towns, if any, in Scotland which had approached him for power to make venereal disease compulsorily notifiable; and if he intended to exercise his powers in this direction in any town.—Sir J. GILMOUR replied: Since August, 1921, resolutions in favour of the general principle of compulsory notification of venereal disease, in one form or another, have been submitted to the Scottish Board of Health by 29 burghal authorities, by combined venereal diseases authorities representing burghs in Ayrshire and Lanarkshire, and by the Convention of Royal Burghs. The Corporation of Glasgow at a deputation about a year ago also raised the question of compulsory notification. In present circumstances I do not consider that the exercise of such powers as the Board have under the Public Health (Scotland) Act, 1897, would be an appropriate method of dealing with the matter.

Mr. BUCHANAN asked whether, in view of the fact that certain Corporations were approaching the House for powers, it would not be better, before anybody was granted any powers, that full inquiry into the subject should be instituted by the Department?

Sir J. GILMOUR: No, Sir. Much the best way would be to allow the matter to be discussed in the House.

Mr. E. BROWN asked whether the Secretary for Scotland had not also received a number of strong protests against the suggested course of action?

Sir J. GILMOUR said that he had received communications both pro and con.

Mr. HARDIE asked if it was not against the best interests of Government, either national or local, to do things by piecemeal, such as dealing with one town rather than another. Was it not better to have a full review, and then to legislate?

The SPEAKER said that that was a matter to be discussed on the Bill itself.

APPEAL FOR THE LONDON HOSPITAL.—Lord Knutsford has made an appeal for £250,000 on behalf of this hospital, of which he is chairman. It took the form, in the first instance, of a letter to the newspapers, but, on Sunday week, it was broadcast. Two days later Lord Knutsford received 10,000 letters containing money in sums ranging from sixpence to £1500; a day later 18,000 letters were still waiting to be opened.

HOSPITALS AND CHANGING TIMES.—Sir Alfred Sargeant, J.P., presiding, on Feb. 10th, at the annual meeting at Hove of the Brighton and Hove Dispensary and Hove Hospital—the hospital being a branch of the very old-established dispensary—made some pointed remarks on the changing times in connexion with such institutions. From the wealthy borough of Hove, in direct subscriptions to its hospital, only £600 was received during 1927, and Sir Alfred Sergeant, remarking on the fact that the whole character of Hove had changed in the last 30 years, said: "In the old days there were people living in their own houses in our avenues who had lived here for a great many years and had a civic sense—a sense of their duty to the community and their town—and supported the local institutions. Now, unfortunately, we live in flats, and a good many people come here for only two or three years. They don't get rooted in the place; they don't realise their responsibilities, and charitable institutions suffer considerably from that point of view alone. Our endeavour should be not only to ask people for subscriptions, but to instil into them a higher sense of duty to the town." Sir Alfred Sergeant went on to deplore the way they had to get money for hospitals—a half-crown ticket on the chance of securing a freehold house or a motor-car—and expressed the hope that the time would come when they could dispense with tombolas, or even entertainments, and that there would be such a succession of donors and subscribers that their institutions would be kept up as in the past.

Medical News.

THE EUGENICS SOCIETY.—The Galton Memorial Dinner was held under the auspices of the Eugenics Society on Feb. 16th at the Rembrandt Hotel, Brompton, S.W., when Major Leonard Darwin, President of the Society, supported by the Vice-President, Sir Bernard Mallett, presided over a representative gathering. After the dinner, the Galton Lecture was delivered by Mr. C. J. Bond, whose work in eugenics is of particular interest to the medical profession as having had its origin in his experience as a surgeon. His lecture was an important statement in respect of the national need for the organised study of eugenics, and at its conclusion he urged that the medical profession should coöperate in that study more generally and at the same time more closely than is at present the case. The lecturer's appeal was supported by Major Darwin, who outlined the work of the Eugenics Society and warned his audience that national decay could only be averted by individual as well as national effort. Sir Arthur Keith and the Bishop of Winchester respectively proposed and seconded a vote of thanks to the lecturer, when the words of the former had a wide message for the general practitioner in support of the plea for medical coöperation in the work of national eugenics. He affirmed that it was in the countryside rather than in urban areas that the study of eugenics could best be carried on, and he sketched the value to any national stocktaking, with respect to physical and mental equipment, that would accrue from a properly conducted system of education by which the whole population, and not only those below a certain income level, would receive their training in common. Among the guests present at the dinner were Dr. H. H. Dale, secretary of the Royal Society, Prof. Major Greenwood and Dr. D. R. Wilson from the Medical Research Council, Dr. C. S. Myers, director of the National Institute of Industrial Psychology, Lord Dawson, Colonel Fremantle, M.P., the Right Hon. William Graham, Sir William Beveridge, Dr. T. H. C. Stevenson, of the General Register Office, Miss Olga Nethersole, Dean Inge, Mr. Wheler Galton, Mrs. Neville Rolfe, Prof. MacBride, Captain Pitt-Rivers, Sir Dawson Williams, and Sir Squire Sprigge.

LECTURES ON CANCER.—The Yorkshire Council of the British Empire Cancer Campaign has arranged a series of three lectures, open to members of the medical profession without fee, to be given at the Medical School, Leeds, on Wednesdays, at 3.30 P.M. On March 7th an introductory address will be given by Sir Berkeley Moynihan; on April 4th Prof. G. E. Gask will speak on Radium in the Treatment of Malignant Disease; and on May 9th Prof. G. Grey Turner will speak on Cancer of the Rectum. Tea will be provided at 4.30 P.M., and practitioners who intend to be present are asked to inform the secretary of the campaign at 47, Park-square, Leeds, at least two days before each lecture.

BELFAST HOSPITAL FOR SICK CHILDREN.—The fifty-fifth annual meeting of this institution was held at the hospital on Feb. 7th. The reports showed that the work had increased largely during the year, and the financial report showed a considerable credit balance. The pressure upon the accommodation of the hospital has so far outrun the resources of the institution that a scheme of rebuilding has become an urgent necessity, and building operations will be begun in a few months. An appeal to the public for the necessary funds has met with a prompt and generous response. At the beginning of the year the rebuilding fund stood at £24,000, and at the end of the year this figure had risen to £44,000. The new hospital will be modern in every respect and will provide accommodation for 66 intern patients and a greatly enlarged extern department. It will be capable of quick and easy expansion to a hospital containing accommodation for 120 or more intern patients. The cost of the present plans will be not far short of £100,000.

Prof. J. A. Lindsay, who presided at the meeting, pointed out that hospital policy was receiving more attention and intelligent discussion at the present time than at any previous period. These discussions had emphasised three points: (1) That hospital accommodation was everywhere inadequate, that the demand for the institutional treatment of disease was steadily growing, and that hospitals ought to receive adequate financial support to enable them not only to provide the best facilities for the treatment of patients but also to further research and medical education. (2) That there ought to be more coöperation and mutual understanding between hospitals, so as, on the one hand, to prevent overlapping, and, on the other hand, to secure that the field of hospital service was adequately filled. (3) That more provision should be made for the middle classes, who provide most of the financial support for the voluntary hospitals but who have only a meagre share in their benefits.

FEDERATION OF MEDICAL AND ALLIED SERVICI
A meeting of the Council of Industrial Medicine will be
on Friday, March 2nd, at 5.30 P.M., at 12, Stratford-p
London, W. 1, to consider (1) the treatment of indu
accidents, and (2) the value of adequate treatme
industrial rheumatism.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASS
TION.—This association will hold a dinner on Satu
March 17th, at 7.30 for 7.45 P.M., at the Savoy Hotel, Lo
General Sir Hubert Gough will be the principal guest.
hon. secretary is Dr. F. R. Holmes Meyrick, 59, Kensin
court, W. 8.

SOCIETY FOR THE STUDY OF INEBRIETY
meeting will be held in the rooms of the Medical Socie
London, 11, Chandos-street, Cavendish-square, London
on Tuesday, April 17th, at 4 P.M. Mr. Cecil Chapman
metropolitan police magistrate to the Westminster P
court, will open a discussion on Alcoholism and Crime

HUNTERIAN SOCIETY.—This society has
invited by the Hunterian Society of St. George's Ho
to hold a joint meeting to commemorate the bicent
of the birth of John Hunter. The meeting will be h
the board room of the hospital on Thursday, March
at 9 P.M., and will take the form of a conversazione,
addresses being delivered by Sir Humphry Rollestor
Sir Crisp English.

SOCIAL HYGIENE SUMMER SCHOOL.—The Bi
Social Hygiene Council has arranged to hold a su
school at Westminster College, Cambridge, from July
to August 2nd. The school is open to all interested in
problems, and addresses will be given, amongst othe
Dr. H. Crichton Miller, Dr. Letitia Fairfield, Mr.
Turner, Prof. Winifred Cullis, Dr. I. Feldman, Colonel
Harrison, and Dr. Margaret Rorke. Further informatio
be had from the secretary at Carteret House, Car
street, London, S.W. 1.

NDUSTRIAL PSYCHOLOGY.—The National Institute ndustrial Psychology, founded in 1921, has received an ıymous gift of £4000 towards the cost of new premises. work of the institute has so much increased that larger ıises with well-equipped psychological laboratories are ıtial.

. R. WILSON MEMORIAL PRIZE.—A Sidney Rawson on Prize, of the value of £50, is offered for the best ırch work on inhalation anæsthesia carried out by a en of the British Empire before Dec. 1st, 1928. Further iculars may be had from the secretary of the *British nal of Anæsthesia*, at Ainsdale, Palatine-road, Withon, Manchester.

NDUSTRIAL HEALTH EDUCATION SOCIETY.—The ıal meeting of this Society will be held on Tuesday, 28th, at 4 P.M., at the house of the Society of Medical ers of Health, 1, Upper Montague-street, Russell-square, lon, W.C. Sir William Haldane will preside, and among peakers will be Sir Thomas Horder, Sir Thomas Oliver, Mr. Ben Turner, President of the Trades Union Council.

ECKETT HOSPITAL, BARNSLEY: NUMBER OF DENTS.—The Duke of Northumberland on Feb. 8th ed the new wing of the Beckett Hospital and Dispensary arnsley. The people of Barnsley and the neighbour- have provided over £16,000, but over £10,000 is still ired to meet the cost of the new wing and also a sum ient to bring an income of £5000 a year to endow the wing. Mr. Herbert Smith, president of the Miners' ration, furnished figures showing the demand for ital facilities. Every 2½ minutes a workman in the s was seriously injured, and over 35 per cent. of them ved hospital treatment in 1920. Out of 139,963 persons ed in factories and workshops more than 40 per cent. ht hospital relief, and also, in 1926, out of 133,885 people ved in road accidents over 55 per cent. were taken spital.

ENTRAL COUNCIL FOR DISTRICT NURSING IN DON.—The annual meeting of the Council was held eb. 23rd, when the report for 1927 was presented. report showed that there had been a gradual increase strict nursing in Middlesex. The executive committee, hich the Rev. J. Scott Lidgett is chairman, and Miss L. Puxley, vice-chairman, reported that grants to the nt of £4595 had been distributed among 49 district ng associations, and that £3000 had been received the London parochial charities, £100 from the trustees abody Donation Fund, £60 from the trustees of Guinness t for Dwellings, and £585 from the Ministry of Health. also reported on an arrangement by which the Mutual erty Insurance Co. provides free nursing services for olicy-holders, and stated that the effect of this arrange- on the district nursing associations organised on ident lines was being watched. It was announced that conference called to consider the new regulations con- ng the admission of scarlet fever and measles cases letropolitan Asylums Board hospitals, it had been d that the home nursing of scarlet fever could be rtaken with careful precautions, provided that the es were not in attendance on maternity cases.

HE LATE DR. ELIZABETH RUSSELL.—Dr. E. D. ell, who died at sea on Feb. 12th, had for the last five s lived an active professional life as assistant physician ıe Pretoria Mental Hospital, although suffering from etes mellitus. The disease was already at such an nced stage when insulin first became available that it ed scarcely possible that she would survive the journey South Africa to receive treatment in this country. results—in those early days of insulin therapy—seemed culous, and she courageously determined to continue ork, leading an insulin life, which at that time entailed from absence of standardisation. Dr. Russell not only ed on routine work, but found energy to conduct and ish, jointly with Dr. A. Pijper, important researches into athological aspects of mental disease. In her leisure rove a car and played tennis, letting her special require- s interfere little—perhaps too little—with her normal l life. "She was a lovable person," writes a medical d, "steadfast, plucky, and popular with her colleagues etoria and with her fellow students in the University of Town and at the Royal Free Hospital. Her friends will remember with pride her successful fight against adverse itions." Dr. Russell was the daughter of Mr. W. A. ell, well known in educational circles in South Africa. ntered the Royal Free Hospital in 1916 and qualified .R.C.S. Eng. in 1918, later taking the D.P.H. Her ger sister is also a member of the medical profession.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Feb. 27th.—8 P.M., ODONTOLOGY. Paper: Mrs. Lilian Lindsay: Dentistry as One of the Fine Arts. Casual Communication: Mr. Alvan T. Marston: A Case of Necrosis of the Mandible.

TUESDAY.—5 P.M., MEDICINE. Paper: Dr. H. L. Tidy: The Hæmorrhagic Diathesis. Members having cases to show are requested to communicate with the honorary secretaries without delay.

THURSDAY, March 1st.—8.15 P.M., TROPICAL DISEASES. Paper: Dr. Andrew Balfour: Health Lessons from Bermuda.

FRIDAY.—5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Cases and Specimens will be shown by Dr. Green, Mr. Ridout, Mr. Bell Tawse, Dr. Syme, and others. Communication: Dr. Graves and Dr. Pickworth: Sinusitis in the Ætiology of Mental Disorder. 8.30 P.M., ANÆSTHETICS, OBSTETRICS. Discussion on Anæsthesia in Obstetrics. Openers: Dr. J. Blomfield and Mr. H. A. Richards (Anæsthetics), Mr. Eardley Holland and Mr. W. Gilliatt (Obstetrics). Mr. H. Edmund G. Boyle (Anæsthetics) and Dr. Herbert R. Spencer (Obstetrics) have also promised to speak.

SATURDAY.—10.30 A.M., OTOLOGY. (Cases at 9.30 A.M.) Paper: Dr. Isadore Müller (Carlsbad): Meditations on Vertigo Based on Experience. Cases and Specimens will be shown by Dr. M. Sourasky (introduced by Mr. Kisch) and others.

HUNTERIAN SOCIETY.

MONDAY, Feb. 27th.—9 P.M. (at the London Mansion House), Dr. A. Feiling: Sciatica: Its Varieties and Treatment. (Hunterian Oration.)

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.

MONDAY, Feb. 27th.—8.30 P.M., Discussion on the Scope of Surgery in the Treatment of Chronic Rheumatoid and Osteo-arthritis. To be introduced by Mr. Max Page, followed by Mr. Henry Platt.

WEDNESDAY.—9 P.M., Dr. F. J. Poynton: Rheumatic Heart Disease in Childhood. (Lettsomian lectures (2).)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

THURSDAY, March 1st.—5 P.M., Dr. F. A. E. Crew: Individual, Familial, and Racial Inborn Differences in Respect of Immunities and Disease Resistance. (Milroy lecture (1).)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Feb. 27th, to SATURDAY, March 3rd.—FELLOWSHIP OF MEDICINE LECTURE, Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Dr. Neill Hobhouse: Amentia in Relation to Cerebral Disease and Abnormality.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Wed., 5 P.M., Clinical demonstration by Dr. C. B. Heald on Cases Treated by Electrotherapy.—SAMARITAN HOSPITAL FOR WOMEN, Marylebone-road, N.W. Wed., 2.30 P.M., Clinical Demonstration by Mr. Aleck Bourne. The above are free to members of the medical profession.—QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford, E. Second week of a course in medicine, surgery and the special departments—THE NATIONAL HOSPITAL, Queen-square, W.C. Special course in Neurology. Lectures, demonstrations, including pathology.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, Feb. 27th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY, March 1st.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10. 30 A.M., Throat, Nose, and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Monday and Thursday at 2.30 P.M., there will also be special demonstrations of medical and surgical cases by Dr. J. B. Alexander and Mr. H. W. Carson respectively.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.

THURSDAY, March 1st.—4 P.M., Mr. M. S. Mayou: Some Common Disorders of the Eye in General Practice.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Feb. 28th.—5 P.M., Dr. Wilfrid Fox: Cutaneous Syphilis (1).
THURSDAY, March 1st.—5 P.M., Dr. Wilfrid Fox: Cutaneous Syphilis (2).

NATIONAL HOSPITAL, Queen-square, Bloomsbury.
MONDAY, Feb. 27th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3,30 P.M., Dr. Riddoch: Trigeminal Neuralgia.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: The Psychoneuroses (1).
THURSDAY, March 1st.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Pituitary Tumours (2).
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Cerebral Abscess.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.
THURSDAY, March 1st.—4 P.M., Mr. H. A. T. Fairbank: Surgical Treatment of Poliomyelitis.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, Feb. 28th.—3.15 P.M. (at the Royal Chest Hospital), Dr. H. E. Symes-Thompson: Intra-Thoracic Tuberculosis in Childhood.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
THURSDAY, March 1st.—4.30 P.M., Dr. David Thomson: Common Infection of the Genito-Urinary Tracts.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Feb. 29th.—4.30 P.M., Sir Robert Armstrong-Jones: Present Legal Aspects of the Treatment of the Insane and the Mentally Defective.

PEOPLE'S LEAGUE OF HEALTH.
WEDNESDAY, Feb. 29th.—6 P.M. (at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, W.), Dr. E. Mapother: Mind and Body.
THURSDAY, March 1st.—6 P.M., Dr. Leslie J. Harris: Vitamins, Their Significance for the Man in the Street.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
FRIDAY, March 2nd.—4.15 P.M., Dr. A. H. Holmes: Demonstration of Medical Cases.

ST. MARY'S HOSPITALS, MANCHESTER.
FRIDAY, March 2nd.—4.30 P.M., post-graduate lecture (at the Whitworth-street West Branch), Dr. Addis: Breech Presentations.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, March 2nd.—3.30 P.M. (in the Royal Infirmary), Dr Hallam: Dermatological Cases.

Appointments.

EDWARDS, N. L., M.B., Ch.B. Manch., F.R.C.S. Eng., has been appointed Hon. Gynæcological Surgeon, Derby Royal Infirmary.

LLEWELLIN, DOROTHY M., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer of Health and Assistant Schools' Medical Officer, Mountain Ash District.

Manchester Royal Infirmary: HOLT, R. L., F.R.C.S. Eng., Assistant Resident Surgical Officer; WALKER, G. R., M.B., Ch.B. Manch.; ABRAHAM, R. S., M.B., Ch.B. Manch.; MARTIN, H. E., M.B., Ch.B. Manch., and CRETNEY, E., M.B., Ch.B. Manch., House Physicians; NUTTALL, J. R., M.B., Ch.B. Manch., APPLETON, S. K., M.B., Ch.B. Manch., WARD, E., M.R.C.S., L.R.C.P. Lond., SYKES, C. E., M.B., Ch.B, Manch., WATKINS, H. K., M.B., Ch.B. Manch., and ROBINSON, M., M.B., Ch.B. Manch., House Surgeons; KAUFMANN, Miss P. I., M.B., Ch.B. Manch., Junior Assistant House Surgeon; TAYLOR, S. N., M.B., Ch.B. Manch., Resident Medical Officer, Barnes Convalescent Hospital, Cheadle; SOMERFORD, A. R., M.B., Ch.B. Manch., Assistant Medical Officer (non-resident), Out-patients' Department; MARSHALL, Miss, M.B., Ch.B. Manch., Clinical Assistant (non-resident), Surgical Out-patients' Department; ROBERTS, R. I., M.R.C.S., L.R.C.P. Lond., Second Surgical Registrar (non-resident).

Certifying Surgeons under the Factory and Workshop Acts: GORDON, G. S., M.B., B.Ch. Glasg. (Kilwenning, Ayr); HICK, R. H. P., L.R.C.P. Lond., M.R.C.S. (Bracknell, Berks); HETHERINGTON, W. M., M.B., Ch.B. Edin. (Wetheral, Cumberland); MATHEWS, R. G., B.M., B.Ch. Oxf. (Kirby Lonsdale, Westmorland); STEPHEN, N. M., M.B., Ch.B. Edin. (Peasenhall, Suffolk).

Vacancies.

For further information refer to the advertisement columns.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.

Bristol City and County of.—Chief Asst. M.O.H., &c. £800. Also Asst. M.O.H. £750.

Burton, Devonshire Hospital.—Asst. H.P. At rate of £150.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. At rate of £75.

Eastbourne, Princess Alice Hospital.—Jun. Res. H.S. At rate of £100.

East Islington Mothers' and Babies' Welfare Centre, 10, Drayton Park, N.—M.O.

Great Yarmouth General Hospital.—H.S. £150.

Grove Park Hospital, Lee, S.E.—Jun. Asst. M.O. £500.

Hertford County Hospital.—Res. Surg. O. £250. Also At rate of £150. Also Hon. Anæsthetist.

Hospital for Consumption and Diseases of Chest, Brompto—Res. M.O. £350.

Hospital for Sick Children, Great Ormond-street, W.C.—Pathologist and Research Fellow. £450. Also Jun. O. (part-time). At rate of £75.

King's College Hospital, Denmark Hill, S.E.—Two Jun. Surg

Leamington Spa, Warneford General Hospital.—Res. H.S.

Leeds University, Safety in Mines Research Board.—Physiol £300.

Leicestershire County Council.—Asst. M.O.H., &c. £600.

Lincoln, City and County Borough of.—M.O.H. £1000.

Liphook, Hants, King George's Sanatorium for Sailors.—M.O. At rate of £200.

London County Council.—Temp. Asst. M.O. 30s. per sessio

London Temperance Hospital, Hampstead-road, N.W.—M.O. At rate of £175.

Manchester Ear Hospital, Grosvenor-square, All Saints.—H.S.'s. At rate of £150 and £120.

Manchester Royal Children's Hospital, Pendlebury.—Surg. O. and Res. M.O. Each at rate of £125.

Manchester Royal Children's Hospital, Gartside-street.—M.O. At rate of £140.

Miller General Hospital for South-East London, Greenwich-S.E.—Hon. P. to Special Dept. for Children. Also M.O. At rate of £250,. Also H.P. At rate of £125.

Northampton General Hospital.—H.P., two H.S.'s and Asst. H.S.'s. Each at rate of £150.

Nottingham and Midland Eye Infirmary.—H.S. £200.

Nottingham General Hospital.—H.S. At rate of £150.

Perth, James Murray's Royal Asylum.—Asst. Phys. £300.

Plymouth, Homœopathic and General Hospital.—H.S. At of £100.

Radcliffe-on-Trent, Notts County Mental Hospital.—Med. £1000.

Royal Waterloo Hospital for Children and Women, Wat road, S.E.—Hon. Med. Reg.

St. George's Hospital Medical School, Hyde Park Corner, S.—Research Worker. £500.

St. Mary Abbots Hospital, Marloes-road, Kensington, Asst. Med. Supt. £450.

St. Peter's Hospital for Stone, &c., Henrietta-street, Garden, W.C.—H.S. At rate of £75.

Salisbury General Infirmary.—H.S. £150.

Samaritan Free Hospital for Women, Marylebone-road, N.—H.S. At rate of £100.

Smethwick County Borough.—Pupil Assistant.

Southampton, Royal South Hants and Southampton Hospit—Cas. O. £120.

Stoke-on-Trent, City of.—M.O. of Venereal Dis. Centres.

Torquay, Torbay Hospital.—Hon. Med. O. for Ear, Nose Throat Dep.

West London Hospital, Hammersmith, W.—H.P. and two H. Each at rate of £100. Hon. Med. Reg. £100. Also Anæsthetist.

Whipps Cross Hospital, Whipps Cross-road, Leytonstone, Asst. M.O. £300.

Willesden Municipal Hospital, Brentfield-road, Neasden, N.—Res. M.O. £150.

Worksop, Victoria Hospital.—H.S. At rate of £170.

A vacancy for Certifying Factory Surgeon is announce Sutton-in-Ashfield (Nottinghamshire).

The Secretary of State for the Home Department gives n of a vacancy for a Medical Referee under the Work Compensation Act for the Orkney District (Sheriffdo Caithness, Orkney and Shetland). Applications sh reach the Private Secretary, Scottish Office, Whit London, not later than March 14th.

Births, Marriages, and Deat

BIRTHS.

BERRY.—On Feb. 17th, at Glenthorne, Watford, the wi Dr. H. Berry, of a son.

HAYDON.—On Feb. 18th, at Melton Mowbray, the wi Leonard John Haydon, M.R.C.S., of a daughter.

JONES.—On Feb. 13th, at Deddington, Oxon., the wif George Horatio Jones, M.R.C.S., of a son.

NEAME.—On Feb. 13th, at Portland-place, W., the wif Humphrey Neame, F.R.C.S., of a son.

ROSE.—On Feb. 10th, at Lansdowne House, Romsey, H the wife of Edward S. Rose, M.R.C.S., of a son.

WILSON.—On Feb. 18th, at Moselle House, High-road, To ham, N., the wife of Archibald Wilson, O.B.E., M.C., Ch.B., of a daughter.

DEATHS.

GUTHRIE.—On Feb. 18th, at The Crossways, Tunbridge W Thomas Clement, M.D., M.R.C.S., aged 60.

JEPSON.—On Feb. 12th, at Palliser-road, W., Victor B Jepson, M.R.C.S., L.R.C.P., aged 59.

PHILLIPS.—On Feb. 11th, at Twyford Abbey, London, Surg Captain John Elphinstone Hood Phillips, R.N. (retd.).

POCKETT.—On Feb. 18th, 1928, at 259, Hainton-ave Grimsby, Lewis Walter Pockett, M.D., F.R.C.S., L.R. L.S.A. Cremated Golders Green, Wednesday, Feb. 2

SHEPERD.—On Feb. 15th, at "Stradbally," Lansdown Cheltenham, Robert John Sheperd, L.R.C.P., L.R. aged 76.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notic Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

CARE OF THE SCHOOL-CHILD.

IN an address on child guidance delivered before the ld Study Society on Feb. 16th Sir Humphry Rolleston d that the word "education," which connoted preparation future life, should be used to include the development of h physical and mental capacities, for these were closely er-related, and must be wisely balanced. The difficulty arranging the routine of school-life was that children differed in their individual capacities, whilst from the nt of view of the school it was necessary that there should a uniform and systematic plan, and individual license st be comparatively small. The necessary limitations the school had to be compensated for by the freedom he holidays, and the urgent need for these holidays was en shown by the way in which children flagged in the nd half of the term. During adolescence there was an erse ratio between physical growth and mental efficiency, when a child was growing rapidly its mind did not p pace. Schoolmasters often reported about the age of erty that a child was fidgety, inattentive, and could do h better; but if a boy was not doing well, the fact ld be accepted philosophically by the parents as an cation that he was growing, and not as a sign of vice. s did not develop at the same rate, and the rate at which blossomed out was no assurance of how long they would inue to bear fruit. It was important to remember that young, however callous and defiant they might appear, really extremely sensitive and impressionable, and r self-respect and spirit were often worn down by depre- ry comparisons, and by the constant snubs of school- ters and parents. There was always a tendency to up to the character one was given, and sympathy and erstanding was seldom wasted upon backward children. was a serious matter, continued Sir Humphry, to curtail necessary hours of sleep of growing boys and girls, these should be 11 hours for a child up to the age of years, and 9½ hours up to the age of 17, both these ma being increased during the winter months. Insuffi- cy of sleep, tantamount to overwork, favoured mental ability and rendered a child liable to the inroads of ase. The young, clever boy who was high in the school his years, ought to sleep in a dormitory for boys of his age. Better results had also been obtained in the er of winning scholarships by reducing the amount me that boys were supposed to be working; the character he work done and the health of the pupils were also oved by prolonging the rest periods between the hours ork. As far as possible all out-of-school work should be ded, and punishments which involved keeping children he school-room were quite wrong. Discipline had to be tained, and he considered that corporal punishment a perfectly right correction so long as a master, before ting it, made full inquiries; the immediate boxing of and twisting of arms should, of course, be abolished. fact that children developed at different rates made question of over-pressure and over-work in schools a ult one. The effects of over-pressure of the brain more important than the effects of over-pressure of the , and whereas it was difficult to over-strain a perfectly hy child by physical exercise, there was much less ve power in the nervous system.

the subsequent discussion Dr. Letitia Fairfield said that ngland she thought it extremely rare to see cases of over- in a child, and they were usually associated with some ional disturbance outside school life. It was interesting te how retardation at school might spring from remote ional causes. In America, however, things were different. the beginning of their school lives children brought reports to their parents which were taken extremely usly, and promotion in the schools was automatic, a remaining behind being in disgrace. The gay little er of our schools who did not want to learn was severely ng in American schools.

"METALIX" X RAY TUBES.

have received from Philips Lamp, Ltd. (145, Charing -road, London, W.C. 2), an illustrated brochure showing arious types of "Metalix" X ray tubes which are now able. A remarkable feature of the brochure is that it illustrations of X ray apparatus by a number of ent manufacturers. From their design "Metalix" facilitate protection to the operator, an advantage ich manufacturers have not been slow to avail them- s. The benefit is shared by the purchaser, for the of putting heavy protective material on moving parts neant a big outlay. The time since the introduction ese tubes may be too short to pass any final verdict eir lasting qualities, but extended use by medical men sts that they are coming up to expectations.

THE INFLUENCE OF PROSPERITY ON HEALTH.

AT a meeting of the Royal Statistical Society on Feb. 21st Dr. T. H. C. Stevenson, of the General Register Office, read a paper on Vital Statistics of Wealth and Poverty. Many attempts, he said, have been made to estimate the influence upon health of prosperity and the lack of it, but the extent of our ignorance of the subject attests the difficulties of its investigation. The method most commonly employed has been the comparison of returns for complete populations selected as representing wealth and poverty. But the samples so secured are very far from pure, or free from influence by other factors than that under investigation. If the contrasts in wealth, and, what is probably quite as important in its influence on health, culture, are to be obvious, the numbers available for examination will be limited; and on the other hand, if the field of investigation is extended the difficulty of assessing degree of local wealth and culture becomes formidable. Classification of individuals by income is not possible under present conditions in this country, though it has been employed on a very limited scale in some American investigations. Estimation of poverty by housing conditions is very unsatisfactory, as bad housing is only one of the handicaps of poverty, so that it is impossible to determine how far the excess of mortality associated with bad housing is due to poverty and how far to the direct effects of overcrowding and other factors.

Even if full details of income were available, these in themselves would not provide an ideal basis of classification, as it is probably rather the cultural associations of wealth which promote longevity than wealth itself. The clergy are, for the most part, poorly paid, but they are singularly healthy. The method which Dr. Stevenson advocated as on the whole best meeting the conditions to be considered is that of inferring social position from occupation. By this means regard can be paid to (average) culture as well as income, and the total occupied population can be included in the inquiry. The results attained by a scheme based on these lines are described in the recent report of the Registrar-General on Occupational Mortality during 1921–23, and the regularity and consistency of the graduation so obtained of mortality from various causes is held to be in itself evidence of the success of the social classification so arrived at. Dr. Stevenson quoted instances of such regularity, mortality from many forms of disease increasing without interruption from a minimum in the highest to a maximum in the lowest social class. Respiratory diseases, including phthisis, furnish, he said, the most pronounced examples of this type of distribution, which tends to be reversed for diseases of the digestive system, and for diabetes in later life, mortality from appendicitis increasing without interruption from a minimum for the lowest to a maximum for the highest of the five social classes distinguished. The case of cancer is especially interesting. Mortality from this cause follows the usual type of social distribution, being lowest in the highest, and highest in the lowest, section of society. But this gradation is found to apply to cancer of certain sites only, mortality from the remainder being much the same for all classes. The graded sites, which are responsible for about half the total deaths (in males, for whom alone the requisite occupational information is available), includes the upper alimentary canal from mouth to stomach inclusive, the skin, and the larynx. It would therefore appear that cancer of these sites is largely preventable, though the factors determining its differential incidence will have first to be recognised.

In conclusion Dr. Stevenson suggested certain further uses for a social classification based on occupation, including investigation of the tendency of various sections of society to increase or decrease and be replaced by others.

RECIPES FOR LIVER DIET.

THE fact that those undergoing liver regimen have to eat large quantities of the food makes it imperative that as much variety as possible should be found in the ways of serving it. We have already referred to a collection of Irish recipes [1] and a booklet has now reached us entitled "Liver: Nutritive Value and Ways of Serving" (Department of Home Economics, Institute of American Meat Packers, 509, South Wabash-avenue, Chicago), which contains 40 American recipes for serving this article of food, adapted to the three principal meals of the day, all of which can be used in the home, and most of which are applicable to hospitals and institutional dietaries. Two examples may be given; the first is for baked liver, Swedish style, the second for stuffed cabbage leaves:—

Ingredients.—1½ lb. beef liver; flour to dredge; salt, pepper; 1 cup cream or milk; 2 apples, sliced; 6 prunes, cooked and stoned; 2 tablespoons butter; 3 slices bacon. *Method.*—Select a thick piece of liver. Soak over night or for several hours in a marinade dressing or in buttermilk. Cut liver on thick side to form a pocket, sprinkle cavity with salt and pepper, then fill with fruit and broken bits of butter. Sew or skewer

[1] THE LANCET, Jan. 14th, p. 113.

liver together. Make several cuts about ¼ inch deep on outer top surface of liver, dredge with flour, wrap with strips of bacon, and skewer into place. Put in a baking dish, add ½ cup water, and bake 2 hours in a moderate oven (325° F.), basting occasionally. When done, place liver on a platter and garnish. Thicken liquid in pan, add cream or milk and seasonings, and serve with meat.

Ingredients.—1 cup liver, chopped or ground; 2 tablespoons bacon fat; 1 cup tomato juice or stock; 1 cup cooked rice; 1 beaten egg; ½ teaspoon celery salt; 1 teaspoon salt; dash of nutmeg or cinnamon; 1 small onion, minced; 10 to 12 cabbage leaves. *Method.*—Remove the outer leaves of a cabbage head, wash, then cover with boiling water and cook for 3 to 5 minutes, or until the leaves begin to look transparent. Combine the liver, rice, beaten egg, bread crumbs, 1 tablespoon each of bacon fat and onion, and seasonings. Mix thoroughly. Remove cabbage leaves from water, drain, and on each leaf place a large tablespoonful of the liver mixture. Roll and fold each cabbage leaf, and then tie with string or fasten with toothpick. Melt rest of bacon fat in a deep frying pan, brown slightly the rest of the onion and lay on it the filled cabbage leaves. Pour over them the stock or tomato juice, cover, and cook slowly over a low fire 1 hour or bake in a moderate oven (375° F.) 45 minutes. If fat is limited in the diet, omit it in the recipe and scant the amount used for browning.

MIDDLE-AGED SPRINTING.

Dr. F. E. Fremantle, M.P., has an interesting note in a recent issue of the *Journal* of the London Athletic Club upon the health value of running as a recreation. He describes the cross-country runs which he and his contemporaries at Guy's Hospital took regularly, and he gives it as his experience that all the men sufficiently fit to undertake these runs benefited much by them, although he allows that the physical strain was exacting when the arduous life of the medical student had to be conducted at the same time. Contemplation of the breakdown of friends in middle life leads him to the reflection that they might have kept their health if they had learned early the value of cross-country running, indulged in it reasonably and practised it, or some analogous exercise, throughout life. The value of a daily sprint of a hundred yards is alluded to as keeping the heart trim and the circulation in good order, but we are sure that he would recommend those of his middle-aged friends who have already begun to show signs of circulatory trouble to avoid this particular form of exercise whenever possible—never, in short, to run for a train.

NEW PREPARATIONS.

WE have received samples of *Tricalcine* from the laboratory of Dr. Perraudin in Paris (Agent: Wilcox, Jozeau et Cie, Great St. Andrew-street, London). The drug has been designed to supply certain mineral elements necessary to human alimentation when deficiency is diagnosed, particularly if it can be traced to faulty dietetic methods. The calcium preparation is supplied pure or in association with adrenalin, with methylarsenate of soda, or with fluoride of calcium, according to the condition for which the recalcifying treatment is made. Great claims are made for the remedy in assisting the normal formation of and subsequently in preserving the teeth, and there would seem to be many conditions in which an intelligent trial of the preparation might be made.

Hæmatopan.—This drug is prepared in the laboratory of Dr. A. Wolff, of Bielefeld (Agent: Mr. James Wandrum, Stow-street, Paisley), and is a combination of hæmoglobin and malt. It has, we believe, been procurable for over 20 years, but recently a good many reports of its beneficial effects in malnutrition have been received, with the result that an increased interest in the preparation is being manifested. Various combinations of hæmatopan with a small percentage of arsenic, with potassium bromide, calcium lactate, guaiacol, colloidal silica, and iodine are also prepared in accordance with the indications of the case.

Radiostol, which is now prepared by British Drug Houses, Ltd. (Graham-street, City-road, London), is an irradiated ergosterol and should be of service in making good dietetic deficiencies, especially in cases of rickets. It is prepared in bottles of 50 tablets, each tablet containing an exact quantity of radiostol, while it is claimed that the original vitamin D content is maintained. The radio-ergosterol is also issued in solution where the antirachitic activity is estimated at 50 times that of cod-liver oil. The preparation is clearly one upon which systematic reports might be made with profit.

We have received from Messrs. Coates and Cooper, of Great Tower-street, London, acting as agents for Messrs. Reed and Carnrick, of Jersey City, U.S.A., samples of *Peptenzyme* in what is termed "elixir form." The preparation is designed to be used as a vehicle for noxious and distasteful drugs with which it is usually readily miscible. It is neutral in reaction, low in alcoholic content, and is stated, as its title conveys, to contain certain enzymes valuable in digestion.

A HOSPITAL PHARMACOPŒIA.

THE Pharmacopœia of the Paddington Green Child Hospital, revised last December, has been reissued as a volume of 19 interleaved pages. Formularies of this reflect more or less faithfully the accumulated tradi of a serviceable routine. The detached reader pickin the volume before us may pardonably query such not happy pieces of latinity as Collyrium Borozinci and P Rhei cum Sodio, and may wonder what is designate Oleum Dulce; but in all probability such cruxes do exist for members of the hospital staff. The book is con hensive in its scope, particularly as to its lotions, mixt and ointments; it will be helpful if in future edition age for which the dose of each internal medicine is presc is indicated.

CHILDREN'S DECORATIONS FOR CHILDREN WARDS.

THE *World's Health* (the organ of the League of Cross Societies) for February tells us that the childr New York schools (ages 10–14) were asked to sen sketches of the pictures they would like to look at if were sick in hospital wards. Generally they favo illustrations of fairy tales or nursery rhymes. A thousand exhibited and 500 were selected as remarkable for c tones, mastery of design, and appeal to the imagin These will be used in the children's wards of the new m centre which is a-building in New York, and shou completed this year.

PROTEIN TREATMENT OF DRUG-ADDICTIO

WITH reference to an annotation with the above published in our last week's issue (p. 350), Dr. Stanford informs us that he referred to the treatment of drug-add with endocrine extracts in the annual report for Bay M Home for 1925, and has since been making experiment the method. The low blood pressure invariably fou drug patients, he says, and other symptoms sugg endocrine insufficiency, suggested the use of orchitic suprarenal extracts, and he has found them of consid value in maintaining the strength and tone of his pat Similar improvement has been noticed in a certain ty sufferer from alcoholism.

ALKALI RESERVE AND THE COMMON COL

"DYSPEPTIC" writes: I read with great interes paragraph on the common cold from your Ame correspondent last week (p. 370). I have been en free from colds for a great many years, but have suffer about the same length of time from a form of indig for which large doses of various alkalis have been presc Whether the theory put forth by Dr. Cheney is acce or not, I am prepared to be consoled by the though this continued treatment of the persistent digestive t is keeping at bay the common cold in my own case.

TWO USEFUL CONVALESCENT HOMES.

Catisfield House, Brighton.—The Catisfield Estate bequeathed by Miss Rose Greene to establish a convale home for gentlewomen of limited means, especiall those leaving hospital after an operation or acute i The home is run on the lines of a first-rate convale home, and when necessary, medical attendance and me are provided free of charge. There is accommodatio seven patients, and a charge of from 30*s.* to £2 a hea week is made, as the endowment is insufficient to pa whole expense of upkeep. The home has only been two years, but when it is better known it should cer be always full. Patients suffering from phthisis, cancer, infectious diseases, mental trouble, or drug are not admitted. Full particulars may be had fro Matron, Catisfield House, Sillwood-road, Brighton.

The Frederick Andrew Convalescent Home, West M is run on the lines of a private house in the country, to are admitted for three weeks at a time gentlewome require convalescence after recent illness or ope The stipulation is that they should be such as have t their own living. No charge is made for admissio patients pay their own laundry and telephone ch There is accommodation for 15 patients, each in a se bedroom. The home is not a holiday resort, but is int to assist poor educated women to get back to the earning ranks after illness. The following cas inadmissible: neurasthenia, infectious cases, c cases, cases requiring special dietary, surgical dressi those suffering from any illness of an objectionable Patients must be capable of dressing themselves, of about without help, and of attending meals in the room. Full particulars may be obtained from the m Miss N. S. Townshend, A.R.R.C., the Manor House Malling, Kent.

Arris and Gale Lecture*

ON THE

PHYSIOLOGY OF VIOLENT EXERCISE

IN RELATION TO THE

POSSIBILITY OF STRAIN.

BY ADOLPHE ABRAHAMS, M.D. CAMB.,
PHYSICIAN TO OUT-PATIENTS, WESTMINSTER HOSPITAL;
PHYSICIAN TO THE HAMPSTEAD GENERAL HOSPITAL.

THE capacity of a human being to undertake feats of exertion and of endurance makes an appeal to different classes from varying angles. On the mechanical side there are anatomical and dynamical problems of absorbing interest. To the physiologist the subject is one of infinite possibilities for research, whether on the lines of neurology, of cardio-respiration, or the more subtle mysteries of biochemistry. To the clinician, inclined naturally to view the body less as a complexity of systems than as a medium for pathological opportunities, there is ever before him the possibility of strain or over-stress; and a solicitude, in the exercise of his profession, to utilise his authority in the prohibition of such activities as are likely to produce temporary or permanent injury. The average non-technical man is eager to dwell upon the remarkable capabilities of his body without any particular interest in the scientific principles comprised. He sees a machine which can propel itself unaided over the ground at the rate of nearly 25 miles an hour; which, represented by a Marathon runner, can progress for nearly three hours at the rate of ten miles an hour independently of fuel save that supplied by its own tissues and exhibiting no greater sign of injury than a few blisters on the feet—scratching off the paint of the machine; which, represented by a Channel swimmer, finds cold, hunger, and fatigue almost equally indifferent in comparison with the boredom of monotony. He sees a machine which is capable of feats of endurance not so exactly definable but more remarkable when exemplified by Arctic explorers, besieged garrisons, shipwrecked mariners, and the like. His interest in physiological research into his doings is strictly utilitarian. Can the physiologist discover something which will enable him to knock off a vital fifth of a second from his time on the track? Occasionally the physiologist thinks he can, as in the presidential address to the Physiological Section of the British Association in 1925, when Prof. A. V. Hill, in "The Physiological Basis of Athletic Records," was equally happy in his title and its interpretation.

It will be my task in this lecture to try to examine the subject inductively as a student of elementary physiology, and deductively as a student of clinical medicine. In any such inquiry—and this is by no means the first of its kind—it is generally evident that one or other qualification in the inquirer has dominated. An enthusiastic athlete may be reluctant to admit the existence of any fault or danger in a favourite exercise which the physician, unduly impressed perhaps by his acquaintance with disease, is too prone to expect or recognise. It may be a handicap sometimes to have more qualifications than one for judging a given subject.

In an appeal to authorities the conscientious inquirer into the effects of violent exercise is bewildered by discrepancies and contradictions. He learns from one source that exercise causes dilatation of the heart, from another that the heart is actually smaller after exercise than before. He is prepared for the information that the temperature of the body rises as the result of exertion, and yet he is alternatively informed that researches upon Marathon runners have shown that their temperatures were subnormal. No less an authority than Osler says that the blood pressure is greatly increased; a series of accurate observations by modern apparatus proves that it is lowered. The pathology of violent exercise is certified by the occurrence of albuminuria; physicians with special experience say that this is a negligible physiological circumstance. Such contradictions may well induce despair and impatience, until it is made clear that both sides are right, if only all the facts and circumstances are known.

I have no intention of demarcating the scope of my subject and defining where moderate exercise leaves off and violent exercise begins. An easy feat of exertion for one person may be reasonably regarded as moderate for another, and even described as violent for a third. I shall in general be dealing with exercise which approaches the limit of human possibility, and it is a necessary if arbitrary assumption that the human material in question is perfectly healthy.

THE CONSUMPTION OF OXYGEN.

Although oxygen is essential for the vitality of mammalian muscle, muscular contraction is anaerobic. It is pertinent to contrast the work of a muscle with that of a combustion engine. In the latter, oxidation precedes work; in a muscle, work precedes oxidation. The muscle may be regarded as a storage battery working on energy previously stored; and when exercise is over that energy has to be restored by the consumption of oxygen. The anaerobic contraction breaks down sugar into lactic acid, which has during the recovery process to be oxidised into carbon dioxide or converted into sugar and glycogen. The amount of oxygen consumed in the recovery process is a criterion of the degree of activity of the muscle; it is directly proportionate to the accumulated lactic acid. During rest the intake of oxygen is about 250 c.cm. per minute; during the most violent exercise a maximum of about 4 litres per minute may be consumed. In one isolated experiment an extreme consumption of 4·4 litres was observed. If the exercise taken is of such severity that the lactic acid produced by the muscles is no more than can be removed simultaneously by the influence of oxidation at the rate of 4 litres of oxygen per minute, fatigue will not occur until other factors of exhaustion enter into the problem. But when really violent exercise is taken the generation of lactic acid is enormously increased. For example, in the case of a sprinter running 100 yards in ten seconds, 40 g. of lactic acid accumulate in ten seconds, 1 g. for every stride taken, and this will require 6·7 litres for oxidation. The maximum oxygen intake during ten seconds is less than a litre, and most sprinters do not breathe at all throughout a 100 yards race, since immobilisation of the thorax is an aid to locomotion.

The 6·7 litres subsequently used for oxidation is what Prof. A. V. Hill aptly calls the "oxygen debt." When more prolonged exercise is taken, the oxygen used during respiration may, in this phraseology, be regarded as income; the oxygen debt run up is borrowed on the security of the lactic acid. So long as the security remains adequate, by so much may the expenditure of oxygen exceed income. The absolute limit, the largest oxygen debt possible in the case of the finest trained athlete, is 20 litres, corresponding to about 120 g. of lactic acid, which is an enormous saturation for a muscle to endure.

From these considerations it is fairly obvious that the natural capacity for athleticism depends upon a number of factors. A man may fail to be a good runner because his oxygen intake is small, or because his oxygen requirement is high, or because his credit as regards incurring an oxygen debt is poor. His oxygen requirement may be extravagant because his movements are wasteful, a fault which training may eradicate or reduce. It has even been shown by A. V. Hill that the impairment of movement occasioned by a blister on the foot causes a considerable increase in the oxygen requirement. His security as regards oxygen debt is partly constitutional and partly the result of training, for it depends on the capacity

* Delivered at the Royal College of Surgeons of England on Feb. 13th, 1928.

of the muscle to neutralise fatigue products or to tolerate their presence, and also upon the willingness of the individual to push himself to the degree of exhaustion. The subject of oxygen intake is not without its complexity, for it includes the factor of coefficient of utilisation, a problematical increased ability of certain muscles to take up oxygen from the blood. The essential feature, however, is the "minute volume" of the heart—i.e., the amount of blood circulating per minute. For an athlete to ensure the maximum oxygen intake of 4 litres per minute, a blood flow of 37·6 litres, or approximately 8 gallons, per minute is required. To produce this enormous volume two factors are involved—output per beat and frequency of the cardiac rate.

Cardiac Frequency.

At the beginning of exercise and, in fact, in anticipation of it, especially if there are emotional accompaniments, a simultaneous tuning-up of parts of the nervous system as a psychical process leads to increased frequency and depth of breathing, increased cardiac rate, and increased blood-supply to the body as a whole and particularly to the muscles and the brain. Acceleration of the heart at the beginning of exercise is mainly due to loss of vagal tone, and partly to an increase in accelerator tone. Loss of vagal tone is characteristic of shortening of diastole; stimulation of the accelerators influences systole as well as diastole. These initial changes provide increased oxygen before other mechanisms come into action. Continuance of increased cardiac frequency is in part determined by a continuance of impulses from the higher centres to the medullary centres, in part by the increase of adrenalin in the blood stream, in part by rise of temperature, and in part by increased venous pressure. The last was shown by Bainbridge to be the most important of all. Any rise of pressure in the auricles, or accumulation of blood in the great veins, leads to diastolic distension which reflexly decreases the tone of the vagus centre.

In the meantime, respiratory movements play their part in contributing to circulatory efficiency. The increased capacity of the thorax opens up the thin-walled veins, so that blood is aspirated towards them from the extrathoracic venous system and passes more readily from the right to the left heart. During expiration, compression of the veins expels blood into the left ventricle and so into the arteries. The respiratory movements clearly accelerate the blood flow and raise the arterial pressure. That there must be a considerable difference in the contractile power of the cardiac fibres, with a corresponding difference in the output per beat, is indicated by the observation that the maximum cardiac rate during exercise is much the same whatever the capacity for exertion. This maximum is generally accepted as 168 beats per minute, though I have noted a rate of 192 on a few occasions. With moderate exercise the comparatively untrained person can accelerate sufficiently to compensate for a relatively poor output per beat, but this adjustment is limited and distress is inevitable in extreme exertion. It is frequently forgotten that the rapid contractions of a vast number of muscles have an important accessory pumping action in pressing blood onward by the valves of the veins, an action which in Bainbridge's opinion may be equal to, or transcend in, importance that of the heart itself. This affords an explanation of the severity of rowing compared with running. In the former the movements of the body are not rapid enough to give this assistance to the heart.

Blood-supply of the Heart.

Exertion entails a large increase in consumption of oxygen by the heart's own muscle. It has been calculated that at least 125 c.cm. per minute may be consumed—half that required by the whole body at rest—so that the blood-supply to the heart must be one of the decisive factors which determine capacity for muscular work. Skeletal muscle can tolerate a considerable quantity of lactic acid in the absence of adequate oxygen, but this privilege of "runni into debt" would clearly be highly dangerous the heart, which must be protected against exhausti itself beyond recovery. Hence the heart's output once diminishes when its oxygen-supply becon inadequate, and it will be readily understood that coronary blood-supply of the highest efficiency imperative.

Dilatation of the Heart.

Much misconception exists on the nature of dila tion of the heart, and the ill-effects of violent exerc which it is supposed to reflect. Dilatation is a phys logical process; it is an essential part of t mechanism by which the heart can increase or ma tain its output. Starling's law of the heart postula that the energy of contraction by which all mus substance is always measured is a function of t length of the muscle-fibre. The greater the volu of the heart, within physiological limits, the grea the energy with which it contracts. The heart, th dilates in order to increase its output in direct respo to a larger venous inflow. Dilatation increases c tractile power and so output per beat, and a co paratively slight dilatation enables the heart empty itself completely at each beat. Yet, althou the law of the heart is a constant, the actual contract power of the heart must vary with the character the fibre itself. A heart with musculature of super contractility need not dilate under stress in attempt to increase its contractile power to t same extent as one with inferior muscle. A thi walled, compact heart with an increased number fibres (to say nothing of a hypothetical superior of material) must constitute a more efficient pu than a less well-developed heart. It is the failure correlate these views with clinical observations wh has led to discrepancies, contradictions, and entir erroneous statements.

Size and Efficiency of the Heart.

The size of the heart is not so absolute as so observers would have one to suppose. It bears relation to the age, stature, and build, and an ap rently large heart may be normally commensur with the general musculature of a well-develo man. Furthermore, the influence of such factors alcoholism, in men accustomed to certain forms exertion, has to be discounted. Secondly, the meth of estimating size by percussion involves the perso factor too largely for absolute accuracy to be possib and even in radiology the personal factor is not be ignored, to say nothing of technical difficulti That some dilatation of the heart occurs dur exercise is certain; as we have seen, it is phys logical. But to assert that permanent enlargeme whether pathological or not, occurs is anot matter. Physiological dilatation disappears imm diately upon the cessation of exercise, a fact which depends the chief value of radioscopy in t investigation, and one which demonstrates t unreliability of evidence derived from percussi To obtain the absolute size of the heart, tele-rad graphy under the best conditions is almost if quite indispensable. Even so it is desirable to ins tute special refinements to be sure that, although increase in the horizontal direction is observab any antero-posterior increase may be detected. all the athletes I have examined with the skill coöperation of Dr. H. Courtney Gage, not one h exhibited any suggestion of a heart larger than th proportionate to his height and build. In fact, t surprising feature is the impression that the heart of less than average size. This supports the hypothe that there is a variability in the quality of cardi tissue, and unquestionably disposes of the long-he fallacy that violent exercise leads to permane cardiac dilatation.

I have stated that there is very little difference the cardiac frequency upon exertion between athletic and a non-athletic heart. Some differen however, may be noted in their deceleration cessation of exercise, and this is of some interest

uggesting a means of estimating cardiac efficiency. ts limitations are obvious; an untrained man annot be subjected to prolonged exertion and, for easons which I shall give later, I doubt if the usual xercise tests in the laboratory have much value. regret that it has been impracticable to arrange to arry out on distinguished athletes the prolonged and umerous investigations which are necessary; isolated bservations, especially on competitive occasions, are itiated by psychical disturbances. With this apology will now refer briefly to the results of personal experiients, conducted over a period of 14 years, and epresenting the averages of a very great number of bservations.

A man accustomed to running can acquire a erfect automaticity of action, and so a fixed speed. hus, I myself discovered that I could run for ten iles at a fixed rate of 6 minutes, 32 seconds per mile. dopting this as a constant velocity, variations of he distance run gave a convenient estimate of the ork performed. Such a proceeding has naturally an dvantage over any mechanical exercise, such as nning up and down stairs, stepping on and off a air, lifting dumb-bells and so on, the circumstances nd monotony of which prohibit prolonged research. ow, as one would expect, the maximum cardiac equency, whatever the distance run, is not very ariable. After 100 yards the heart is beating at 168; e resting rate is reached in a minute and a half fter cessation. After 220 yards, the normal is ached in 2¼ minutes; after a quarter of a mile, 20 minutes; after 5 miles not for 4½ hours, and fter 10 miles as long as 6–9 hours may elapse. lthough persistence of tachycardia is to some xtent proportionate to the duration of the exertion, e conspicuous feature is that the initial deceleration in all cases exceedingly rapid, and that the bulk the time taken is occupied by the slow final stage fter a relatively slow rate of frequency has been ached. Thus, even after ten miles, the rate had llen from 192 to 120 in two minutes. Duration of xercise plays a larger part in prolonging the freuency than intensity of effort, for to run a furlong full speed is, subjectively considered, as exhaustg as five or even ten miles at the slow fixed rate. et the resting stage after the fast furlong is reached 17 minutes. Persistence of cardiac frequency ould appear to be due to inhibition of vagal tone, d is associated with increased metabolism.

Effort Syndrome.

It may be pertinent to consider whether the phenoena of prolonged cardiac frequency can be brought to line with those noted during the war in the -called "soldier's heart," a term naturally intended draw attention to factors inseparable from military e, and to suggest a sort of occupation disease. hese symptoms are, however, familiar enough civil life, and they were suitably included by r Thomas Lewis and those working under s direction in the general term "effort syndrome," describing the condition of an individual nstitutionally ill-adapted to exertion. The ore active circumstances of military life do t create the condition, but simply unmask it. he subject of effort syndrome has a greatly reduced pacity for exertion, and his inefficiency is demonated by the extent to which deceleration is proged, even after trivial exercise within the subject's f-accepted limit—e.g., doubling 100 yards slowly—en as long a time as 9½ minutes is required before e resting rate is reached. Hyperpnœa and vasotor instability are also very evident, and I am able to agree that any definite evidence exists that e heart itself is the chief factor to be considered.

It is difficult to separate a constitutional defect m a disability amenable to treatment. I have n from personal experience how half a dozen lled investigators with a bias towards different ological possibilities unconsciously divert the estionaire of a patient with effort syndrome wards the particular cause they favour, whether it be psychic, toxic, rheumatic, endocrine, or exertion. If, as I believe, the condition is constitutional, it is again difficult to incriminate any one system. The subject may possess ill-developed coronary vessels, poor contractile power, or defective muscle-fibres. The inefficient athlete convicted of a yellow streak may be unfairly condemned; the yellow streaks may be in his heart muscle. Or an over-active cortex cerebri may fail to protect the heart from uneconomical over-activity. Or the fault may be biochemical, a disturbance of the normal relationship between the production of acid in the muscles and excitability of the respiratory centre. There may even be a more general disturbance of metabolism, and the equilibrium between the reaction of the red cells and that of the plasma may be upset. In diminished alkalinity of the blood less carbon dioxide is needed to excite the respiratory centre, so that hyperpnœa is easily produced.

I should be more convinced that shell shock and gassing might produce this condition had I been personally acquainted with men who, although previously possessing a good exercise tolerance, had exhibited effort syndrome after their ordeal. The sensation of being gassed, which I know from personal experience to be terrifying, may well disturb a hypersensitive medulla; similarly, trench fever may, according to one's predilections, be regarded as acting upon the myocardium or the vaso-motor centre. The cardiac muscle is, upon the authority of eminent cardiologists, very susceptible to bacteria and other toxins. Nevertheless, I doubt whether the temporary depression of activities in toxæmia is an indication that the heart is affected. I have always regarded the subjective sensations, asthenia, excessive perspiration, and so on as of vaso-motor origin. Were the heart directly affected, would not the influence of exercise upon the cardiac rate and recovery be manifest? On two occasions, when suffering from a toxæmia with pyrexia of 102°, I ran four miles; once with the hope that the infection might be aborted, once deliberately to see what would happen. The sense of exhaustion was considerable, but neither the cardiac rate at the termination of the exercise nor the prolongation of tachycardia varied in the slightest from observations made when the same exercise was taken under ordinary conditions of well-being. Graduated exercises produce improvement in some cases of effort syndrome, yet this does not appear to me a proof of training of the heart as such. The improvement which takes place may be a result of better coördination of the centres involved. I cannot regard the exercise tolerance test as any indication of the efficiency of the heart. It certainly has a distinct bearing upon capacity for exercise, but that is bound up with many other factors.

RESPIRATION IN EXERCISE AND SECOND WIND.

At the beginning of exercise, and frequently in anticipation, the respiratory centre, in common with the other medullary centres, is psychically stimulated, so that the frequency and depth of breathing are increased. During exertion, both oxygen deficiency and increase in the hydrogen-ion concentration of the blood increase the activity of the respiratory centre; the oxygen deficiency increases the sensitivity of the centre to its specific stimulus, the hydrogen-ion concentration. Probably carbonic acid is a stimulant independently of its acid property when in solution. Rise in temperature, which may occur and which, in fact, must occur if the exercise is sufficiently intense and prolonged, also increases the responsiveness of the centre. The respiratory centre is called upon to ensure maximum ventilation of the lungs and to regulate the reaction of the blood.

A comparatively trivial change in the reaction of the blood may bring about a large increase in pulmonary ventilation, and it is suggested that this circumstance provides an explanation of the phenomenon "second wind." At a more or less fixed period in the course of exercise the sensation of acute breathlessness passes off, yet more rapid breathing is evident.

Nor is the change restricted to the respiratory side; in a well-marked case it seems as if a new supply of energy had been tapped. Pembrey and Cook concluded that the cause was cardiac, as a less frequent and more regular contraction of the heart occurs after the advent of second wind. Considered chemically, however, the characteristics of second wind are a fall in the alveolar tension of carbon dioxide and a decrease in pulmonary ventilation due to diminished hydrogen-ion concentration of the blood. This diminution can only mean a lowered production of acid in the active muscles or a more rapid oxidation, and this must imply a more perfect adjustment of all the coördinating factors which are essential for efficient violent exertion. By the time the athlete has got fairly into his stride, and all systems are working at their highest efficiency, second wind may be said to be established.

It will be understood why the phenomenon may be almost abrupt in one man and so gradual as to be imperceptible in another, according to the method of adjustment. It is because of the dramatic change in the first type that the term has arisen, but in the perfectly trained athlete it might be said that the "first wind" is never lost until general fatigue sets in. It is exceedingly difficult to count one's own respirations, for such attention is inimical to accurate observation. But so far as I have been able to ascertain during the course of a run, the respirations increase gradually to 30 per minute and then rapidly to about 54. Despite the polypnœa there is no sense of distress, but it is of course impossible to estimate the depth of the respirations.

Influence of Emotion.

The association of emotion with activity of the visceral sympathetic system is well known. Stimulation of the medullary centres concomitantly with stimulation of the muscles causes an increase in pulmonary ventilation, accelerates the cardiac rate and contractile force, and dilates the coronary vessels. This massive activity is bound up with increase of adrenalin, which, in addition to its so-called sympathetic action, stimulates the liver to turn out glycogen and so increase the available supply of circulating sugar. Glycosuria occurs during athletic activity, especially in connexion with emotional strain, and hypoglycæmia from adrenal exhaustion is seen in very prolonged feats of exertion. Contemplation of increased adrenal activity prepares us to understand how an emotional stimulus can call forth an unexpectedly great effort apparently beyond the athlete's powers, for instance the supreme final spurt of a man on the verge of collapse.

Blood Pressure.

Among the discrepant statements on the effect of exercise is that relating to blood pressure, and again the contradictions are explained when the circumstances of investigation are appreciated. It is interesting to refer to what is, perhaps, the earliest observation upon the subject. Dr. Mahomet, then pathologist to St. Mary's Hospital, stated after his investigations of Weston, the long-distance walker, that exercise might reduce or raise arterial tension. Reduction occurred, he said, if the subject was out of condition, and might produce syncope from cerebral anæmia. On the other hand, he explained a rise of arterial tension as due to irritation of the vasomotor nerves by an exhausted brain, and hence to contraction of the arterioles, or, alternatively, as due to capillary obstruction from impaired nutrition of tissues.

To determine the influence of exercise upon the blood pressure it is essential to make observations during the exercise, when it is found, as one would expect, that a rise is invariable. If observation is delayed until the termination of exercise, even if only a few seconds have elapsed, a fall below the resting rate will be detected. It is easy to see, therefore, how diametrically opposed statements have been made. The rise in blood pressure may be considerable without much concomitant increase in cardiac rate, as in lifting a heavy weight. A high arterial pressure is absolutely necessary for the efficient performance of muscular work. The rise is provision for ensuring a maximum supply of oxygen, as during exercise the flow of blood through the muscles may be six or eight times greater than at rest. Furthermore, the coronary blood flow depends essentially upon arterial pressure. The systolic rise is much greater than the diastolic rise, and an increase during exercise of 80 mm. is by no means unusual.

Increased arterial pressure is due not only to increased output of the heart, but also to constriction of the splanchnics and dilatation of the peripheral vessels. Splanchnic constriction is due to impulses which, arising in many ways, psychical and chemical influence the vaso-motor centre, whilst arterial tone is lessened by metabolic products.

Immediately at the end of exercise the muscles relax instantaneously, the depleted veins of the abdomen and limbs take up the blood flowing from the capillaries, the heart is momentarily robbed of its supply and there is a steep fall in arterial pressure. This fall may be responsible for a temporary giddiness and faintness, and so naturally susceptible to gloomy misinterpretation. The pressure remains reduced until the veins fill; this overflow feeds the heart, so raising the arterial pressure, which gradually falls to the pre-exercise level and often a little below it within three or four minutes. This is, of course, in striking contrast to the delayed reduction of the increased cardiac rate.

The athlete's resting blood pressure is distinctly low. Hence, whilst his arterial system is subjected to very considerable pressure for the limited period of exercise, there is compensatory reduction during his resting life. There appears to be no foundation for the statement that arterio-sclerosis—i.e., a degenerative change—occurs in the vessels as the result of much violent exercise. Certainly, so far as blood pressure estimations are valid, no evidence is forthcoming. When strain has been regarded as the determining factor of arterial changes, the part played by syphilis, alcohol, tobacco, and other toxins as well as the natural quality of the arterial wall, has to be assessed. To see whether 27 years of exercise would show an effect upon the arterial system, a portion of my left radial artery was excised. The section has been submitted to Prof. Sir Edward Sharpey-Schafer, who reports that the details are indistinguishable from those of a radial artery of a healthy young man who has taken very little exercise.

Professors and directors of physical education in the American colleges are often prepared to judge the fitness of an athlete by his response to posture as indicated by alteration in his blood pressure and cardiac rate. When a very fit man rises from the horizontal position, acceleration of the cardiac rate should be trivial, a small rise of blood pressure is usual, and these two results may be correlated into a factor of physical efficiency. An increase of cardiac rate of less than four beats per minute and a rise of blood pressure of 10 mm. would be graded 100 per cent. A man with very poor vasomotor tone, either constitutional or after illness, will often show a fall in blood pressure and a considerable rise in cardiac frequency. My own investigations do not lead me to place any reliance on the test as an index of athletic efficiency, since there are many discrepancies. Above all, emotional factors produce most violent disturbances, vitiating any attempt at systematic investigation.

The Temperature in Exercise.

The efficiency of the body as a machine has been estimated by Benedict and Cathcart at 20 per cent. in an average untrained subject and 33 per cent. in one fully trained. A great deal of heat is inevitably produced which cannot be converted into mechanical work. To a certain extent heat ensures maximum

fficiency. A rise in temperature increases the excitability of the nervous system and especially, as I have entioned, of the respiratory centre; it causes the cretion of more fluid from the synovial membrane nd so smoother working of joints. In homely nguage, the engine does not work at its best until is warmed up. Perhaps the most important consquence of raised temperature is the increase in the hole chain of chemical action involved in muscle etabolism. The velocity with which human hæmobin parts with its oxygen increases about fivefold r a rise of temperature of 10° C., the velocity with hich it acquires oxygen being unaltered. During distance race a rise of temperature of 7° F.—i.e., ' C.—is not exceptional, so that the velocity ith which oxyhæmoglobin can break down is ubled. One observer has stated that the temperare of Marathon runners actually falls, but his records ere based upon mouth determinations which are alueless. Rectal temperatures show that a rise variably accompanies exercise, the extent depend- g upon the external temperature, the humidity of e atmosphere, and, of course, the severity of the ercise. I have reason to believe that a subantial psychical rise may occur when there is mpetition.

A large number of personal observations show that e rectal temperature after a run of about nine miles generally between 102° and 103° F. The highest mperature I ever noted was 105·8°, on a day when nditions were particularly unfavourable to heat loss. ie temperature rapidly falls and reaches normal thin two hours. There is clearly danger of hyperrexia in prolonged efforts under unfavourable nditions. It is the practice for the classical Marathon ce to be run in one of the summer months and nerally during the hottest hours of the day, a actice against which I have more than once warned e authorities. At the Olympic Games at Stockholm 1912 a Portuguese competitor collapsed on the road d died of alleged sunstroke, which was probably at-stroke. During the games at Paris in 1924, the ,000 metres cross-country race was run on an sufferably hot, humid day without a breath of nd. Nearly all of the few competitors who finished re in a condition not only of collapse but also mental distress and disorientation. When the rathon race was held a few days later, there was tunately a fall in the temperature with a cooling eze, or fatalities might well have occurred.

Comparatively simple experiments show that there no foundation for the idea that the pyrexia of exere determines the persistent cardiac rate. Elaborate d thoroughly conclusive experiments will be found an article by Martin and others in the *American urnal of Physiology*, 1914, xxxv., 211.

Changes in Blood and Urine.

During exercise on the level or at comparatively v altitudes increase in both red and white cells curs, but above 2000 feet the increase is restricted the leucocytes. Exercise causes the passage into e blood of a number of reserve red cells which lie rmant, and which, in consequence of splanchnic nstriction by adrenalin, are dispersed to the periery and so ensure a maximum supply of oxygen the muscles. But at altitudes no such dispersal occur; the perpetual demand for a maximum tribution of red cells to the periphery permits of reserve. Leucocytes, however, increase in the ipheral blood at altitudes equally as on the level, ause exercise squeezes lymph out of the muscles l drives it to the heart, and with it are carried the ocytes gathered from the tissues. The altered ribution of the red cells, at first determined by nchnic constriction, is continued when perspiration s in, for this produces increased density of the od and so increased oxygen-carrying capacity for t volume. The advantage of free perspiration thus uires an additional significance, apart from the idance of over-heating and the lowering of perial resistance.

Apart from the question of albuminuria, which has acquired a special importance, the investigation of nitrogen metabolism in exercise has received little attention from modern workers. The feats of Weston, the long-distance walker, in the year 1870 supplied an opportunity to contemporary physiologists, who exhaustively analysed his diet and excreta for many weeks. In this connexion must be mentioned such classic names as Austin Flint in America and Pavy in this country. The conclusion ultimately derived—that non-nitrogenous food is the source of muscular energy—is now of historical interest, since observation of the respiratory quotient shows that the energy expended by muscles must ultimately be derived from fat and carbohydrate, with a preferential utilisation of the latter.

There is, as Ryffel has shown, an increase of lactic acid in the urine after exercise. There is also an increase in phosphoric acid, which apparently plays some special rôle in the breakdown and restoration of glycogen in muscle, and it has been stated, though I have been unable to confirm this, that the muscular output of a trained man is considerably increased by an ingestion of phosphates. The Germans administered phosphate of sodium in large doses to their "storm troops."

I have frequently found an increase in oxalates after an intense effort, though whether the metabolic activity is of nervous or intestinal origin I am unable to say.

There is sometimes a transient (physiological) glycosuria after exercise. The enormous increase in adrenalin in the circulation explains a temporary hyperglycæmia with glycosuria; the subsequent adrenal exhaustion, which may occur in protracted efforts, would be responsible for the hypoglycæmia which has been described in Marathon runners. When the existence of hypoglycæmia was first demonstrated by insulin, I ventured to speculate that the symptoms of distress from exertion might find their explanation in hypoglycæmia. Levine and his fellow-workers in America have shown that hypoglycæmia occurred in Marathon runners who exhibited exhaustion, which is usual between the fourteenth and eighteenth miles. They correlated the degree of distress with reduction in blood-sugar, and in subsequent observations upon the same runners they prevented distress by the administration of sugar before and during the race. Although it is unlikely that hypoglycæmia can be directly responsible for fatigue, save in very prolonged feats of exertion, nevertheless the part played by carbohydrates encourages their ingestion at a suitable period before the effort. It is interesting that the modern conception of carbohydrate metabolism has endorsed this long-standing empirical practice of athletes.

Deaths from Exertion.

Excluding hyperpyrexia, it is significant that the majority of sudden deaths associated with some feat of exertion are on the golf links, and their subjects elderly and plethoric with degenerate arteries. In the rare instances when a young and presumably healthy athlete has succumbed, there has been too ready a tendency to assume the influence of exertion, and post-mortem inquiry has rarely been undertaken. Last summer a verdict of heart strain was returned in the case of a young man who fell fainting from an eight at Henley and was found dead on removal from the water. I made all possible inquiries, and the doctor who had been called was kind enough to send me the fullest details. There had been, in fact, no antecedent exertion, as the boat had only just left the landing-stage. No autopsy had been performed, but from the doctor's description of the body it seems almost certain that status lymphaticus was responsible.

Prejudice must inevitably play a part in deciding whether or not any permanent alteration in the heart can result from one extreme feat of exertion or from a long-continued athletic career. Some observers regard any circulatory disability as being

attributable to exercise, and do not realise that exercise has revealed a latent organic defect in a heart hitherto regarded as sound. In an article in 1870 the medical officer to Rugby School, deprecating running on account of the strain thrown on the circulation, noted that "the recent death of England's greatest sprinter from aortic aneurysm is significant." So it is, but not exactly in the way he meant!

Sir Clifford Allbutt suggested the term "overstress" in preference to "overstrain," since any strain is overstrain. The behaviour of a healthy heart under great stress bears no resemblance to cardiac failure—dilatation, cyanosis, venous engorgement, enlarged liver, œdema—so that failure of ventricular muscle cannot be responsible. I have already indicated the fallacies relating to recognition and estimation of enlargement of the heart; auscultatory peculiarities, sometimes demonstrated, often occur under normal conditions. When one recalls the symptoms described by nervous people with perfectly healthy hearts one realises that subjective sensations are valueless. Such factors as chronic infections, dyspepsia, insufficient sleep, and puberty with its inherent nervous instability, are likely to be overlooked in adolescents and ill-effects from violent exercise are too often assumed. This is not to say that overstress leading to permanent strain is impossible, though the exact method of its production may be problematical and its detection may be beyond our capacity. There may be an alteration in the molecular state of the fibres of the cardiac muscle, some subtle change resulting in lessened contractile power. This is all hypothetical. There is no evidence that any such effect ever occurs, and I prefer to visualise overstress, and perhaps strain, if it occurs, as a far more general condition. A healthy and powerful heart is a sine quâ non to a would-be athlete, but the feature which distinguishes the athletic man from the non-athletic is the equilibration of all the factors concerned—heart, lungs, muscles, and skin, as well as his biochemical machinery. If overstress really occurs it lies in a general disturbance of this fine equilibrium. Sir James Mackenzie had "personally never seen such a thing as a strained heart." Sir Thomas Lewis expresses the same view. He says that the circulatory organs are built to stand the strains which they themselves create; their reserve is often underestimated. When the call is excessive, it is the full supply of blood to the muscles which will fail and not the heart. Dr. G. A. Sutherland points out that certain alleged cases of strain are really organically damaged hearts, unrecognised until the breakdown, whilst others are instances of natural peculiarities mistaken for pathological conditions. Cabot, in a classification of groups of heart disease, remarks that, had any of them occurred in athletes or ex-athletes, they would have been called athlete's heart.

Exercise and the Lungs.

Very little attention has been paid to the possible deleterious influence of exercise upon the lungs. From time to time the death from pneumonia of a young man with an outstanding aquatic record has stimulated the gloomy forebodings of those who are convinced that even one severely contested boat race may lead to pulmonary weakness and greater susceptibility to infection. From time to time the development of pulmonary tuberculosis in a brilliant young athlete affords sufficient proof to those disposed to deprecate violent exercise. I venture to put forward the possibility of a direct relationship between the tuberculous diathesis and athletic ability, although it is very difficult, if not impossible, to prove that the tuberculo-toxin may confer a flair for athletics. In my own experience, two famous middle-distance runners have phthisis, and a third was compelled to leave this country to reside in South Africa a year after terminating an exceptional athletic career. That violent exertion contributes to the progress of a lesion is a reasonable charge, although it is at least arguable that the exercise may operate in the opposite direction. The instances of pneumonia are too isolated to exclude coincidence. On such a line of reasoni exercise might be held responsible for any concomita occurrence, good or bad. The oarsman is usually ta and tall men are less resistant to diseases of the lur than men of more compact build. The after-histor of men who rowed in the boat race show that t participants have a better life expectation than t average. Morgan's book, "University Oars," w published in 1873 as a counter-claim to Skey's lett to the *Times* in 1867. Morgan undertook an exha tive inquiry into the past and present health of t men who had rowed in the 40 preceding boat rac Meylan studied the after-histories of the Harva oarsmen who rowed from 1852 to 1892. Both his a Morgan's figures showed an increased life expectati of five years over the insured group, which is a select risk. Such figures are convincing, but the mate investigated is exceptional, and it may be contend that their life expectation might have been ev longer if they had not rowed. They serve at le to show that there is no indication of an adve effect. Dr. Bradford Hall has recently publish statistics of the longevity of cricketers.

Organs of Digestion and Kidneys.

The influence of exercise upon the organs of dig tion is to a considerable extent beneficial. T general stimulation of metabolism, the increa elimination of waste products, not to mention habitual psychic associations, are, as a rule, favo able to appetite and digestion. Yet digestive turbances among the athletic are far from infreque Indigestion is one cause of "stitch," but this i disability with many possibilities. There is this day some survival of traditional absurdi about diet in training. Such a cause for dyspep can, of course, be avoided, as can the disadv tage, not to say the danger, of undertak violent exercise soon after a heavy meal. If fairly widespread belief that appendicitis and d denal ulcer are relatively more frequent in athl young men is true, it is not difficult to predic plausible reasons. The powerful contractions abdominal muscles thrust the viscera down into pelvis, and from mechanical difficulties the ile becomes unnaturally full and sags. Traction on duodeno-jejunal junction causes duodenal distens and, subsequently, yielding in the first (relativ mobile) part, with a tendency to give way on convex surface—the commonest situation for ulcer.

The tendency for violent exercise to prod albuminuria has naturally been regarded as a ser disadvantage and an indication to prohibit exer to predisposed persons. In his contribution to *Transactions* of the Medical Society of Lon (vol. xxx., p. 18) Dr. Collier, of Oxford, expressed opinion that albuminuria should no longer be regar as a cause for pessimism and a reason for limi the subject's activities. Was it not, he asked vascular occurrence in a comparatively labile syst To do full justice to Dr. Collier's contribution should remember that the bare occurrence of a minuria had previously been regarded as evidenc renal disease. I have been struck by the compar of my own observations with those of Dr. Co and Dr. Lemprière and others with excepti opportunities for investigating athletes. Dr. Co invariably found albuminuria in oarsmen after a r row; Dr. Lemprière found it in schoolboys even comparatively short runs. Working, as I h among seasoned track athletes undertaking the extreme exertions, I have seldom found abno urinary constituents. I believe that in rowing mechanical side of the exercise conduces to co tion and pressure upon the prostate and culæ seminales, with the subsequent appear of their secretions in the urine. Moreover, the and relatively labile vasomotor system of n oarsmen and all schoolboys bring their post-exe albuminuria into line with postural and cy albuminuria. I have in several instances found

he albumin was precipitated by dilute acetic acid n the cold.

After very violent exercise a few casts are generally ound, but as they are transitory any renal alteration nust be trivial. Nothing short of a vigorous 5 mile run roduces casts in my own urine, and none is present ix hours after the effort. A professional pedestrian, ged 51, after a successful attempt upon the world's ecord for an hour's walk, passed granular casts for 2 hours only. An Olympic champion, aged 23½, after unning half a mile inside world's record time, passed rine which contained only the faintest trace of lbumin and no casts. I select these as two athletic eats of exceptional severity; it is clear that renal hanges due to the most violent exercise are ephemeral nly.

The Nervous System.

I have more than once indicated that the 'seventies vere particularly intrigued by the evils of athletics, he serious possibilities of which extended even to nsanity. In a medical journal of 1870 I have iscovered a long account of the influence of xercise upon a university oar, who, trying to ombine his athletic career with an attempt to vertake academic arrears, became mentally eranged. I cull the following from a paper in 876: "If any psychologist will take the trouble o trace out the history of each of our eminent edestrians, he will discover that a very large roportion of them have been subject to some ort of madness." At the present day the worst 'e can say about the nervous side of the athlete is nat he is neurotic, and we do not necessarily maintain nat his neurosis is the effect of exertion; but rather nat it is the outcome of competition, anxiety, public dulation, and the like. The athlete preparing for really important contest thinks of little else roughout the whole of his waking hours. The rain imposed upon prominent lawn tennis players ngaged in competition for the greater part of the ear may well lead to a nervous condition which is nly indirectly related to the physical exertion. The ontinuous overflow of nervous impulses to the nuscles, the complex processes involved in coördinat- ig skilled movements and in focusing attention, ogether with such mental factors as excitement, pprehension, anxiety, and judgment, must involve considerable expenditure of nervous energy during ompetitive physical exercise. This applies with reater force to young women and girls participating n tournament play and track athletics. Their nore delicately organised nervous system and greater isposition to psychical disturbances, not to mention ne diversion of energy from channels for which it is pecially required, are factors conducive to over- ress. Excluding feats of endurance, for which a elative phlegmatism and stolidity are desirable, the thletic temperament approximates to what is opularly termed the "highly strung," and the thlete is generally "vago-tonic."

The literature of physical exercise in its physio- ogical and pathological aspects is a great deal more oluminous than is generally recognised. For many nportant contributions we are indebted to American hysicians, who enjoy special opportunities for esearch upon the athletes in their numerous colleges nd universities. On the Continent, and particularly n Austria, systematic investigations on the cardio- gical side have been performed with a thoroughness hich experience of Teutonic discipline prepares us to xpect. But to select only a few outstanding names, eonard Hill, A. V. Hill, Pembrey, Barcroft, Haldane, nd Douglas have contributed results in this country s important as any of those of their transatlantic and ontinental colleagues. Above all, I feel that a special xpression of appreciation is due to the late Prof. ainbridge. I read his work, "The Physiology of uscular Exercise," on its appearance in 1919, but a ull appreciation is possible only by a re-perusal after a irly comprehensive survey of the general literature. o Prof. A. V. Hill I am personally indebted for much enerous assistance in elucidating several points.

An Address
ON
POST-OPERATIVE SEPSIS
IN GENERAL AND PUERPERAL SEPSIS IN PARTICULAR.

Delivered at the New Zealand Medical Association Meeting at Hamilton, N.Z., February, 1928,

By VICTOR BONNEY, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng.,
SURGEON TO CHELSEA HOSPITAL FOR WOMEN; ASSISTANT GYNÆCOLOGICAL SURGEON TO MIDDLESEX HOSPITAL.

When an operation "goes septic," the organisms causing the mischief are derived from one of two sources. Either they come from outside the patient's body or they are resident on or in the patient's body at the time of the operation. We describe the first of these happenings as infection from an extrinsic source, or more shortly, extrinsic infection; and we describe the second as infection from an intrinsic source, or intrinsic infection. For extrinsic infection to occur conveyance is a necessity, and the possible agents of this are the hands of the operator or his assistants, their saliva, their sweat or their hair, the instruments used, the ligatures and sutures inserted, the swabs, sheets or dressings applied, or even the dust of the room or theatre in which the operation takes place. For intrinsic infection to occur conveyance is not a necessity if the septic organisms are resident on the part actually operated upon, but it is a necessity when the part operated upon is initially aseptic and the organisms come from some other area of the body. The possible agents of conveyance in this event not only include the hands of the operator and his assistants, but also the blood stream and lymphatic stream of the patient, and all other currents and flows in his or her body which are capable of transporting bacteria. The problem of obtaining surgical asepsis, both during and after an operation, therefore, resolves itself into (1) obtaining initial sterility in the area operated on, and (2) preventing conveyance to the area of organisms potential for sepsis from elsewhere.

Initial Sterility.

Bacteria are normally resident over all the outer surface and most of the inner surface of the human body, the areas which are an exception to this rule being the interior of the uterus and the urinary tract down to the urethra, and probably also the biliary and pancreatic ducts and the smaller bronchi and pulmonary alveoli. The distribution of the bacteria is, however, very variable as regards their quality, for the organisms found on the skin are generally of low potential virulence except in certain areas, whilst those resident in the alimentary tract are of much greater potentiality for harm, especially in certain parts of it.

The same variation is observable in quantity. Thus the skin of the arms, chest, and upper abdomen contain few, as compared with the pubes; the fork and the inner sides of the thighs, and the stomach and jejunum few as compared with the mouth, colon, and rectum. Of all areas the lower bowel is normally most dangerous, not only because it is the most heavily infected, but because the organisms it contains are mostly of considerable potential virulence. It is obvious from the results which follow traumatic perforation of the gut, or bruising or strangulation of its wall, that even in the most healthy person the bowel organisms, far from being easily tolerated by the tissues in their immediate neighbourhood, are, in fact, held within bounds by a fence of tissue resistance so delicate that the least injury to it is followed by a dangerous invasion. Around the anus there exists a zone of skin whose bacterial content becomes more and more identical with that of the

lower bowel as the anus is approached. This can be proved by making cultures, but common observation shows it. If a game bird or hare is hung it is the fork, the inner and upper thigh that first becomes "high," and every surgeon knows that incision fringing on this area, such as the inner end of that for inguinal hernia, or the lower end of a subumbilical median incision, are points favoured by suppuration. This was strikingly exhibited in war wounds, as all who had charge of wounded men remember. The nearer to the anus, the greater the probability of grave infection.

The difficulty, therefore, of procuring initial sterility of an area to be operated upon varies very much, according to the anatomical position of that area. Skin can be sterilised by certain antiseptics, though the antiseptic must be applied for a far longer period than is usually deemed necessary; the average preparation of the skin for an operation, at most, achieves but a temporary surface sterility. As, however, the skin organisms are usually of very low potential virulence, this does not much matter, except in areas like the perianal zone, where it may matter a great deal.

The problem of procuring initial sterility of the inner surface of the body, as compared with its outer surface, the skin, is at present practically unsolved. No means are known at present of sterilising the interior of the bowel, or of the mouth, or of the naso-pharynx or nose, short of applying antiseptics in such concentration that they kill the surface they are applied to. The vagina is in a rather better case, for if it is not too heavily infected its surface can, I believe, be sterilised.

Preventing Conveyance.

Septic organisms are conveyed either by extraneous agency or by natural agency. Under the term "extraneous agency" falls all conveyance by the surgeon and his assistants, and also conveyance by dust, but fortunately this method of transportation must be very rare, for if not, surgery would be impossible. Experiments carried out by Andrews on the germ-content of the air of Oxford-street, in London, showed that pathological organisms were practically absent.

Under the term "natural agency" falls conveyance by the blood stream, the lymphatic stream, and all other natural flows capable of transporting organisms from one part of the body to another. Take, for example, a traumatic hæmatoma of a deep-seated muscle which presently suppurates. The muscle was almost certainly sterile at the time of injury, so that the organisms of suppuration must have been transported into the injured area from elsewhere, probably by the blood stream. Again, the organisms in a suppurating hæmatocele due to extra-uterine gestation probably come from the intestine by lymphatic transudation through its wall. Bond and others have shown that microscopical particles of indigo and carmine placed in the upper vagina are transported into the uterine cavity and even into the tubes by a current which apparently works along the walls of the canal in the reverse direction to the general flow.

The problem of preventing the conveyance of bacteria from extrinsic sources to the operation area is solved by the absolute sterilisation of all instruments, appliances, and material used at the operation, by the wearing of sterile gloves, masks, and gowns by the surgeon and his assistants, and by the observance of the recognised aseptic ritual of an operating theatre, which forbids anything already sterilised being brought into contact with any object not sterilised.

On the other hand, the problem of preventing the conveyance of bacteria from intrinsic sources to the operation area is very far from being solved. In certain operations a part of the area to be operated on can be made sterile to start with, while other parts cannot, as, for instance, in resection of the bowel, where the abdominal wall can be made sterile but the intestine cannot. To prevent transportation of organisms from the bowel to the abdominal wound the latter is elaborately shielded by sterile cloths or rubber. But even with such precautions the possibility of extraneous conveyance is only partially met, for bacteria may be, and probably always are conveyed from the interior of the bowel on to the peritoneum immediately adjacent to the line of intestinal suture. Fortunately dosage counts in infection; that is to say, the tissues themselves can deal with bacteria transported on to them, provided the number implanted be relatively small. The factor of tissue resistance comes into play as well as the essential virulence of the organisms, and this not only varies immensely in different individuals but depends on the treatment the tissues have received during the operation. Bruised, ecchymotic, half-strangled, and mauled-about tissue is much less resistant to bacterial assault than tissue that is uninjured.

The part of the problem, however, that at present almost baffles us is to prevent the transport of organisms from intrinsic sources on to the operation area by the natural agency of the currents and flow existing in the living body. For instance, we have not, nor, probably, shall we ever have, any means of preventing organisms transuding through the bowel wall into a pelvic hæmatocele, nor of preventing bacteria in the upper vagina ascending into the uterus. The dilemma has to be got over in other ways: first by seeing to it that the organisms resident in the patient's body, not only in the operation area but in all other areas, are of as low a potential virulence as possible, for then their transportation does not matter so much; and, secondly, since virulence is entirely relative to tissue resistance, by increasing tissue resistance or, at least, being careful not to lower it by unnecessary trauma. Tissues damaged to the degree of partial devitalisation may possibly have an actual attractive effect on bacteria. Another possibility is that transportation of organisms is always going on in the body fluids, but in such minute quantities that effects are only produced when there is some marked local lowering of resistance. Whichever be the explanation, it is certain that they increase enormously in damaged tissue not only in number, but in virulence.

The modern surgeon therefore prefers, if there is time, to abolish from the patient's body before the operation all harbourages of obvious sepsis, such as foul teeth and unhealthy tonsils, whilst he carefully avoids in the performance of the operation rough handling and tearing and all other force that unnecessarily bruises the tissue. As a result of the ever-increasing application of the principles I have summarised, the surgical results of to-day have very markedly improved on what they were 20 years ago, and they will continue to improve with every addition to our technique that makes for more perfect sterilisation of the operation area to begin with, greater certainty of preventing the conveyance to it of organisms during and after an operation, and increased delicacy in the handling of the tissues.

On Puerperal Sepsis in Particular.

The reason why I have begun this address with a dissertation on surgical asepsis in general is that childbirth is the operation whereby the neoplasm of pregnancy is removed, and puerperal sepsis is the condition produced by septic infection of the operation area.

The operation may be performed: (1) by the woman alone; (2) by the woman and obstetric surgeon in coöperation; and (3) by the obstetric surgeon alone. The first of these we call natural delivery, the second assisted delivery, and the third artificial delivery. Having then examined the mechanism of post-operative sepsis as it applies to all operations, let us see how it applies in particular to the operations that collectively come under the head of childbirth, remembering that sepsis follows an operation because either (*a*)

operation area was not initially sterile; or (*b*) infection from an extrinsic source occurred during or after the operation by extraneous agency; or (*c*) infection from an intrinsic source occurred during or after the operation by extraneous agency; or (*d*) infection from an intrinsic source occurred during or after the operation by natural agency.

Natural Delivery.

When Nature operates her instrument is the uterus itself, and this works in an area that is normally sterile. The possibilities of infection from an extrinsic source, or from an intrinsic source by extraneous agency, do not therefore exist. When sepsis follows labour, during and after which no interference has taken place, either the uterus was initially septic or septic organisms have been transferred to it by natural agency from the vagina or elsewhere. Initial sepsis of the uterus is probably extremely rare, but one occasionally sees cases of puerperal fever in which pyrexia was noted even before the onset of labour. That the uterus might become infected from an intrinsic source by natural agency before labour began must be allowed, when we consider infections like acute osteomyelitis and other analogous conditions which are almost certainly conveyed by the blood stream. Infection from the vagina, on the other hand, is much more likely, considering the proved fact that microscopic particles from the upper part of that canal can be transferred by natural agency into the uterine cavity. Indeed, it is probable that such transference always occurs, but because the number of bacteria so transferred is small, and the bacteria themselves are of low potentiality, they perish under the bactericidal effect of the blood and serum exuding from the uterus. On occasion, however, the vagina may contain bacteria of high virulence, and then such transference would be liable to lead to grave results.

The organism commonly responsible for puerperal fever is a streptococcus, usually of the hæmolytic group, and often identical with *S. pyogenes*. Since streptococcal vaginitis is a very common complaint, and streptococci can often be isolated from the vagina without any sign of inflammation being present, the fact that absolutely natural labour can be followed by sepsis need occasion no surprise. That it occurs relatively so seldom must, I submit, be due to the small number of organisms capable of being conveyed into the uterus by natural agency and their usual low virulence.

Assisted Delivery.

When the woman and the obstetric surgeon coöperate, the possibility of infection by extraneous agency, both from extrinsic and from intrinsic sources, becomes added to infection from intrinsic sources by natural agency. We should expect, therefore, on purely logical grounds, that assisted labour would show a higher sepsis rate than natural labour, and in fact it does, in spite of modern preventive measures.

Until quite recently extrinsic infection was held to be the usual cause of puerperal fever, in spite of the fact that the measures taken against it so successfully in other forms of surgery, such as the use of antiseptics and the wearing of gloves and sterile gowns, have been generally employed in midwifery for a good many years without greatly diminishing the total number of cases, though they have sufficed almost to abolish the epidemics which were frequent in lying-in hospitals and which occurred from time to time in the practice of individual obstetricians. The fact is that most puerperal sepsis is made up of sporadic cases bearing no relation to one another, and the relatively poor results obtained by measures directed simply against the occurrence of extrinsic infection, as compared with their striking results for epidemics, necessarily suggests that the ordinary sporadic, unlike the epidemic, case is not due, as a rule, to extrinsic infection at all, but to intrinsic infection.

The entrance to the vagina lies in a skin zone over which intestinal organisms are more or less thickly spread, and these organisms, even in the most healthy person, are potential for sepsis. The bacterial content of the lower bowel represents the drainings from the whole of the alimentary canal, including the mouth, teeth, tonsils, pharynx, and appendix, so that in infective conditions of any of these the causative organisms are swallowed and presently attain the lower bowel and hence the skin in the neighbourhood of the vagina and vulva.

In assisted labour the vagina forms, as a rule, the main field of the operation, so that the surgeon not only has to work through and in an area which may initially contain organisms of potential virulence, but one to which the approaches are always more or less heavily infected. Therefore, even if he succeed in procuring asepsis of the vagina to begin with, he is still faced with the difficult problem of preventing infection during the operation by the manual carriage of organisms from its approaches. The greatest danger lies in introducing hands or instruments into the uterus, for then septic organisms can be implanted directly on the placental site, but even if they be carried merely as far as the upper vagina, a risk remains that they may be transported into the uterus by the natural mechanism.

The much greater frequency of tissue damage in assisted, as compared with natural, labour is another factor which deserves close consideration. Tears of the cervix, vagina, and perineum occur in natural labour, but with much less frequency than in assisted labour. Nor, on the average, are the tissues in their neighbourhood nearly so much bruised and devitalised, because they are not subjected to so much force. Severe tissue damage, because it forms a good nidus for the growth of organisms, is always dangerous, and is most especially so when the upper vagina and cervix are involved.

Artificial Delivery.

Two operations fall under this head, accouchement forcé and Cæsarean section.

In accouchement forcé the neoplasm of pregnancy is taken away through the vagina by the surgeon unaided, exactly as a submucous fibroid might be removed. The operation is not only a very severe one, involving great tissue damage, but it is carried out in an area which it is difficult to sterilise initially and very difficult to protect against the manual carriage into it of organisms from its heavily infected approaches. Practical experience bears out logic, for this is of all forms of delivery the most often followed by severe septic infection, and this would be the more apparent were it not that a large proportion of the patients operated on die by shock or hæmorrhage before sepsis has had time to develop.

There is another method of rapidly emptying the uterus called vaginal Cæsarean section, in which the cervix and lower uterine segment are deliberately incised from below, and sutured up afterwards. It is a difficult operation, only performed by practised obstetric surgeons, and it is less liable to be followed by sepsis than the classical accouchement forcé. There would appear to be two reasons for this. First, since it is carried out in operating theatres only and by very expert surgeons, the antiseptic technique employed is probably superior to that of accouchement forcé, which is usually performed under bad conditions. Secondly, the tissue damage inflicted is much less severe, clean-cut wounds replacing the bruised lacerations which the older operation necessitates.

In Cæsarean section by "election," which is performed either before or just after labour has begun, the vagina is shut out from the operative field, and as the uterine cavity is normally sterile and the abdominal skin can be rendered sterile or cut out of the operative field altogether, the surgeon works in what, from the point of view of asepsis, is an ideal area. The risk of extrinsic infection is deleted by the aseptic ritual of an operating theatre, whilst

the possibility of intrinsic infection by extraneous agency is rendered practically non-existent by the preparation and draping of the abdominal skin, so that only intrinsic infection by natural agency is left unguarded against. Though it is possible, after Cæsarean section, for organisms in the upper vagina to ascend spontaneously into the uterus and infect both the sutured wound and the placental site, the event is an uncommon one, and post-operative sepsis, which occurs after an operation performed with all the proper safeguards, is usually due to organisms finding their way across the peritoneal cavity from the intestine to the sutured uterine wound. This is analogous to what takes place when a hæmatocele becomes infected, and is probably brought about either by oozing from the uterine wound after the operation is finished, or by the partial strangulation of part of the uterine wall by ill-placed sutures. When such a misfortune occurs, the symptoms are those of a local inflammation of the uterine wound. Placental site infection giving rise to the symptoms of typical "puerperal fever" is very rare indeed.

When, however, the operation is performed after the cervix is open to the vagina the case is very different. We will call this Cæsarean section by "compulsion," since, on account of the considerable risk of post-operative sepsis that accompanies it, it is not performed unless the surgeon is compelled. This sepsis might be expected for far more menacing routes of infection exist in addition to those possible in the "operation of election." It was shown by Routh, from actual figures, that the risk of sepsis after Cæsarean section increases progressively with the time over which the uterine and vaginal cavities have been in continuity, and depends still more upon the amount of intravaginal manipulation that has been practised beforehand. This is the experience of all surgeons. The open cervix no doubt makes spontaneous organismal ascent more easy, and allows the head of the child to be fouled, so that it infects the uterine cavity as it is pulled up. The time factor would merely operate by increasing the period over which organisms might spontaneously ascend, but the ill-effects of previous manipulation and instrumentation can only be due to the carriage of organisms from the perivulval and perianal skin into the vagina and cervix. No matter how carefully the surgeon who carries them out is gloved and gowned, the danger is at the best only partly abrogated. It is the most striking proof we have of the reality of intrinsic infection by extraneous agency, and makes clear the reason why assisted labour is more likely to be followed by sepsis than natural labour.

SUMMARY.

Typical puerperal fever is least common after absolutely uninterfered-with labour and after Cæsarean section by election, in both of which the only risk that cannot be guarded against is intrinsic infection by natural agency. It is commoner after assisted labour, because an additional risk, which cannot easily be guarded against, is added—namely, the risk of intrinsic infection by extraneous agency. This is rendered more serious by the tissue damage, often severe, that is inflicted by the operation. It is commoner still after Cæsarean section by compulsion, because the uterus is directly infected as the child's head is pulled up, and is commonest after accouchement forcé, because severe tissue damage is invariably inflicted and the uterus is directly infected as well.

CONCLUSIONS.

The first conclusion to be drawn from the facts we have considered is that in obstetric, as in general, surgery there is no royal road to the abolition of post-operative sepsis. The routes and modes of infection are too many and too complicated to be countered by a single method of prevention. The organism commonly responsible for puerperal fever is a streptococcus, and it is, I think, generally admitted that pregnancy lowers the body resistance to this organism in a special degree. The streptococci found in puerperal fever have been closely studied in the endeavour to trace their place of origin, bu no consensus of opinion has been reached, nor is of primary importance. The killing of all streptococ and other organisms of sepsis, both local to the patie and local to the surgeon, is obviously the grand idea but its achievement is beyond our powers at presen The main harbours of sepsis, however, are known t us and must be attacked; the routes and modes infection which I have described can to a large exte be stopped up or countered, whilst tissue resistan must be exalted if a method can be found, and in th meantime preserved at its highest possible level b avoiding all unnecessary tissue damage.

Of the five operations by which the neoplasm of pregnancy may be removed, natural uninterfere with delivery is the one most desirable, for althoug Cæsarean section by election is no more likely to b followed by sepsis, it has certain other drawbac and risks. Unfortunately, Nature's operation inefficient for a certain number of cases, and assiste delivery has to take its place, in spite of the fact th its sepsis rate is a higher one. It should not therefo be resorted to until it is quite clear that the uter is unequal to its task, and the surgeon must tak every possible precaution to abrogate the risks th his entry on the operative field entails. This ca only be achieved by an antiseptic technique f more thorough than that commonly employed. Th wearing of sterile gloves, gowns, and the use of ant septic lotions are measures most efficient again extrinsic infection, but so long as a single organis remains unkilled in the vagina, or unkilled uncovered in the skin surrounding the entrance the vagina, the risk of intrinsic infection by th agency of the surgeon remains. The problem s us is indeed a difficult one, but until it is faced n only by every practising obstetrician but by th armchair critics and the State, no striking fall the yearly death-rate from puerperal sepsis can expected. If the operation were for the removal of large fibroid by the same route, the patient would fully anæsthetised in the lithotomy position on operating-table, with an assistant standing on eith side; all but the entrance to the vagina would heavily draped with aseptic cloths, the exposed sk and the entire surface of the canal would have be soaked with a powerful antiseptic, whilst the surgeo carefully gloved, gowned, and masked, would operat sitting in the best possible light. If this is the ide for the removal of one neoplasm it must surely for the other.

I have spoken as an idealist, but I am as conscio as anyone of the difficulty of attaining in obstetri what in other branches of surgery is the accept routine of practice. I have in the past written oft and strongly of these difficulties, and I have insist that they can only be removed when the lay pub realises that childbirth is a surgical operation requiri for its proper conduct the full gamut of surgic requirements. My object here has been to lay ba the processes whereby a woman becomes sep after childbirth, so that, clearly understanding the each obstetrician can think out for himself t solution of the problem with which he is faced.

WAGE-EARNERS' CLUBS.—Mr. W. H. B. Fletche chairman, speaking at the Chichester County Sessions Feb. 7th, said there was evidence of an increase in t reasonable use of licensed premises, and a tremendo decrease in the abuse of alcohol. There was a great deal improvement going on to the outside of licensed premis and he hoped it was being accompanied by improvemer inside also. The public-house was the club of the wag earning class. It was the place where they had opportu ties of social intercourse with their friends and neighbou which they could not get elsewhere, and he could not h feeling very strongly indeed that those who used the publ house as their social club had a right to look in those publ houses for something of the same amenities which the people got who were able to go to sumptuous restauran clubs, and hotels. If publicans and brewers would their part to carry out improvements that might possible. The sympathy and coöperation of the public in doing, Mr. Fletcher concluded, was assured.

POSTURE OF THE HAND IN CHOREA

AND OTHER STATES OF MUSCULAR HYPOTONIA.

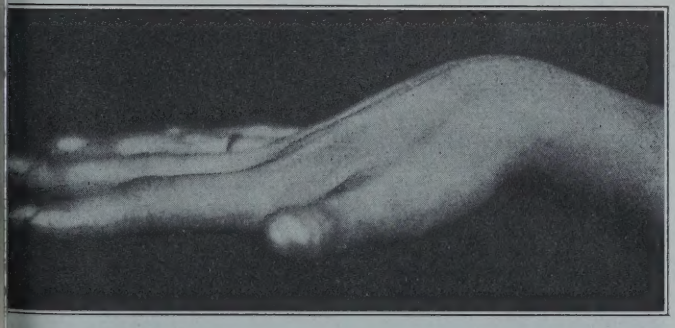
By W. RUSSELL BRAIN, M.D. Oxf., M.R.C.P. Lond.,

SISTANT PHYSICIAN TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

(*From the Medical Unit, the London Hospital.*)

THE posture of the outstretched hands often hibited by patients suffering from chorea is one of ie most familiar of abnormal attitudes. It is aracterised by flexion at the wrist and hyper-tension at the metacarpo-phalangeal joints. The gers are either straight or slightly flexed the interphalangeal joints, and separated, id the thumb is hyperextended and ducted (Fig. 1). This posture seems first have been described by Warner [2] in 1885 id has recently been the subject of con-deration by Wilson,[3] who has offered what pears to be the only proposed explana-on. He points out that the posture of ie hand in chorea is the "corresponding posite" of the normal resting posture of ie hand—namely, extension of the wrist id flexion of the fingers—and he concludes iat "a physiological shift" has occurred from one posture to its corresponding posite." He believes that "the demonstra-on of this physiological 'shift' in the case chorea can fairly be taken to argue a ndition of abnormal function of the rtico-spinal system, though with the mediate proviso that this abnormal state ed neither be of a structural sort nor have its timate origin on the motor or effector side." While agree with Wilson that the posture of the hand in orea is the corresponding opposite of the resting titude of moderate flexion of the fingers and

FIG. 1.



"Choreic" posture of the hand, characterised by flexion of the wrist and hyperextension of the metacarpo-phalangeal joints with separation of the fingers, in a patient suffering from chorea.

xtension of the wrist, I believe that it is merely the xaggeration of a normal posture, and that this xaggeration has a much simpler physiological xplanation than the one which he proposes. To emonstrate this it is necessary to examine the nergic distribution of muscular contraction in certain rmal movements and postures of the hand and ngers.

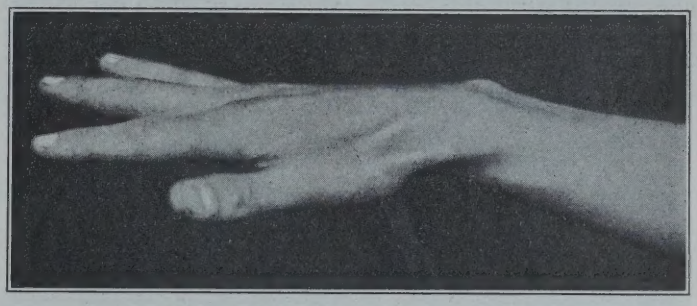
The Muscular Components of Movements of the Fingers.

I shall describe as a "movement" the total set of uscular contractions which are at any time mutually mbined, and I shall regard such a movement as nsisting of certain constituents—namely, the tions of the prime movers or agonists, of the nergists, including fixation muscles, and of the antagonists. The three movements with which we have to deal are: (1) flexion of the fingers; (2) extension of the fingers without separation; and (3) separation of the fingers and thumb.

1. *Flexion of Fingers.*—This movement involves what is perhaps the most familiar example of synergic muscular contraction. The prime movers are the flexors of the fingers and the synergists are the extensors of the wrist. The long flexors of the fingers are also flexors of the wrist. If in flexing the fingers they are allowed also to flex the wrist this action, by approximating their origin and insertions, weakens their action as flexors of the fingers. Synergic extension of the wrist therefore strengthens the grip.

2. *Extension of Fingers without Separation.*—This is a movement which occurs in such actions as sweeping crumbs from a table with the back of the hand. The prime movers are the extensors of the fingers and the synergists the extensors of the wrists, extension of the fingers flowing naturally into extension of the wrist.

FIG. 2.

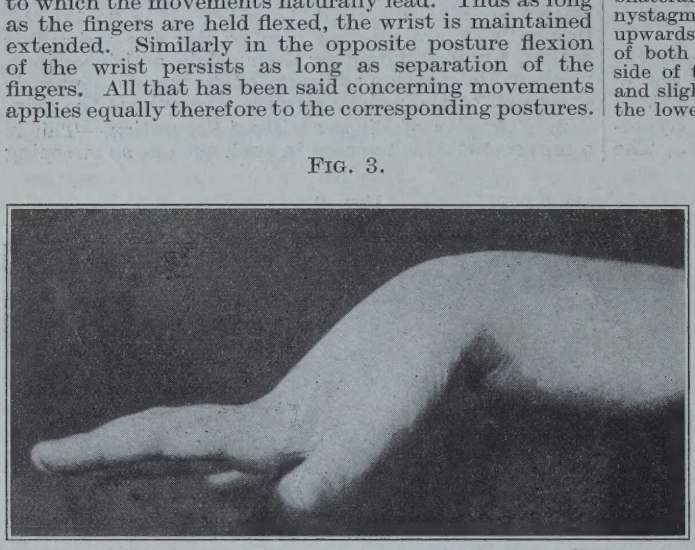


Synergic flexion of the wrist in association with separation of the fingers in a normal person.

3. *Separation of Fingers and Thumb.*—In this movement the prime movers are the dorsal interossei and the extensors of the fingers, and the abductors and extensors of the thumb. The synergists are the flexors of the wrist. This movement must be analysed in some detail, since it is the foundation of the "choreic" posture of the hand. The rôle of the extensors of the fingers as abductors is exemplified in the "trick" movement by which a patient with paralysis of all the small muscles of the hand may yet be able to abduct his fingers, provided he is not made to keep their palmar aspect in contact with a plane surface. But the extensors of the fingers are also extensors of the wrist, and unless the latter action is counterbalanced their value as extensors and abductors of the fingers is greatly reduced. This can be demonstrated by attempting to extend and separate the fingers when the wrist is maintained passively dorsiflexed. Thus synergic flexion of the wrist assists abduction of the fingers in exactly the same way as synergic extension of the wrist assists digital flexion. Consequently, while it is true that extension and abduction of the fingers with synergic flexion of the wrist is indeed the corresponding opposite of flexion of the fingers with synergic extension of the wrist, it is just as natural and physiological a movement as the latter. It is curious that Wilson should have failed to recognise this, since in the same communication in which he stresses the pathological character of the "choreic" posture of the hand he includes the following in a list of normal movements: "open closed hand; extensors of wrist relax, flexors of wrist contract."[4] In opening the closed hand this contraction of the flexors of the wrist is synergic with the contraction of the extensors and abductors of the

fingers, and is part of the very movement which elsewhere he regards as the result of a pathological "physiological shift." Fig. 2 illustrates the synergic relationship of flexion of the wrist with extension and abduction of the fingers in a normal person. The synergic relationships which exist between the muscular components of the movements we have just been considering are to be found also in the postures to which the movements naturally lead. Thus as long as the fingers are held flexed, the wrist is maintained extended. Similarly in the opposite posture flexion of the wrist persists as long as separation of the fingers. All that has been said concerning movements applies equally therefore to the corresponding postures.

FIG. 3.



"Choreic" posture of the hand in a patient suffering from a tumour of the pons and exhibiting marked hypotonia.

Relation of the "Choreic" Posture to Hypotonia.

Though the "choreic" posture of the hand is normal in its synergic pattern, its exaggeration renders it pathological, and it is this exaggeration which brings it into relationship with muscular hypotonia. Hypotonia is as characteristic a symptom of chorea as involuntary movement. To demonstrate this hypotonia clinically we have recourse to passive movement, and show that in chorea the segments of a limb can be passively displaced at the joints to a much greater extent than normally, the resistance to such displacement being much diminished. We recognise in muscle tone that state of muscular contraction which underlies posture, and which therefore constitutes a resistance to the passive displacement of a limb or its segments. In a normal person who is voluntarily relaxing his muscles this resistance is extremely slight, but its existence is proved by the occurrence of states of hypotonia, such as chorea, in which the resistance to passive movement is much less than normal. Muscle tone plays a part also in active movement. It is not necessary here to discuss to what extent the antagonists of the prime movers undergo reciprocal relaxation, for those who hold that they do would probably admit that they do not become completely atonic, but retain a residuum of tone which ensures steadiness to the movement. In hypotonic states, owing to the reduction of this tone, active movement, like passive displacement, meets with abnormally little resistance from the antagonists. Certain consequences of this are discussed by Holmes in his analysis of the symptoms of lesions of the cerebellum.[1] Here I would only point out that this hypotonia of the antagonists leads to an exaggeration of postures voluntarily adopted, since the prime movers lack the check which is exercised by antagonists of normal tone. I believe that the so-called "choreic" posture of the hand is such an exaggeration of a normal attitude. Its relationship to hypotonia is confirmed by the fact that the same attitude may be observed in patients wh exhibit hypotonia as a result of conditions other tha chorea. Fig. 3 shows a pronounced example of th attitude in a child who presented the clinical picture a tumour of the pons and who showed marked hyp tonia but no choreiform movements.

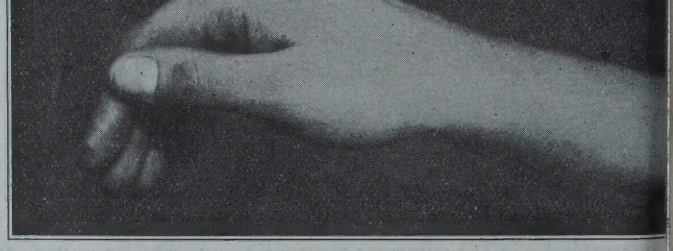
A girl, aged 11, began to suffer three years ago fro headaches, vomiting, and unsteadiness of gait. There w bilateral secondary optic atrophy of moderate severit nystagmus on conjugate deviation to either side ar upwards, bilateral weakness of the external recti, weakne of both sides of the face and soft palate, and of the le side of the tongue. The upper limbs exhibited hypoton and slight intention tremor, more marked on the right side the lower limbs were slightly hypertonic and showed son loss of voluntary power, with exaggerated tend jerks. The right plantar reflex was doubtful, th left extensor. There was no sensory loss. Th gait was ataxic.

The "choreic" posture of the hand is als frequently to be observed in hyperth roidism, in patients suffering from anxie neurosis, and in hypotonic children. constitutes a simple and readily apprec ated visible indication of muscular hyp tonia, which is of considerable value in th routine examination of patients.

Lastly, it must be noted that there is n tendency in chorea to the suppression the resting posture of moderate flexion the fingers with synergic extension of th wrist, nor of its conversion into its corr sponding opposite. The choreic patie remains capable of this attitude, as Fig. shows, and if asked to hold out the han is as likely to adopt this posture as i opposite. It is, indeed, often necessa to tell the patient to separate his finge in order to elicit the "choreic" posture.

Since the "choreic" posture of the hand is simp an exaggeration of a normal attitude produced by th muscular hypotonia and is, moreover, not associat with any suppression of the resting posture of whi

FIG. 4.



Normal resting posture of the hand in a patient suffering from chor (same patient as in Fig. 1).

it is the corresponding opposite, I cannot accept t view that it affords evidence for the existence of "physiological shift" or "abnormal function of t cortico-spinal system" in chorea. The fact that t same exaggeration of this posture occurs in oth hypotonic states renders the term "choreic postu of the hand" or "choreic hand" misleading. better descriptive term would be "hypotonic postu of the hand," which has the advantage of stating cause and indicating the conditions in which it is be found. In spite of some disadvantages this probably the most convenient description for gene use.

Conclusions.

1. The "choreic" posture, of flexion of the wr and hyperextension at the metacarpo-phalang

ints, is a normal synergic muscular relationship. It differs from the normal posture only in being xaggerated. 3. This exaggeration is the result of ie hypotonia of the antagonistic muscles, which in irn is a local manifestation of the general hypotonia ccurring in chorea. 4. The same exaggeration of is posture is to be found in other states associated ith hypotonia. 5. The "choreic" posture affords evidence for the existence of a "physiological ift" in chorea, nor of any disturbance of the cortico-inal system, being entirely explained by the hypo-nia. 6. The term "choreic posture" is misleading, id the phenomenon would be better described as the hypotonic posture of the hand."

ON THE PATHOGENESIS OF DYSTROPHIA MUSCULORUM PROGRESSIVA.

BY KEN KURÉ, M.D.,

PROFESSOR OF CLINICAL MEDICINE IN TOKYO IMPERIAL UNIVERSITY, JAPAN.

I HAVE read Dr. Edwin Bramwell's Bradshaw ture [1] on the Muscular Dystrophies, Sympathetic stem, and Endocrine Glands with deep interest as nave been engaged in the study of muscular tone, ecially the trophic influence of the sympathetic ervation on the muscle; the first positive evidence this was reported at the Tokyo Medical Society in ptember, 1924. Our studies have been published ially in the *Zeitschrift für die gesamte Experimentelle edizin* since February, 1925, and Westphal [2] has ently published his opinions on the muscular strophies. I venture to present a summarised count of our investigations.

In an earlier paper [3] I expressed the opinion that ogressive muscular dystrophy may be caused by ions of the autonomic innervation of the voluntary scle. This was based upon the experimental fact at in dogs dystrophy of leg muscles was produced extirpating the abdominal sympathetic chain, and at the dystrophic changes were accelerated by ting the corresponding posterior roots at the same e. This effect of the posterior roots was found later be due to the parasympathetic innervation of the scle. Further, we found that severance of the chorda npani (parasympathetic) caused dystrophy of the gue muscles,[4] while extirpation of the cervical npathetic system produced dystrophic changes in facial muscles.[5] Especially interesting is the fact at extirpation of the ganglion ciliaire [6] produced a ical dystrophic feature in the eye muscles within out 40 days, a very short interval compared with months which experimental dystrophy took to pear in the limb muscles. In 6 patients out of 21 ose cervical sympathetic trunks had been extirpated various therapeutic purposes, we [7] found marked ophy in the trapezius, deltoid, and pectoralis major eral months after operation, and histological mination revealed typical dystrophic changes. The per arm muscles were occasionally involved, but forearm and hand muscles were always free. The son why muscular dystrophy did not appear in all operated cases may be the difference of muscular ervation in different individuals—i.e., vagotonic sympatheticotonic. In the latter class, since their scles are chiefly under the trophic influence of the npathetic innervation, the resection of this supply uces muscular dystrophy.

The conception that muscular dystrophy is induced derangement of the autonomic innervation of the scle may explain various pathological problems. cases of amyotrophic lateral sclerosis, spinal progressive muscular atrophy, and neurotic muscular atrophy, the muscles of the forearm and hand are mostly involved, while in dystrophia musculorum progressiva the muscles of the face, shoulder-girdle, and thigh are affected, but the small muscles of the hand and foot, as well as the gastrocnemius, are nearly always left intact. Babinski and Onanoff [8] tried to explain the degree of predisposition to muscular dystrophy by the degree of rapidity of muscular development. We [9] have found in rabbits, dogs, monkeys, and human corpses that the creatin content of the hand and forearm muscles is less than that of the muscles of the thigh, upper arm, and back. On the other hand, the creatin content of the diaphragm in dogs was found to rise with the increase and to fall with the decrease of sympathetic tone.[10] This fact was amply verified in the skeletal muscles.[9] Further, we [11 12] have established in human corpses that the number of sympathetic fibres—i.e., Remak's fibres—in peripheral nerve varied considerably according to the muscle innervated. According to Hatano, N. phrenicus, NN. intercostales, N. muscularis for M. pectoralis major, M. gluteus maximus, and M. quadriceps femoris contain a number of sympathetic fibres, while rami musculares for M. policis brevis and MM. lumbricales contain only a few sympathetic fibres. This fact seems to supply an important clue to the problem of the characteristic localisation of muscular atrophy in the diseases mentioned. We have already shown that, when the autonomic innervation of a muscle is left unimpaired, muscular atrophy is inhibited in the diaphragm [13] and the muscles of the tongue,[4] eye,[6] and face [14] when the motor fibres are cut. Similar results were obtained by Boeke [15] and Agduhr [16] for the eye and intercostal muscles. It is therefore easy to understand why, in the first group of muscular atrophy mentioned, the hand and forearm muscles, which have less sympathetic innervation, are affected first and most intensely. Indeed, in four cases of amyotrophic lateral sclerosis and one case of spinal progressive muscular atrophy we [3] have proved that the sympathetic innervation of the atrophic muscles remained intact. In dystrophia musculorum progressiva, however, the autonomic innervation of muscle is impaired, and the muscles which have more sympathetic innervation are affected earlier and more intensely than those which have less. The eye and respiratory muscles are evidently exceptions, because, notwithstanding their ample autonomic innervation, they are affected seldom or late. As described above, extirpation of the cervical sympathetic trunk causes dystrophy of the muscles of the shoulder-girdle, and eventually of the upper arm, while the forearm and hand muscles nearly always remain unchanged. Moreover the muscular tone and tendon reflex of the sympatheticotomised muscles decrease just as in dystrophia musculorum progressiva [5]; both the sympatheticotomised and dystrophic muscles become easily tired, but are readily restored by the administration of adrenalin, which will not, however, eliminate the fatigue of a normal muscle.[17] It is a well-known fact that a dystrophic muscle shows neither fibrillar contraction nor electrical R. D. According to Matsuura,[18] a sympatheticotomised muscle, although in a state of distinct atrophy, shows only a simple decrease of electrical excitability without any indication of R. D. or fibrillar contraction. From these numerous facts we regard it as highly probable that dystrophia musculorum progressiva is due to degeneration of the autonomic innervation of voluntary muscles.

We [3] have found, in two post-mortem examinations of dystrophia musculorum progressiva, fairly distinct changes in the sympathetic chain and sympathetic fibres in the peripheral nerves. Hitzig [19] reported many years ago a case in which he observed a marked dystrophy of the right and a slight change in the left cervical sympathetic system. It is desirable, therefore, to pay special attention to the autonomic innervation of muscles in the post-mortem examination of dystrophia. Further, in coöperation with Matsuura, I

found that extirpation of the spinal ganglion produced muscular dystrophy in the hind legs of dogs.[20] This must be due to the removal of the intermediate ganglion of the centrifugal parasympathetic fibres in the posterior root.[21]

Classification of Muscular Dystrophies.

Muscular dystrophies can be brought about by the affection at various places of the autonomic innervation of muscle. First, affection of the nerve end-plate must be mentioned. It is also possible that dystrophy may be caused by the alteration of Boeke's accessory end-platelets, although this has not yet been proved. Secondly, change in the sympathetic chain, and the sympathetic as well as the parasympathetic fibres in the peripheral nerve constitute a group to which belong Hitzig's case, two of our cases of dystrophia musculorum progressiva,[3] and muscular atrophy in six sympatheticotomised patients. Thirdly, changes in the autonomic nuclei of the spinal cord comprise a group to which belong the various cases reported by Erb [22] as dystrophies resulting from lesion in the spinal cord—i.e., the cases of W. Müller (degeneration of the anterior grey column), Dejerine (two cases of infantile spinal paralysis), Joffroy and Achard, Hitzig, Kawka (infantile spinal paralysis), Oppenheim (poliomyelitis anterior chronica), dystrophia musculorum progressiva after poliomyelitis anterior acuta; a case reported by Kaumheimer [23] (who found five similar cases in older reports), and our case.[9] As described above, muscular dystrophy occurs after extirpation of the cervical sympathetic trunk in a post-apoplectic spasm. Matsuura [18] has observed that total crushing of the spinal cord combined with extirpation of the abdominal sympathetic chain produces muscular atrophy fairly quickly, and it is therefore possible that dystrophia musculorum progressiva can be produced as a complication of a lesion of the pyramidal tract. Jendrassik [24] has reported a case of paralysis spinalis spastica accompanying muscular dystrophy.

A. Westphal [2] recently reported a case of dystrophia musculorum progressiva with the extrapyramidal symptom-complex, and suggested that the coexistence of these apparently different syndromes may be due to lesion in the mid-brain where the higher centre of the autonomic system is to be found. He is inclined to think that the higher centre for the autonomic muscular tone lies in the mid-brain, but I would suggest that the higher centre for the parasympathetic muscular tone is in the mid-brain, and actually in the hypothalamus, because parasympathetic muscular tone is not a necessary accompaniment of Parkinsonism. We are convinced, by the ample experimental evidence [23 24 25 26 27 28] which has accumulated in the last few years, that the cerebellum, and indeed Deiter's nucleus, is the site of localisation of the higher centre for sympathetic muscular tone. On the other hand, Jendrassik [24] has pointed out that dystrophia musculorum progressiva is found in association with Friedreich's disease, and gives as examples the cases of Joffroy, Dejerine, Erlenmeyer, Gowers, Mendel, and Ormerod, besides two cases of his own. Bing [29] has also reported a similar case. The autopsy of a case of Friedreich's disease which had been observed for 20 years by my predecessor, Prof. Irisawa, revealed the dystrophic alteration in muscles and the typical changes in the cerebellum (which was conspicuously small) and spinal cord. I propose, therefore, to classify such a form of dystrophy, due to the lesion in the cerebellum (the centre for the parasympathetic innervation of muscle) and mid-brain (the centre for the parasympathetic innervation of muscle), as the fourth group, which corresponds to amyotrophic lateral sclerosis caused by lesion of the motor innervation of muscle. Further, in coöperation with Matsuura [21] I found that extirpation of the spinal ganglion produced muscular dystrophy in the hind legs of dogs. This must be due to the removal of the interposing ganglion of the centrifugal parasympathetic fibres in the posterior root.

Clinical and Laboratory Notes

A NOTE ON THE LATEST DEVELOPMENT IN STEREOFLUOROSCOPIC WORK.

By F. Howard Humphris, M.D. Brux., F.R.C.P. Edin., D.M.R.E. Camb.

When Prof. Roentgen showed in Wurzburg 1897 his X ray discovery and demonstrated its val for looking within the body, it was said then hc wonderful it would be if the various shadows could shown in plastic form rather than as a flat silhouett Progress in this direction has been hampered several ways; the law governing stereofluoroscoj has not been fully recognised. The law stated simp is that angles of vision which the X rays make wi the body should be identical with those made by t vision of the observer of the body.

Among other difficulties which have retard progress is the fact that early in the days of X ra the tubes were of a size which rendered stereofluor scopy impossible. The gas tube, unwieldy in size ar uncontrollable in action, was unsuitable for stere fluoroscopy. Caldwell, of New York, struggled wi the problem in spite of other difficulties with sca success until the advent of the Coolidge tube. I fully recognised the value of stereofluoroscopy a he constructed the first workable, though imperfe apparatus for this branch of work, which was us chiefly for the localisation of foreign bodies during t war. In London during this period there was apparatus similar in principle designed for use wi coils, but difficulty arose here too, in that the tub if large enough to stand up, were too large to appro mate, and if small enough to approximate failed radi graphically. The advent of the hot cathode tube h rendered success in this direction possible, anoth assistance being the production of new scree eliminating phosphorescence. These may have fulfill their mission during the war, but were quite inadequa for the finer scientific work required in peace time f the full development of diagnostic X ray work.

The X ray diagnostician must have always had t feeling that there was something wanting, and c

never have felt satisfied with the flat shadow, especially in lung conditions where even the best stereoscopic plates gave an unsatisfactory result, because of the time which hitherto has elapsed between the two required exposures and the inevitable movement which must take place in it. Even the most satisfactory, accurate radiogram of the lungs only gives one position of a more or less rigid lung. With this, the most flexible of all organs, a stereoscopic vision is important—for example, in a lung with an old artificial pneumothorax, apparently cured, with a sputum free from T.B. it is important to see what adhesions there may be and in what position they are and what the flexibility is.

Other occasions for viewing moving organs, such as the duodenum for example, readily occur to one. This necessity has urged scientists and engineers to attack the problem afresh—employing new tubes, new screens, and adapting apparatus to the law governing stereofluoroscopy. Such an apparatus I have recently examined in Munich. It was exhibited in Wiesbaden in the spring of last year at the X ray congress held in that city, where it was declared that if successful it would be of the utmost importance in all future X ray diagnosis. Of this invention of Mr. F. E. Bornhardt I have made a careful examination and have seen two of them in good working order, one at Krankenhaus Rechts-der-Isar and the other at the Lungenfürsorge Anstalt in Halachin in Munich; of these I append a brief description. The apparatus consists of two specially constructed X ray tubes small in diameter placed side by side and connected with an alternating current supply in such a way that they emit X rays alternately. These impulses fall upon a fluorescent screen producing two shadow images of a body, placed between tubes and screen. The observer views the screen through a mechanical device—with a diaphragm rotating before the eyes in synchronisation with the two impulses from the X ray tubes—the result is that one eye sees the image produced by one tube and the other the image from the other tube, the physiological action of the brain combines these two pictures into one plastic impression. The movements seen on the screen appear to be continuous, as each eye is supplied with 50 pictures per second. The electrical supply is the usual A.C. and the X ray impulses from the tube and the opening of the diaphragms being of the same origin are in synchronism. A part of the mechanical construction consists of a device whereby the angle of the X rays to the body is rendered identical with that of the angle of vision, this being so whether the observer approaches the patient or recedes from him.

Having seen this apparatus when working I feel that the solution of the problem of satisfactory stereofluoroscopy has been attained.

A CASE OF SYPHILIS OF THE UTERUS.

By Hannah Billig, M.B., B.S. Lond.,
ASSISTANT CLINICAL PATHOLOGIST, ELIZABETH GARRETT ANDERSON HOSPITAL.

Very few cases of syphilitic disease of the uterus other than primary chancres of the cervix have been described. The following case, which was under the care of Miss E. Sylk at the Elizabeth Garrett Anderson Hospital, is therefore of sufficient interest to be recorded.

The patient, a married woman aged 35, was admitted in September, 1927, complaining of left-sided pain radiating down the leg. She had one child 6 years old and had had three miscarriages in January, April, and September, 1926. Since November, 1926, her periods had been regular and the loss had been normal. Previous to her marriage her periods had always been regular with normal loss. Except for rheumatic fever at 18 and an appendicectomy in 1924 she had been fairly healthy, though anæmic. There was no history of sore-throat, alopecia, or skin rashes, except for a single patch of psoriasis on her arm, present for the last five years. The husband was healthy and gave no history of syphilis. On admission general physical examination revealed no abnormality other than a palpable spleen. The uterus was enlarged and bulky. Fibroids were diagnosed and Miss Sylk performed a panhysterectomy with removal of both tubes and ovaries, as at the operation the appearance of the fibroid was strongly suspicious of sarcoma. Her recovery was uneventful.

Macroscopic Examination of the Uterus.—The uterus measured 5 in. by 4 in. by 3½ in. and showed a mass on the right side situated in the fundus and projecting subperitoneally. This mass, which was 2½ in. in diameter, had the "ham fat" appearance associated with sarcoma, but had a very irregular and angular edge. The uterine wall was much thickened, the wall of the fundus being 1½ in. thick.

Microscopic Examination.—Section of the tumour mass on the right side showed a necrosis of the muscle-fibres, bounded by a richly cellular zone showing miliary and conglomerated gummata. The myometrium was so infiltrated by lymphocytes and endothelial cells that the muscle-fibres were separated. Section through the fundus showed the myometrium infiltrated with gummata of varying size, mostly miliary. The muscle-fibres were separated by lymphocytic infiltration. The smaller vessels and capillaries were dilated and showed a perivascular collection of lymphocytes and plasma cells of varying extent, the beginnings of small gummata. The walls of the medium-sized vessels were much thickened, the medial coat showing most change. The endometrium showed slight increase in thickness. Miliary gummata were present throughout, but the reaction was much less marked than in the myometrium. Sections through the right uterine vessels showed very markedly increased thickness of the walls, chiefly of the intimal coat. The vasa vasorum were dilated and showed perivascular infiltration with lymphocytic cells. There was some increase in the subendothelial tissue. Some vessels showed subendothelial plaques with proliferation of the media and some showed almost complete obliteration of the lumen. The smaller vessels showed well-marked perivascular reaction with the formation of gummata. This reaction extended throughout the surrounding myometrium with formation both of miliary and diffuse gummata. The necrosis of the wall appeared to be due to the cutting off of the blood-supply by the changes in and around the vessels supplying this area.

Sections of the tube showed a similar gummatous reaction in the subserous and muscular coat. The larger vessels showed thickening of the media and perivascular infiltration round the vasa vasorum. The plicæ were somewhat thickened, but not adherent. There was some endothelial interstitial tissue reaction.

Sections of the ovary showed only increased fibrous tissue and corpora albicantes.

Sections were stained by the Ziehl-Neelsen method for tubercle bacilli and by the Levaditi and Fontana methods for spirochætes, with negative results. The Wassermann and the Sachs-Georgi reactions were positive in the patient, but the husband's blood was negative.

Hoffmann described the only case I could find at all similar to this.

His patient, admitted with chronic sepsis following the delivery of living twins, showed a necrotic tumour the size of an apple on the anterior cervical lip. A portion of the tumour removed for diagnostic purposes showed in section the histological appearances of a gumma. At the post-mortem examination four weeks later the right tube and ovary were found in one gummatous mass and the entire surface of the endometrium was replaced by a similar mass several centimetres thick, penetrating deeply into the myometrium. Gummata were also present in the liver and in the lungs.

Portis recorded an interesting case showing very early secondary syphilitic changes in the uterus.

His patient, aged 38, was admitted for metrorrhagia. On examination the cervix was thickened and indurated, the surface being ulcerated and covered with a greyish exudate. The uterus was moderately enlarged. Carcinoma of the cervix was diagnosed and a panhysterectomy done. The patient made an uneventful recovery, but returned seven weeks later with an extensive secondary rash. The Wassermann reaction was strongly positive. Microscopical examination of the uterus showed signs of a healing chancre on the cervix. The endometrium was diffusely infiltrated with lymphocytes and plasma cells, and this infiltration extended throughout the thickness of the myometrium, being more marked just beneath the endometrium. The left ovary showed a corpus luteum extensively infiltrated by lymphocytes and plasma cells. Sections stained by the Levaditi method showed treponemata in the cervix and the myometrium, and an occasional one in the corpus luteum and the stroma of the left ovary.

Various authors have described cases of syphilitic fibrosis of the uterus. The majority based their diagnosis of the condition on the fact that menorrhagia had reacted to antisyphilitic treatment, when the Wassermann reaction had been positive. In those

few cases where the uterus was examined arteriosclerotic changes were noted. Some deny that this is evidence of a syphilitic infection, as they found similar changes in non-syphilitic uteri.

It is interesting to note that fibrosis can occur as a late result of the gummatous condition described in this paper, and that the latter is probably preceded by the secondary changes recorded by Portis.

I have to thank Miss Sylk and Miss E. H. Lepper for permission to publish the case.

A CASE OF STRANGULATED INGUINAL HERNIA IN AN INFANT AGED FOURTEEN DAYS.

By Maurice E. M. Jago, M.B., B.S. Lond.,
RESIDENT MEDICAL OFFICER, MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON.

THE following case is of interest on account of the rarity of strangulated hernia at so early an age.

The child was admitted into the Miller General Hospital on Dec. 7th, 1927, on account of vomiting and the passage of blood per rectum. It was one of twins aged 14 days and a swelling in the right inguinal region had been present since birth. Several other children in the family were likewise born with a "rupture." On Dec. 6th the parents thought the child did not seem well and on the 7th he vomited and seemed very ill. The bowels were opened before admission following the use of a soap suppository.

On admission the baby looked ill and somewhat undersized. The clothes were stained with vomit, which was fæculent in nature. Temperature 96° F.; pulse-rate, 116; respiration-rate, 44; weight, 4½ lb. In the right inguinal region was a swelling conforming more to the shape and feel of a hydrocele than to a hernia. On attempting to reduce the mass into the abdomen the baby cried violently and no decrease in size resulted, neither did it disappear when the infant was suspended by its heels. The abdomen was distended but fairly soft; visible peristalsis was seen, but no tumour could be palpated. Rectal examination revealed no tumour or emptiness in the right iliac fossa. There was blood on the examining finger and some fæces were passed.

As strangulated hernia is rare in an infant of this age there seemed some doubt as to whether the baby was suffering from an intussusception or whether the inguinal swelling was a strangulated hernia, but it was decided to explore the inguinal canal. The operation was performed under spinal anæsthesia with ½ c.cm. stovaine solution, and this successfully abolished the movements of the lower limbs. When an incision had been made over the right inguinal canal the mass was found to be a hernia. The sac was cleaned and opened and contained a portion of the ileum. The bowel was purple, but the peritoneal coat was shiny and it was evidently viable. Reduction could not be effected by taxis until the neck of the sac had been divided, following which procedure a part of the cæcum prolapsed. After reduction the neck of the sac was ligated and the conjoined tendon and the inguinal ligament approximated with sutures. The spermatic cord and accompanying structures were not defined during the operation.

The child made a good recovery and retained sterile water by mouth immediately, with no more vomiting. Breast feeding was impossible and citrated whole milk was given and received well except for constipation, which was relieved with saline wash-outs per rectum. Slight suppuration occurred in the wound which, however, healed in 12 days. The right testicle could not be palpated and its fate was uncertain; the left was normally descended. The baby gained weight steadily and weighed 4 lb. 14 oz. by Dec. 24th. He was discharged on Jan. 2nd, 1928.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DISEASE IN CHILDREN AND SECTION OF SURGERY.

A JOINT meeting of these Sections was held on Feb. 24th, Mr. G. E. Waugh, President of the Children's Section, in the chair, to discuss the subject of

CHRONIC APPENDICITIS IN CHILDREN.

Dr. Robert Hutchison began by considering the question whether chronic appendicitis really existed in children. He did not agree with a writer who stated that in the earlier years of life appendicitis was either acute or non-existent, for the occurrence of chronic appendicitis had been proved by exploration; nevertheless he believed that it was rare under 14 years of age. Another question was whether the chronic condition always arose out of an acute attack. If so it should be possible to learn of an illness which might have been acute appendicitis, but such a history could not always be obtained. There was the chance that an acute event had been passed over as of no consequence or had been mistakenly regarded as stomach trouble or a "bilious attack"; but, on the other hand there seemed to be no *a priori* reason why a primarily chronic inflammation of the appendix should not occur, just as tonsils might be chronically inflamed although there was no history of acute tonsillitis.

Granted the existence of chronic appendicitis in childhood, what were the symptoms and signs by which it could be recognised? In the adult appendicitis might simulate gastric disease, but he did not think "appendix dyspepsia" occurred in childhood in the young the condition was more apt to simulate an affection of the colon. In the clinical picture presented by chronic appendicitis in childhood the cardinal feature, in Dr. Hutchison's opinion, was recurrence of episodes of abdominal pain, either with or without vomiting and slight fever, lower abdominal pain being the most constant and important. Fever might be either slight or absent, and if the patient happened to be seen between attacks there might be no physical signs. If pressure over McBurney's point caused pain at that spot and there was no tenderness elsewhere, it was suggestive of appendicitis, especially if the pressure caused pain which was referred to the epigastrium; but this sign could be elicited with confidence in only a few children. Pain confined to the right iliac fossa he believed to be but rarely due to chronic appendicitis, but if the pain came on after exertion, rather than after a meal, it suggested appendicitis. If the patient happened to be seen during an attack the diagnosis became easier, as there should then be tenderness, perhaps rigidity, on palpating the right iliac fossa, though it must not be forgotten that these signs might be due to inflamed glands. Radiography, he thought, could not determine the diagnosis; indeed it might only add another element of doubt to an already doubtful situation.

Among the conditions which might simulate chronic appendicitis in childhood were: other organic conditions in the right iliac region, such as enlarged glands; kinking of ileum or appendix; a mobile cæcum; and an adherent Meckel's diverticulum. He did not think they could be reliably distinguished from chronic appendicitis, nor from one another except by exploration. Obstruction of ureter by stone should be detectable by radiography and by expert examination of the urinary passages and of the urine. Pelvic affections in girls could be diagnosed usually by bimanual examination per rectum, under anæsthesia if necessary. Ovarian pain at about puberty for which no organic basis could be found usually ceased with the regular onset of menstruation. Intestinal colic was very common in childhood, and was sometimes

accompanied by vomiting. Sometimes colonic pain could not be distinguished from that of appendicular origin. Often the pain was referred to the umbilicus and was for this reason sometimes called "umbilical colic." The more frequent the pain and the closer its onset was related to meals the less likely was it to be due to chronic appendicitis. But Dr. Hutchison thought a long and adherent appendix might play a part in disturbing the colon. Often, too, slight attacks of acute appendicitis were mistaken for "bilious attacks." Some surgeons appeared to think that cyclical vomiting could be cured by removal of the appendix. His own view was that true acidosis, with recurrent vomiting and perhaps fever, and the presence of acetone bodies in the urine, were of hepatic origin. These cases could be distinguished from acute appendicitis, too, by the great predominance of vomiting and by the comparative absence of pain. Still the same kind of child was subject to both conditions. In many cases the diagnosis of chronic appendicitis in the child was more or less conjectural. In his own practice, when everything discoverable seemed to point to chronic appendicitis, what he advised was not appendicectomy, but exploration of the right iliac region. He specially advised this if the child was being sent to school where surgical help would not be readily obtainable, if the parents were worried lest appendicitis should occur, and in cases in which there was a strong family history of the disease. In most of the explored cases appendicitis had not been the cause of the symptoms, but the surgeon had seldom drawn a blank; he often found a kink, or enlarged glands, or a constricting band.

Surgical Points of View.

Mr. A. J. WALTON said that in most cases of so-called chronic appendicitis there was an atonic condition of the cæcum associated with virginal ptosis. Of 906 cases of appendicitis uncomplicated by any other lesion, 601 were acute and 305 chronic. In this series 186 of the patients were under 14 years of age, but in only 33 was the condition chronic. The mortality of acute appendicitis in childhood was still too high. It was well known that it was difficult to obtain a complete history in the case of young children; therefore an account of any bout of severe pain and vomiting should be taken seriously, especially if followed by localised signs of appendicular trouble. In five of his cases the lesion found was a subacute or chronic inflammatory change in the mesenteric glands, especially those at the ileo-colic angle. In five cases of visceroptosis in girls aged 13 there had been frequent attacks of pain in the right iliac fossa and lower abdomen, but without the formation of an inflammatory mass. In four cases with symptoms suggestive of appendicitis threadworms were found in the lumen of the appendix. He had not met with any cases of appendicitis in children in which the condition had been chronic from the beginning.

Mr. H. W. CARSON said he had no doubt, from his own experience, that chronic appendicitis occurred in children, but there were important respects in which it differed from the same condition in the adult. He agreed with Dr. Hutchison that the so-called "appendix dyspepsia" did not occur in children, neither did they suffer from symptoms of visceroptosis, though they might be found to have a mobile cæcum. In children it was common to find the appendix in the "5 o'clock position"—a dangerous position, as the appendix was hanging over the pelvic brim. Threadworms in the appendix produced chronic appendicitis, rather than an acute perforative lesion. With regard to the presence of glands in the ileo-cæcal mesentery, he had concluded, as the result of a good deal of study, that these glands were not tuberculous at the outset; he believed that originally they were chronically inflamed, and that subsequently the tubercle bacillus found a congenial habitat in them, owing to their low resistance. He regarded infection of these glands in the mesentery not as a part of a systemic infection, but as a local one, probably due to ingestion of tuberculous milk. In the majority of cases he thought enlarged glands in this region could be differentiated clinically from appendicitis, and in making the diagnosis he laid most stress on the character of the attacks; though periods of pain might occur repeatedly, it was not continuous as it was in appendicitis. He agreed that in children the difficulty was to get an unequivocal history of acute attacks of appendicitis preceding the more chronic condition.

Doubts and Criticisms.

Dr. G. A. SUTHERLAND expressed himself as still uncertain whether chronic appendicitis existed in children, though admittedly if an attack of acute appendicitis had been skilfully treated by the physician adhesions might have formed and produced symptoms which some might term chronic appendicitis. That, however, was not what was usually understood by the term. He did not agree with Dr. Hutchison that a child should be operated upon because the parents were over-anxious about appendicitis, nor did he think there was evidence of appendicitis being a familial complaint. He would rather allow such a child to play about with other children and watch the result, as in doubtful cardiac disease, giving at the same time a full diet.

Mr. WARREN LOW hoped that Dr. Sutherland's ideas would not be accepted. He spoke of two members of a family of three dying of acute appendicitis, the third nearly succumbing to the same complaint. He had always felt convinced of the presence of chronic appendicitis in children. Some appendices, when exposed, were stiff and chronically inflamed; indeed they seemed to be almost composed of erectile tissue. He believed that chronic inflammation of the ileo-cæcal glands had a definite relationship to the state of the appendix.

Dr. A. CAWADIAS did not agree with the division of appendicitis into acute and chronic; he believed it made for clarity to speak of the acute stage as paroxysms of an otherwise chronic state of inflammation of the region. If such a conception were prevalent he thought there would be less temporising, which so often led to disaster. Still, there was little doubt that many unnecessary operations were carried out for the condition. Observation with the iridescent screen, combined with palpation of the appendix region—especially the point of its insertion—was a valuable aid to diagnosis.

Mr. L. E. BARRINGTON-WARD said that what Dr. Hutchison referred to as chronic appendicitis he personally preferred to regard as recurrent appendicitis. No sane surgeon would operate for acidosis under the belief that it was appendicitis. He did not think that visceroptosis was ever found in a child. He agreed that when there occurred chronic attacks of disease, such as several speakers had mentioned, exploration should be carried out.

Dr. A. G. MAITLAND-JONES declared himself also a sceptic on the subject of chronic appendicitis in childhood. He agreed with Dr. Hutchison that in some cases it was desirable to "treat" the parents, especially as an exploration might prevent a catastrophe.

Two Forms of Chronic Infection.

The CHAIRMAN pointed out that when examining the abdomen of a child who was not suffering from acute appendicitis it was impossible to predict what was the intimate cell structure of the particular appendix. The pathologist would in many cases say, on its removal, that there was no evidence of inflammation, but he supplied no test which allowed the clinician to decide on the nature of the condition present. Mr. Waugh drew special attention to two types of chronic inflammation. One was a primary tuberculous infection of the appendix, which, in his experience, was more common when the appendix was in a hernial sac than when it was in the abdomen. It attracted attention by the intensity of the pain, unassociated with toxæmia, and if there was no spread by miliary tuberculosis to other parts of the

peritoneum, the condition could be cured by removing the grossly tuberculous appendix. The other condition was invasion of the appendix by streptothrix, and this constituted one of the most disastrous traps to be met with, as there were no abnormal signs suggestive of primary abdominal disease. The evening temperature might reach 106° F., dropping in the morning to 99°, the only accompaniment being a vague abdominal discomfort, and after several weeks a small circumscribed tender swelling appeared, giving an impression that the appendix was encapsuled. A few days after removal of the appendix, however, the patient seemed worse, and a glistening substance might be observed in the affected area, as if a snail had crawled over it.

Replies.

Dr. HUTCHISON said he was prepared to accept Dr. Cawadias's definition of so-called chronic appendicitis. With regard to observation with the iridescent screen he still felt it must be difficult to distinguish a tenderness which was due to glands from that due to the appendix itself. He did not think that even the leucocyte count would make diagnosis certain. He certainly did not agree with Dr. Sutherland that in doubtful cases one should get the child up and out of bed, to see what happened; what might happen was perforation of a gangrenous appendix. The heart did not furnish a parallel case, for a heart had great power of recovery if tried a little too far. To explore the appendicular region in the doubtful cases in which the parents were very anxious was not only of benefit to the parents, but also had a good reaction through them on the child.

Mr. WALTON said he had not seen threadworms in acute attacks; usually they were harmless passengers, but in the cases he had mentioned the symptoms cleared up after removal of the appendix. Often, he agreed, enlarged ileo-cæcal glands were not primarily tuberculous. Adhesions which formed after operation for appendicitis showed a natural tendency to disappear later.

SECTION OF EPIDEMIOLOGY.

A MEETING of this Section was held on Feb. 24th, with Dr. L. S. MONCKTON COPEMAN, the President, in the chair, when Dr. REGINALD MILLER read a paper on

SOME PUBLIC HEALTH ASPECTS OF JUVÉNILE RHEUMATISM.

The incidence of heart disease showed, he said, that rheumatism occurred in 1·5 to 2 per cent. of urban elementary school-children. Its depredations were best studied in this class, but there were two difficulties in estimating its amount. First, heart disease was much commoner in school "leavers" than in school "entrants," and, secondly, the disease was more common in urban than in rural children. Probably the figure for entrants was about 1 per cent., and for leavers between 2 and 2·5 per cent. There was little evidence of the incidence in secondary schools, but at the Polytechnic School in Regent-street 1·53 per cent. of the 600 boys showed rheumatic heart disease in the years 1924–26. An interesting fact was that of the fee-paying boys only 0·98 per cent. had cardiac trouble, while the figure was 2·57 per cent. for those entering with scholarships from elementary schools. It was difficult to estimate what proportion of the 60,000 deaths annually attributed to heart disease were really due to rheumatism. In hospitals the proportion was about 50 per cent., but Dr. Miller thought it safer to put the figure at 20,000. Coombs had estimated that about five years of increasing invalidity preceded every death. Under the age of 2 rheumatism was practically unknown; from 2 to 5 it was uncommon, and the maximum incidence occurred between 7 and 8. At puberty the disease began to change to the adult type. The factors governing the age-incidence were, in Dr. Miller's opinion, chronic tonsillar infection, the less protected régime of school life, and childhood's diminished resistance to infection. The upper limit of the class incidence was well seen in the absence of the disease from private schools and its rarity in private practice. The lower limit was less definite but very interesting; the real rheumatic stratum lay in the upper section of the poor. The class incidence showed that the onset of the disease was not entirely governed by overcrowding, underfeeding, dirt, or the other accompaniments of semi-destitution. Clinical workers were convinced that the disease did not spread from case to case.

The Environmental Factor.

When London poor children were taken away from home and put in country residential schools rheumatism was unknown among them. This fact urgently needed explanation. Inheritance, at the most could only aid and abet environment. The special factor, the speaker believed, was damp dwellings. Damp predisposed to catarrhal colds and so might affect the tonsils. The disease was commonest in cold, damp countries, and the sites of the homes of rheumatic children tended to be on low-lying areas and to follow water-courses. Recent investigations had shown that about 60 per cent. of rheumatic children were living in obviously damp rooms. The proportion of a series of non-rheumatic families living in damp rooms was only 30 per cent. It was the condition of the house rather than of the site that was important; rheumatic and non-rheumatic areas might lie side by side. In Eton town there was plenty of juvenile rheumatism; in Eton College none. This factor explained why the poorest people of all suffered less, for overcrowding meant more warmth and less damp. Notification was worthwhile, as it gave a keen medical officer of health the chance to deal with unhealthy houses. An urgently needed reform was adequate warming and drying of children who arrived at school wet. School "inspections" must be turned into examinations, but treatment should be left to practitioners and hospitals.

Dr. J. TERTIUS CLARKE read a paper on the

PATHOGENESIS OF RHEUMATIC FEVER IN ITS CLIMATOLOGICAL RELATIONSHIP TO A POSSIBLE INSECT CARRIER.

He pointed out that during more than 30 years' service in the Malay Peninsula he had not seen a single case of rheumatic fever, chorea, or subcutaneous nodes. Inflamed tonsils were as common in the tropics as in England. The very few cases reported from the tropics were not true rheumatic fever. The common rat flea, *Ceratophyllus fasciatus*, had also not been found in the tropics, its upper temperature limit lying at about 70° F. It flourished in a humidity of 70 per cent. The environmental conditions favouring the fever also favoured the rat flea. The evidence that a bacillus caused rheumatic fever was not convincing, and he suggested that the disease might be due to a protozoon carried by the rat flea. Protozoa-like rheumatic fever but unlike bacilli, were unevenly distributed over the world, and the lesions of the disease were formative and proliferative rather than exudative. The slight leucocytosis of the fever was mononuclear.

The Case against the Dampness Factor.

The PRESIDENT said he had seen in country villages conditions of dampness far worse than anything in towns, and he felt that Dr. Miller's suggestion required further investigation.

Dr. J. A. GLOVER said that he feared Dr. Miller's arguments were not so watertight as the houses he would like to see. He thought that the placing of highest incidence in the upper stratum of the poor was due to the fact that the principal investigator had worked in the more prosperous parts of the town. The figures published in the Medical Research Council's report showed that the difference between the poor and the very poor was not great enough to be significant, and what evidence there was went the other way. Moreover, the really destitute mother would not take her children to clinics; she waited

till they were really ill and then took them to the infirmary. He showed a table of the children in the infirmaries of London; Poplar had 98 children under 15 suffering from acute rheumatism, and Marylebone only 10. The work of Carsdale in the Isle of Dogs and Homerton in 1911 had shown that an enormous proportion of really destitute children were rheumatic, and workers in New York had pointed out the marked effect of malnutrition. Familial incidence had been strikingly brought out by the researches of Mrs. Forest Smith. The high rate at the Royal Naval School at Greenwich (S. F. Dudley) showed the ill-effects of overcrowding on picked boys. The map published by Dr. Matthew Young showed that the mortality-rate was lowest of all in the Ouse and Cam valleys, where sanitary authorities were backward, and there were plenty of damp houses on damp sites.

Dr. F. C. SHRUBSALL described work done by his wife, showing a very definite association between rheumatism and water-courses. Aliens had been found to be much less affected in the same areas. The worst houses were always in the valleys, and it might be that new houses were damper in themselves. Where an old area had been cleared and rebuilt, as in the Wandle valley, there was high incidence. He pointed out that the school medical inspection was no procession past a point, but a thorough investigation.

Dr. J. NAIRN DOBBIE also described the carefulness of the examination and after-care of school-children. Of 100 cases he was analysing 35 came from very poor slums and 60 from very poor homes verging on the slum type. Rheumatism, in Dr. Dobbie's opinion, was essentially a poverty disease, and reflected the degree of poverty to a very great extent. Sixty-six per cent. of his cases showed a clear and immediate family history of rheumatism, and in a further 11 per cent. the disease appeared in the immediate collaterals. Although environment was the immediate cause there was a definite diathetic factor. The tonsils were defective in 80 per cent. of cases, but in no case was the child of the typical adenoid type, and it was not the catarrhal child who developed rheumatism, but the nervous, highly strung, psychasthenic type. The future of school medicine lay in the improvement of environment at the "pre-school" stage, between the ages of 2 and 5, as many of the children entering school at 5 were recognisably "pre-rheumatic."

Dr. WARREN CROWE suggested that rheumatic infection might be conveyed by the immune adult to the susceptible child through the nurse's habit of tasting food from the child's spoon.

Dr. DAVID NABARRO suggested that information might be gained by following up for several years the children whose tonsils had been removed at hospitals, and that it would be worth while to test the biochemical reactions of the tissues of the rheumatic child and his brothers and sisters and see if they differed from those of the non-rheumatic child.

Dr. MILLER, in reply, said that statistics of rural children were so inadequate as to be unreliable. Dr. Dobbie's figures proved nothing but that a large number of very poor children suffered from rheumatism. The only really satisfactory test was the geographical one, over a circumscribed area in one district. This had only been applied by Mrs. Shrubsall and in Birmingham, and both researches had shown that rheumatic and poverty areas did not properly correspond. He begged the public health authorities to bridge the great gulf between clinical and bureaucratic medicine and to build upon the foundations laid by clinicians in this matter, and not start de novo and waste years of work.

Dr. CLARKE, in reply, said that practically every environmental factor mentioned that evening was common to the rat flea and to rheumatism. The rats lived along rivers and in crowded residences. The rat flea was rife in Lancashire and Yorkshire, and very rare in the Eastern counties.

MEDICO-LEGAL SOCIETY.

DISCUSSION ON THE INFLUENCE OF PARTURITION UPON INSANITY AND CRIME.

A MEETING of this Society was held on Feb. 23rd with Sir WILLIAM WILLCOX, the President, in the chair, when Prof. LOUISE MCILROY read a paper on this subject, which we published in full last week, p. 379. A long discussion followed.

Mr. Justice HUMPHREYS said that the best answer to the critics was that no jury in this country had ever yet convicted a woman in the circumstances suggested by Prof. McIlroy. The verdict "Guilty but insane" amounted in law to one of "Not guilty, but the prisoner should be detained until His Majesty's pleasure is known." English law would never be logical, but the English people had an extraordinary capacity for doing justice by perhaps illogical means, and the practice of leaving the question of insanity to the jury did in fact result in justice being done. The rules in McNaghten's case were not particularly logical, and might admit of amendment, but the speaker doubted very much whether they acted unjustly on persons who had committed crimes when insane and therefore not responsible. It was important not to include in Acts of Parliament anything that might help the criminal to escape. Juries tended perfectly naturally to take advantage of any circumstance that might enable them to acquit when the penalty was a very serious one, and they should not be assisted to go wrong in this direction. This was the difficulty in the way of altering the language of the Infanticide Act in the direction suggested. The Act was probably unnecessary, except to prevent the horrible farce of a judge assuming the black cap and sentencing to death a person who, as he and everyone else knew, was not in the least danger of being hanged and who would probably be released in a few weeks. If, however, the Act was to remain, there should be a definition in the next Act of what was meant by "newly born." It might be possible to omit the phrase altogether and leave the question of responsibility to the jury; the only objection the speaker saw to this was that it might encourage the type of medical witness who was always prepared to come forward and swear that the accused was suffering from whatever disease would entitle him or her to acquittal. In answer to a comment by Lord Riddell, Mr. Justice Humphreys explained that the House of Lords had explained that the prisoner, found "Guilty but insane," was found guilty of having done the act which in a sane person would amount to the crime with which he was charged, but not guilty of having committed any crime. The difficulty lay in the fact that there was no adjective in the language which would convey this precise meaning.

Lord RIDDELL said that the man in the street regarded a verdict of "Guilty but insane" as a verdict of "Guilty of murder but insane," a mistake that would be avoided if the law were altered as the learned judge and Prof. McIlroy had suggested. As he understood the law, it was the duty of a judge, when a delusion or "irresistible impulse" was pleaded and the facts were proved, to direct the jury to return a verdict of guilty. This Act had been admitted to Parliament in a most perplexing form. An amending Bill in the form suggested would be very useful and a great relief to lawyers, who now had to enforce a law which was understood by no one.

Dr. F. J. MCCANN suggested that "newly born" should mean not more than 24 hours old. In the first 24 hours an unmarried woman might temporarily lose her reason through the agony of despair. It was at that time that animals ate their young, but later on the condition of affairs was quite different. Unless this limit were imposed, some medical men would always be ready to swear that a woman's crime was

due to her confinement—even two years afterwards. In a sense some women never recovered from confinement. There was no essential difference between the stress of lactation and any other stress that might cause insanity. This limit would distinguish the particular type of case from the remainder, which were adequately dealt with by the law relating to insanity. Steps should be taken to ensure adequate legal defence for poor prisoners charged under this Act, and expert post-mortem examination of the corpse of the child. To send organs or parts of organs did not give pathologists a fair chance.

Dr. C. HUBERT BOND foresaw confusion of the issue by the nomenclature suggested. Such terms as puerperal and lactational insanity were misleading. Another source of confusion lay in using such terms as "insanity," "psychosis," "mental disorder," "abnormal mental state," and "disturbed balance of the mind" without being sure how far, if at all, they were intended to be synonymous. Precision here was of vital importance if the two professions were ever to reach mutual understanding or agreement. The McNaghten rules were beside the point in a discussion on the Infanticide Act. A woman might be punished as guilty of manslaughter when, but for the Act, she would have been found guilty of murder; she became a murderess in the eye of the law and could not be sent to an asylum. In passing, Dr. Bond registered a caveat against regarding detention in Broadmoor as either being or intended to be a punishment, and against the use of the word "incarcerated" in referring to any institution for mental cases. The Infanticide Act, he said, absolved the court from an unpleasant duty, but did not absolve the woman from more than the ordeal of hearing herself sentenced to be hanged; it stigmatised and punished her as a felon. There would be no need, either biological or sentimental, for the Act if we could get rid of the McNaghten rules and of the tendency to regard the evidence of all medical practitioners, expert in psychology or not, as of equal weight. By providing the court with an escape from a false position the Act had delayed still further the attainment of unity of thought on these matters. The necessity for its improvement was obvious. The use of the undefined phrase "newly born" was particularly illogical and short-sighted. The woman might, in that abnormal mental state, kill an older child, or the child of other parents whom she had befriended.

Dr. J. S. FAIRBAIRN said that crimes committed in a state of puerperal and lactational insanity should be looked on from a totally different aspect from those due to the actual stress of delivery. The time during which the stress of parturition might lead to crime was a matter of days only, and the woman who was insane was already protected. In considering how long delivery should be a factor one had to recognise the enormous difference in the temperament, constitution, and circumstances of individual women. A week or ten days might be regarded as a fair period.

Sir HERBERT AUSTIN said that the case of Mary Donoghue had nothing to do with the Infanticide Act. She had been discharged from the infirmary completely cured and had gone back to her regular work; the crime had had nothing to do with her condition. The verdict of "Guilty but insane" was not a verdict of "guilty," and there was no appeal against it. In support of confidence in the jury's discretion he mentioned the case of a woman who had been tried twice on the charge of child murder and found guilty but insane by reason of her confinement. The question of the defence of a poor prisoner might be left quite safely to the presiding judge.

Dr. HALLIDAY SUTHERLAND pressed for the deletion of the term "newly born." If the woman were insane, the provisions of the McNaghten ruling covered her case completely. He objected to the verdict "Guilty but insane." Murder was still, in Lord Coke's terms, "with malice aforethought taking the life of a reasonable creature in being," and of that the prisoner was convicted. To be logical the verdict should be "Not guilty but insane, and therefore worthy of detention." He understood that the form of the verdict was due to Queen Victoria, who had been unable to understand how any person who threatened Her Majesty's life could be "Not guilty."

Dr. MORGAN FINUCANE objected to the verdict because it resulted in women who were not responsible for their acts being shut up in Broadmoor. He pointed out that childbirth of itself imposed a strain much greater than any other crisis, and was likely to lead to abnormal conduct quite apart from puerperal insanity.

Dr. GRAHAM GRANT gave an example to prove that patients were released from Broadmoor as from other mental hospitals as soon as they were fit to be at liberty.

Dr. NORWOOD EAST agreed that, although the law was illogical, in practice justice was done. Fatherhood equally with motherhood was a necessity for the race, and fathers were sometimes tried for killing their children and found insane. One of the contributing factors in such a case was the stress of providing for their families, and it would be difficult for juries to draw a distinction between motherhood and fatherhood.

Mrs. MARIE STOPES said that the various attempts to define "newly born" were illogical unless they limited it strictly to 24 hours, which seemed harsh and out of the spirit of the Act. Since the distress and strain were apt to persist after the mother was up and about, she would like to suggest that the Act should extend until the child was weaned.

Dr. H. R. OSWALD agreed that there was no need for the term "newly born"; any interpretation beyond 24 or 48 hours made the word absurd.

Dr. REGINALD WORTH said that in his experience 75 per cent. of the women committed to Broadmoor for killing their children had done so during the lactation period, and that insanity occurring after childbirth was equally divided between the puerperium and lactation. If a woman killed her child during either period her confinement must have been a contributing cause. The emotions that a woman suffered during gestation could not be eliminated in a few hours. The period should extend until the child was weaned, and, since the mere fact of a mother, with her maternal instincts, killing her child showed that she was insane, it should be for the prosecution to prove to the contrary.

Prof. MCILROY, in reply, amplified Dr. Finucane's plea for the mother. Childbirth was so great an ordeal, even to the most normal woman, that its effects on the mind could not be classed with any other form of mental disorder. She read the following extract from a letter from Lord Justice Atkin, to whom she had sent a copy of her paper:—

"I agree with you that either the expression 'newly born' should be defined in time or the protection to the mother should extend as long as (perhaps within a time limit) she has not fully recovered and the balance of her mind is still disturbed. But this does not really affect the question of puerperal insanity unless the second alteration above is adopted and made wide enough. The kind of case you have in mind is exactly the class of case our committee were thinking of when we suggested an amendment to the law of criminal insanity of wholly uncontrollable impulse due to mental disease. The latter qualification would denote what you call insanity. The only criticism I have to make on your paper is that you seem to accept the Lord Chief Justice's criticism on this as possibly just, and then go on to prove that it isn't. The answer that may be made is that in practice, whatever the rules in the McNaghten case say, a woman such as you describe would be found guilty but insane. I think you may take it that this is generally true. Your juries and judges are often more humane than loyal, but it has always seemed to me to be a reproach to the law that it can ever be reasonable in practice only by being violated in theory. I hope in reply you can emphasise what you say in your paper that in the case you refer to the woman knows what she is doing and knows that it is wrong but (*a*) does the act from an impulse which she cannot at all resist, and (*b*) is at the time insane or suffering from mental disease."

HUNTERIAN SOCIETY.

At a meeting of this Society held on Feb. 27th, Mr. A. MORTIMER WOOLF, the President, being in the chair, Dr. ANTHONY FEILING delivered the Hunterian Oration on

SCIATICA: ITS VARIETIES AND TREATMENT,

a subject which was justified, he said, by the aggregate of suffering and disability lost through this common disorder. Unfortunately the term had been accepted by the public to designate almost any kind of pain in the region of the lumbar spine, buttock, hip, or leg, but sciatica should be thought of as merely signifying pain in the distribution of the sciatic nerve. It was convenient to speak of a secondary or symptomatic sciatica due to some gross pressure lesion and a primary or essential sciatica the exact ætiology of which was a matter of doubt and dispute. The part played by the fifth lumbar nerve in the production of symptoms was clinically important and was accounted for in part by its long oblique course to the plexus.

Secondary Sciaticas.

Secondary sciatica might be due to many lesions, including tumours of the rectum, pelvic organs, pelvic bones, or vertebral column; disease of the hip-joint, sacro-iliac joint, or joints of the lumbar spine; affections of the roots of the cauda equina, such as syphilitic inflammation; and the effects of old injuries and disease of the spinal cord—for instance, tabes. Physical examination must in all cases include the vertebral column, hip-joint, abdomen, nervous system, rectum, and sometimes pelvis. Gross pressure lesions were not common, but osteo-arthritis of the hip was often overlooked. Careful passive movement should not produce pain in the hip in true sciatica, nor should there be any real limitation of movement. Radiography was essential. The following symptoms should at once seriously invalidate a diagnosis of primary sciatica: pain extending to the anterior aspect of the thigh, perineum, groin, genital organs, abdomen, or abdominal wall; motor paralysis of leg or thigh or a dropped foot; loss of knee-jerk; marked muscular atrophy; reaction of degeneration in any muscles; severe vaso-motor disorders, œdema, or trophic ulceration; interference with the nervous control of micturition, defæcation or the sexual functions; lordosis or gross deficiency in the movements of the spine; and, finally, the history of an operation for malignant disease. Bilateral pain should excite grave suspicion, but it was possible for an essential sciatica to affect both sides.

Primary or Essential Sciatica.

Primary sciaticas were usefully divided into two groups: those where the symptoms suggested a true neuritis and those where the trouble seemed to lie in the region of the lumbo-sacral vertebræ. The true neuritis was an interstitial neuritis or perineuritis, and its precise ætiology was generally uncertain. This form occurred frequently in diabetic subjects. It was a good practice to seek and remove foci of sepsis, but the speaker confessed to little success from this line of treatment. The sensory functions were affected almost exclusively, presenting a strong contrast to the effect of pressure, where early sensory symptoms were soon followed by motor disturbances. Except in very severe or long-standing cases muscular wasting in primary sciatica was very slight and more or less global (i.e., affecting all the muscles of the limb equally). Kernig's sign would cause pain in many conditions where the nerve or its roots were affected by pressure or inflammation. The simplest test for real neuritis was tenderness on direct pressure, most easily elicited over the sacrosciatic notch and midway between the tuber ischii and the great trochanter. Sometimes it was also found in the popliteal space and over the external popliteal nerve at the head of the fibula. Mere discomfort was insufficient for diagnosis; the pain elicited must be acute. Another almost invariable sign of real neuritis was the disappearance of the ankle or Achilles jerk, often associated with exaggeration of the knee-jerk. The ankle-jerk might never return after an attack.

Juxta-vertebral Sciatica.

When secondary sciatica and true neuritis had been excluded there remained a large number of cases of uncertain nature, with practically no tenderness of the nerve and sometimes without loss of ankle-jerk. The pain tended to radiate, especially in the area of the fifth lumbar root; it was uncommon to find it on the sole or calf. The lesion was probably vertebral or juxta-vertebral. Scoliosis was often associated with sciatica, especially with the obstinate and chronic cases, and was most commonly of the contralateral type. With it were found rigidity of the lumbar spine, defective movements in all directions, and often a firm contracted condition of the erector spinæ. This form of scoliosis was due to a muscular reflex contraction, tending to produce enlargement of the intervertebral foramina on the side of the sciatic pain. When the scoliosis was homolateral, lessening tension on the nerve of that side, it was cured by saline injection into the nerve, suggesting that the lesion was probably a neuritis of the sciatic trunk. Much less common was an alternating form of scoliosis, believed by Putti to be due to bilateral arthritis of the lumbo-sacral joints, with need to rest first one side and then the other. Sicard classified neuralgic pains as due to lesions of the posterior root within the theca—"radiculitis," or between the ganglion and the origin of the nerve plexus—"funiculitis," or of the nerve plexus or trunk. Since funiculitis occurred in the intervertebral foramen, Sicard had coined the term "névrodocite" or "neurodocitis" of it. Apart from syphilis, herpes zoster, and spinal meningitis, the lesion within the subarachnoid space was not common. A unilateral neuralgia was more likely to be a funiculitis than a radiculitis, and in the latter a lymphocytosis of the cerebro-spinal fluid was found, while in the former there was a characteristic increase in protein without any increase in cells. This increase might be as much as 0·1 per cent. in sciatica. Putti [1] had made a useful distinction between "central" and "peripheral" sciaticas, the former due to vertebral lesions and the latter to neuritis or perineuritis.

Why is Sciatica Common?

The anatomical peculiarities of the lower lumbar region accounted for the frequency of "central" sciaticas. The last two lumbar intervertebral foramina were the smallest in the body and the fifth lumbar was peculiarly liable to congenital variations which might alter the size of the intervertebral foramen; it was, moreover, the "foundation stone" of the whole spinal column. Dr. Feiling had been unable to confirm Putti's statement that a spinal arthritis could always be demonstrated radiographically in central sciaticas. Even, however, when the sciatica had been ascribed to a lesion of the root or roots in the intervertebral canal the discovery of a cause for this arthritis was often hard. Foci of infection must be sought, and the possibility of an old gonococcal infection must not be forgotten.

Sacro-iliac Strain.

Dr. Feiling believed that disease of the sacro-iliac joint was a rare cause of sciatica, although minor inflammatory infections would be very difficult to detect. Hoyt Cox had distinguished two types of sacro-iliac subluxation, a traumatic and a postural form. In the second type, he maintained, sciatic pains were likely to be present, associated with undue prominence of the sacrum, rigidity of the spinal muscles, obliteration of the normal lumbar curve, lateral curvature of the spine away from the affected side, and marked tenderness on pressure over the joint. Trauma was not, however, confined to the sacro-iliac joint, said Dr. Feiling, and might well affect the lumbo-sacral spine and cause sciatic pain.

[1] THE LANCET, 1927, i., 53.

Muscular and ligamentous injuries might produce scar tissue with implication of nerve-fibres.

Treatment.

The treatment of the secondary forms was clearly that of the causal factor. In cases of neuritis or perineuritis rest in bed was nearly always essential, but splinting could seldom be tolerated. Heat was undoubtedly the best local palliative, whether achieved by poultice, fomentation, radiant heat, or diathermy. Ultra-violet rays were also useful. He had been little impressed by electricity. Milder cases might benefit from counter-irritation by liniments, ointments, or blisters, or by painting with strong hydrochloric acid. In the early stages of an acute neuritis massage was definitely contra-indicated. Innumerable drugs had been used, either as "cures" or to relieve pain. Any amenable condition, such as constipation or urinary infection, which might be a factor in causation, must be promptly treated. Salicylates and iodides had direct effect, but the intravenous injection of sodium iodide had no advantage over oral administration. Of analgesics dialacetin and allonal were of value, and particularly useful was a cachet containing aspirin grs. v., pyramidon, or amidopyrin, grs. v., and heroin, gr. $\frac{1}{4}$ or $\frac{1}{8}$. In really bad cases the temporary use of morphia was almost imperative. Cases of sciatic neuritis which did not yield in two or three weeks might be treated with saline injection into the nerve trunk; about 100 c.cm. should be used and the temporary pain controlled by a quarter of a grain of morphia. Injection of oxygen was also of value. Stretching the nerve by forcible manipulation was probably not of much use; in a very few highly intractable cases it might be justifiable to cut down on the nerve and freely incise its sheath longitudinally.

Great temporary relief in central sciatica might be obtained from epidural injection through the sacro-coccygeal foramen. Normal saline, novocain, or 10–20 c.cm. of a 40 per cent. solution of antipyrin might be used. This procedure, coupled with local application of heat, usually relieved most cases. Foci of infection must be treated and protein shock therapy had value. Putti was strongly convinced of the importance of immobilisation by a plaster jacket, later replaced by a celluloid corset, which was worn for 6 or 12 months. In chronic cases careful manipulation under an anæsthetic often gave relief.

EDINBURGH OBSTETRICAL SOCIETY.

A MEETING of this Society, with Dr. HAIG FERGUSON, the President, in the chair, was held on Feb. 8th, when Dr. D. M. LINDSAY (Glasgow) read a paper on the

Reduction of Forceps Delivery as a Basis for Prophylactic Gynæcology.

Internatal trauma affecting the birth canal was, he suggested, often due to the application of forceps; it might be visible to the naked eye or might be almost microscopical, and it was commonly a result of over-stretching of the paracervical tissue or pubocervical fascia. Antenatal supervision should minimise the number of forceps cases, and in his opinion only those in which there was a medium amount of overlapping of the fœtal head at the beginning of labour would require forceps delivery. Use of the forceps would also be advisable in cases of occipito-posterior presentation in which manual rotation was impossible, and in those difficult cases in which there was resistance of the pelvic floor and marked narrowing or tenseness of the vaginal introitus. Dr. Lindsay believed that the standard indications for forceps delivery could be very much reduced in number; he did not think, for example, that the use of forceps was warranted in cardiac cases, in which Cæsarean section was much more satisfactory. Fœtal signs of distress were certainly definite indications for interference, but such interference was only permissible when the labour had progressed far enough to make delivery safe for the mother; he saw no benefit in delivering a debilitated child quickly when rapid delivery entailed maternal injury. The mother's safety should be the first consideration. In the treatment of primary uterine inertia Dr. Lindsay was opposed to the use of forceps as delivery could often be effected by emptying the bowel and the bladder and by hot vaginal douching. In secondary uterine inertia the uterus required rest; morphia was indicated in such cases and no forceps. Perineal rigidity might be treated by the administration of light anæsthesia, and in persistent rigidity such anæsthesia, and such expedients as fundal pressure or administration of pituitary extract often gave the necessary stimulus. Where forceps were necessary they should be applied in such a way as to prevent serious birth injuries, and it had been proved that they were only safe when applied in the biparietal diameters. He regarded the axis-traction forceps as dangerous, for when they were applied with the head in the oblique diameter of the pelvis the vagina was pulled taut and forcibly twisted as rotation of the head progressed. This often caused extensive vaginal lacerations. In Dr. Lindsay's opinion the best instrument to-day was the Kiellan forceps. This was a long forceps, practically straight, the pelvic curve being almost negligible. Its application was always a biparietal cephalic one, no matter what the position of the head. It was smaller than the Milne-Murray forceps, it had no fixation screw and no axis-traction apparatus, and it was constantly under the control of the operator, who knew the amount of force being expended. There was much less compression of the child's head and (what was even more important) compression was always maintained in the safest cephalic diameters. If the high forceps operation was to remain at all in obstetric practice then the Kielland forceps was the ideal instrument. In conclusion, Dr. Lindsay condemned the use of forceps as a lever and as a rotator, stating that it should only be used as a tractor and considered as a compressor, the latter action being only utilised in the planes where it would be most efficient and where the compression would least damage the child. If this line of practice were followed it would be realised that the only safe forceps delivery which could be completed under the unfavourable surgical circumstances usually found in working-class areas was the low forceps operation.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 54 cases were considered and £957 voted 49 applicants. The following are notes of some of the cases relieved.

Daughter, aged 67, of M.R.C.S. Eng. who died in 1895. She has been mentally afflicted since childhood. Lives with a sister aged 61, to whom the Fund gave a grant of £26 in December. An old lady lives with them and pays 10*s.* a week. Income of sisters £34 per annum each. The cottage belongs to them and rates amount to £2 4*s.* 8*d.* per annum. Voted £26.

Daughter, aged 44, of M.D. who died in 1908. Her father lost all his money in speculation, and applicant, though delicate, trained as a nurse, which profession she followed until she had a serious breakdown through war work. She has several times tried to resume work, but the doctor now says she will not be able to do so again. She is suffering from tuberculosis. Own income £40. Lives chiefly with friends. Voted £26.

Widow, aged 65, of M.R.C.S. Eng. who died in 1903. Applicant and her daughter lived together until the daughter, aged 21, was removed to a mental hospital; her income of £70 per annum has now to be used for her maintenance in the hospital. This leaves the applicant with only £26 per annum allowance from her sister-in-law who also pays the rent. Voted £26.

L.R.C.P. & S. 1883, aged 73, married, wife, aged 74. They one son, who is married and has one child, has started a small preparatory school. Applicant, who had to give up his practice two years ago on account of deafness, says, "I have outlived and exhausted my little capital." The friends with whom he and his wife live cannot afford to keep them for nothing. Own income old age pension £52 per annum. Voted £40.

L.R.C.P. & S., aged 92, widower. As a result of losing all his money had to start again to practise, and last year made £173. He is really too old to work now, but force of circumstances renders it necessary. He received gifts to the amount of £25. Interest on mortgages £68. Rates, &c., £23. Debts £61. Voted £40 in quarterly instalments and a special grant of £15.

Subscriptions may be sent to the hon. treasurer, Charters Symonds, at 11, Chandos-street, Cavendish-square, W. 1.

Reviews and Notices of Books.

ACTINOTHERAPY.

Handbuch der Lichttherapie. Edited by W. HAUSMANN and R. VOLK, with the coöperation of O. BERNHARD, O. CHIEVITZ, F. M. EXNER, F. HAUER, K. HULDSCHINSKY, E. LANG, A. LAQUEUR, G. POLITZER, L. SCHÖNBAUER, J. SORGO, O. STRANDBERG, J. URBANEK, C. H. WÜRTZEN. Vienna: Julius Springer. 1927. Pp. 444. M.36.

THIS book presents in easily accessible form the work of some of the best-known continental authorities on actinotherapy. Since it is not a text-book on light treatment but a collection of valuable individual contributions, some repetitions and some contradictory statements are to be found. The section on light physics, energy measurements, and the discussion on recent work with photochemical and photoelectric methods will be helpful to those who are not familiar with this side of the subject. The biophysiological exposition is undertaken by Hausmann. Due stress is laid on the changes in the physical condition of irradiated proteins. In the section on metabolism, the point is made that although no change in total metabolism may occur, yet the study of the end-products of purin-metabolism shows that irradiation may influence some of the intermediate steps in the metabolism of animals. The diminution in blood-sugar and glycosuria in irradiated experimental animals and in diabetics is noted. In the pathological section some excellent micrephotographs are reproduced showing the changes observable in irradiated skin. Strandberg contributes two chapters, one on general indications for light treatment and one on the treatment of laryngeal, nasal, and aural tuberculosis. The good results obtained by this pioneer worker in tuberculous laryngitis by general carbon-arc baths, sometimes combined with carefully timed local interference, are now generally accepted. Bernhard, whose work is also known to English readers, reviews in the chapter on light treatment in surgery the results obtained by heliotherapy in the High Alps. Chievitz writes on the same subject, and it is interesting to compare his results, obtained by actinotherapy in Copenhagen, with those of the previous writer. Huldschinsky appropriately contributes the chapter on light treatment in pædiatrics. He considers prophylactic irradiations of all infants an ideal which has so far received too little support from local health authorities. One of the most valuable contributions is that of Sorgo, who supplies a considered statement of the probable mode of action of light treatment in phthisis. He makes evident the analogy with tuberculin and with non-specific protein therapy, and explains in a convincing way the apparently contradictory results and statements on the subject. Absorption from the irradiated skin of a substance which appears to be specific, and which causes focal reactions, is regarded by him as one of the main factors in the light treatment of pulmonary tuberculosis. Urbanek writes on the treatment of diseases of the eye. This is a field which has not yet been fully investigated and his article forms a good introduction to the subject.

Altogether a most informative collection of articles.

Actinotherapy for General Practitioners. By H. G. FALKNER, L.R.C.S., L.R.C.P. Irel., L.M.Rot. Dub., Actinotherapeutist to the London Teachers' Association; late O.C. Maudsley Neurological Hospital, Denmark Hill; late Medical Officer of Health, Lynton and District (Devon). London: Baillière, Tindall and Cox. 1927. Pp. 152. 7*s.* 6*d.*

THIS book, the author tells us, has been written at the request of many of his friends and particularly those in the medical profession who, desiring more practical knowledge of the subject, were unable to obtain any book dealing with it in a concise practical manner. Considering the number of books which have been published within the last three years on the subject of actinotherapy, we should not have thought that knowledge would have been sought in vain. Dr. Falkner's book is one which may be useful to general practitioners, but he is not always explicit in his statements, as for example, on p. 79, we read "It can be safely said that all cases of rheumatism, acute and chronic, neuritis, sciatica, &c., will be benefited if not cured . . . . One often encounters a patient whom the ray does not benefit." The book closes with a summary of diseases which, in the author's opinion, are suitable for actinotherapy, and the appropriate dosage is suggested.

HANDBOOK OF DISEASES OF THE EAR.

Fifth edition. By RICHARD LAKE, F.R.C.S., Consulting Surgeon, Royal Ear Hospital; and E. A. PETERS, M.D. Cantab., F.R.C.S., Surgeon, Royal Ear Hospital, and Surgeon, Nose, Throat and Ear Department, Bolingbroke Hospital. London: Baillière, Tindall and Cox. 1927. Pp. 310. 12*s.* 6*d.*

THE revision of this, the fifth, edition of Lake's Handbook of Diseases of the Ear, has been undertaken by his colleague, Dr. E. A. Peters. The book has gradually increased in size, but has not outgrown the dimensions of a convenient little manual for students and practitioners. The plan of the book has not been changed, and, except for a brief description of the anatomy and physiology of the cochlea and labyrinth, the additions deal mainly with the details of description and treatment necessary to keep the work up to date. The excellent colour plates showing pathological conditions of the membrane tympani remain a feature of the book, and their colouring and printing has been improved. Attention may be drawn to a few points which might be reconsidered when revision for a further edition is contemplated. The statement that "in all cases of non-suppurative middle-ear disease all errors of structures in the nose should be corrected and any tonsillar tissue removed" is too sweeping, and does not take into account the harm done to the reputation of the specialty by useless operations on the nose and throat in incurable cases of deafness. In the description of paracentesis of the drum no recommendation of general, or indeed of local, anæsthesia is given, and no mention is made of the extreme, though transitory, pain of this operation. On the subject of mastoid operations, it is stated that "Schwartze's operation should be reserved for children," and is apparently not advised for acute suppuration in adults. There is a misprint on p. 184, where ℥ii is written for ℥ii. The book may be cordially recommended as an excellent handbook of otology of a size suitable for general practitioners and students.

APPENDICITIS.

By HUBERT A. ROYSTER, A.B., M.D., Surgeon to Red Hospital; Surgeon-in-Chief, St. Agnes Hospital, Raleigh, N.C. London and New York: D. Appleton and Co. 1927. Pp. 370. 21*s.*

THIS monograph is an attempt to present to the reader an account of present-day knowledge of a very common disease. An interesting historical sketch is followed by chapters upon anatomy and ætiology, after which come accounts of the pathology, symptoms, treatment, and prognosis, including a special section on the disease in children. The author does not seek to bring forward any one special view, though his own conclusions, the result of a large experience, are noteworthy, and make the book worth reading. He has not been so successful in dealing with other subjects. For example, his account of the technique of appendectomy under local anæsthesia on page 298 could not be followed by any surgeon without reference to other sources of information, and the directions are so scrappy as to make us doubt whether the author

has actually himself employed this method. The treatment of a residual abscess is a point upon which many a reader will desire information. It is dismissed on page 345 in a paragraph of six lines. We can find no description of the technique of opening a pelvic abscess by the rectum or vagina, nor any discussion of the relative merits of the approach by these routes as compared with that from above. The instructions for dealing with a subphrenic abscess on page 346 are very poor. As to chronic appendicitis the author quotes the views of many men, but finds himself unable, from published work or his own experience, to "lay out any detailed symptomatology—there is none." Yet he believes in the existence of a true primary chronic appendicitis; this is an unsatisfactory situation in which other surgeons find themselves, and one which renders the decision as to operative treatment extremely difficult. The section headed "When to Operate" contains the original recommendations of Ochsner and Murphy; the author's views on this subject appear to us sound. We do not approve his recommendation (p. 302) to use a long external rectus sheath incision for general abdominal exploration—it is too mutilating; but his method of enlarging the McBurney incision in case of need seems a good way out of an irksome situation.

JOURNALS.

GLASGOW MEDICAL JOURNAL CENTENARY NUMBER.[1]—Last week we alluded briefly to the appearance of the Centenary Number of our well-known contemporary, but more than a passing note of congratulation is due to an issue which reflects faithfully in its various chapters the progress of the medical profession alike in its scientific, literary, and material aspects.

The Centenary Number opens with a series of concise biographies of the editors of the *G.M.J.* throughout the centenary, the history of the journal which they conducted emerging in this way. The first editor was Dr. William Mackenzie, a well-known ophthalmologist and linguist, who early secured for his pages a group of distinguished contributors. He was shortly succeeded by Dr. William Weir, first surgeon and then physician to the Royal Infirmary and for a time lecturer in phrenology in the Andersonian Institution. With Dr. Weir, in each case apparently only for a short period of time, there was associated Dr. James Lawrie, later Regius professor of surgery in the University and its first representative on the General Medical Council, and the exciting Dr. Andrew Buchanan, of whom the late Dr. Wallace Anderson wrote: "He wanted the tact, the discretion, the worldly wisdom of the successful editor"; but he evidently laid about him right and left, and in October, 1833, the journal came to an untimely but temporary end, not to appear again until 1851. On the re-issue Dr. William Weir returned as editor, a publisher-proprietor was found, and continuity for the rest of the period was maintained. Of the editors who followed many were, or became, distinguished figures in their profession, such as Dr. John Black Cowan, Dr. George Buchanan ("Wee Geordie"), Dr. William Leishman, the professor of obstetrics and father of the late Sir William Leishman, Dr. P. A. Simpson, and Dr. J. B. Russell. The appointment of the latter editor synchronised with the acquisition of the journal by the Glasgow and West of Scotland Medical Association, and Russell himself is famous for having built up the public health administration of the city. Russell was succeeded by Dr. Joseph Coats, Dr. Alexander Napier, and, among others, Dr. John Lindsay Steven, Dr. T. K. Monro, Dr. G. H. Edington, Dr. W. R. Jack, and the present editors, Dr. John Patrick and Dr. G. A. Allan. The biographies are adorned with portraits of many of their subjects, to some of whom a wealth of beard and whisker must have given an awe-inspiring appearance—we cannot imagine opposition to Dr. Andrew Buchanan being undertaken lightly.

[1] Glasgow: Alexander McDougall; London: H. K. Lewis and Co., Ltd. 5*s*. to non-subscribers.

A note from Sir Donald MacAlister on the medical school of the University from 1828 to the present day precedes fittingly a summary by Dr. Alexander Napier of the progress of therapeutics throughout the period; in this, while showing that the medical profession is to-day better equipped with weapons of precision for the acquisition of accurate knowledge, he lays stress upon the vista opened up to therapeutics by the discovery of the functions of the ductless glands and of the physiological action of certain of their extracts. Dr. G. H. Edington then exhibits the progress of surgery during the century by analysing the surgical contents of the first four quarterly numbers of the *G.M.J.* appearing in February, May, August, and November, 1828. The excerpts from these volumes give us a bird's-eye view of the state of surgical practice 100 years ago:—"disheartening for all concerned," he says, "were the conditions under which our predecessors worked—cramped as they were by the haunting spectre of sepsis and by the absence of skilled nursing." But the perseverance of these surgeons of old was such that, when light came with Lister, well-instructed and enthusiastic men were able to reap from the start much of the new advantages. Dr. R. M. Buchanan follows with a chapter on the evolution of bacteriology in relation to medical and surgical practice and preventive medicine, and here we find a résumé of the practical applications of bacteriology to the arrest of disease, to the development of sanitation, and to the rapidity and accuracy of diagnosis. Dr. A. K. Chalmers writes on the problems of medical administration in the early nineteenth century and later, and shows that Glasgow was among the first of the communities which helped to spread a knowledge of the protection against small-pox which vaccination afforded. The Faculty of Physicians and Surgeons of Glasgow in 1801 had instituted a vaccination station whereby an old obligation of the Faculty to visit the poor gratis, which had fallen into disuse owing to industrial conditions, was in a measure revived. This obligation played a part in the securing of the Charter of the Royal Infirmary, it being recognised that the physicians and surgeons had given gratuitous advice, assistance and medicines to the poor of the city until a regular and daily inspection became needed, the population having outgrown the range of a monthly medical service. The summary of the incidence of the zymotic diseases and of the part which preventive measures have played in controlling them in the city of Glasgow makes further interesting reading.

More topical are a series of chapters by Dr. John Henderson describing the position of extramural teaching in Glasgow in 1828 and its progress during the century; by Dr. John F. Fergus on the Glasgow hospitals of a century ago; by Dr. E. H. L. Oliphant on the Royal Faculty of Physicians and Surgeons of Glasgow, in which full acknowledgment is paid to the history of the Faculty published in 1896 by Dr. Alexander Duncan, and bringing the record down to the middle of the last century. Dr. David Rorie, co-editor of the *Caledonian Medical Journal*, congratulates his Glasgow colleagues on the part played by them in a story of progress; he sends an amusing contribution on the hardships of the old Scottish general practitioner.

Articles on medical journalism are written by Dr. T. K. Monro, formerly joint editor of the *G.M.J.* by the late Sir Dawson Williams, until a month ago the editor of the *British Medical Journal*, and by the Editor of THE LANCET. The first and last writers go over similar historical ground, while Sir Dawson Williams introduces to readers a medical journal, *Medicina Curiosa*, published in England, which has escaped previous attention. Book-hunters will be encouraged to look for this publication among bound volumes of miscellaneous pamphlets, for there were only two issues—namely, in June and October, 1684—and only three copies appear to be extant, both issues being in the library of the British Museum, but only the first one in the library of the Royal College of Surgeons of England.

THE LANCET.

LONDON: SATURDAY, MARCH 3, 1928.

APPENDICITIS IN CHILDHOOD.

ELSEWHERE in this issue we publish a report of a meeting of the Royal Society of Medicine at which the Sections of Disease in Children and of Surgery discussed chronic appendicitis in children. Though it is doubtful, strictly speaking, whether such a condition exists apart from comparatively rare cases in which the appendix is attacked by tubercle or actinomycosis, or occupied by threadworms, the clinician is probably justified in using the term to include a group of cases with characteristic symptoms, regardless of whether he can elicit a history of a previous acute attack. This may have caused so little constitutional disturbance as to have passed unnoticed, or its significance may have been missed, and in practice it matters little what the process is called provided that the appendix is justly blamed for the symptoms. At any rate in childhood, the acute condition is more common than the chronic, and its incidence is said to be increasing. The same is apparently true of appendicitis among the population at large, and it is disquieting to note that the death-rate attributed to this disease has also been rising considerably during the last two decades. The increase in mortality is said to be even greater in America than in this country; thus Dr. J. O. BOWER [1] compares an increment of 7·3 per cent. in England and Wales between 1913 and 1923 with one of 22·3 per cent. in the United States in the same decennium. Whilst too much may easily be made of such figures, which can be explained in various ways, most observers who have studied them return with increased vigour to the familiar call for earlier diagnosis. There is evidently something wrong with our methods or with their application, and the discussion last Friday, though directed entirely to chronic appendicitis, may well lead to a general consideration of the disease in the group where its mortality is admittedly highest.

Children offer certain difficulties both in the diagnosis and treatment of abdominal disease, and though they are almost immune from gastric and duodenal ulcer, from gall-stones and visceroptosis, they none the less have their share of abdominal misfortunes and a good deal more than their share of deaths from acute appendicitis. In the adult, this condition has come to be regarded as an incident and such anxiety as still remains is as often financial as personal; in a young child, however, it is always a calamity and only too often ends in catastrophe. Seeing that in the so-called chronic appendicitis there is little need for anxiety, it may well be asked whether we cannot convert an acute case into a chronic. Such a change is undoubtedly desirable, and it seems logical to aim at what Nature often seems to accomplish unaided. But, unfortunately, the attempt can very rarely be made with safety. It is the common experience of surgeons that children bear abdominal infections badly and that an inflamed appendix in a child is often two days in advance of what the operator expects to find; localisation of the infection is less complete than in the adult and general peritonitis more common. It is not too much to say, therefore, that any delay is unjustifiable after diagnosing appendicitis in a child, and such delay becomes more dangerous the younger the patient and the more acute the condition. In practice the difficulty lies in making the diagnosis, and postponement of operation is only justified so long as this is in doubt. Pneumonia, pleurisy, pyelitis, acetonæmia and (perhaps most puzzling of all) the enteritis or colitis of "influenzal" outbreaks, will sometimes baffle the most experienced clinician for a time. It is at this period of heavy responsibility that the Murphy teaching holds out a friendly hand; rest in the Fowler position, no morphia, nothing by the mouth, and the free administration of glucose solution by the rectum will do everything possible to limit the spread of infection while the diagnosis is in doubt. Close watch must be kept on the local physical signs, the pulse-frequency and the appearance of the child, for any of these may vary from hour to hour and will sometimes point clearly to the diagnosis. More often than a leucocyte count a second rectal examination has given the information on which operation could be undertaken. The nature of this operation, when decided upon, is naturally a matter for the individual surgeon, and though removal of the appendix is the proper treatment, all rules are made to be broken, and there are times when even the most enthusiastic subscriber to the truth will content himself with drainage and leave the appendix to a later occasion. This two-stage operation is sometimes necessary in very young children and those in whom the appendix is deeply buried in the thick wall of an abscess, but the risks involved in prolonging the first operation in order to remove the appendix are often justified by the jeopardy in which the patient is placed if suppuration extends into or around the liver and a spreading peritonitis supervenes. Each of these methods—postponement and immediate removal—has its advocates, and deaths seem sometimes to be due to following the one plan and sometimes to following the other. After-treatment offers further questions for discussion, but there are few anxieties for those who follow MURPHY, provided they remember that morphia and mouth-feeding are incompatible, and that he who withholds fluids by the mouth shoulders the responsibility for giving an adequate, measured quantity by some other means.

If it is necessary to broadcast statements about the gravity of acute appendicitis in childhood, they should be accompanied by a declaration that castor oil is much more dangerous than constipation. "Bilious attacks," particularly when abdominal pain is followed by vomiting, are often signs of appendicitis, and with such symptoms castor oil does everything which we most wish to avoid. The nursery medicine cupboard is no place for such a dangerous drug. Where the practitioner is in doubt of the diagnosis he will be wise to order the Fowler position and Murphy treatment while he is making up his mind; and it is always preferable to get surgical advice too soon rather than too late. Such is the preventive surgery of appendicitis.

THE EDINBURGH BILL.

WHICHEVER way it may be determined by Parliament, the controversy over the Edinburgh Corporation Bill will have a wholesome educative effect. As our readers are aware, the Bill is aimed at the person who defaults from his treatment for venereal disease before he is fully cured and while he is still liable to infect others. The medical officer of health is to be authorised to serve defaulters with a notice requiring them to consult a medical practitioner or attend treatment, and (unless they produce a certificate from the medical practitioner declaring them free from venereal disease) to undergo treatment until certified cured or unlikely to cause infection. This is not the whole of the Bill. If it is reasonable to require defaulters to complete their treatment, it is equally reasonable to require that persons who have not even begun treatment shall submit themselves thereto.

The Edinburgh Bill therefore provides that the medical officer of health may serve a similar notice upon any person whom he has reason to believe to be suffering from venereal disease and liable to infect others, if such person neglects or refuses to undergo treatment by a medical practitioner or at a treatment centre. Where the patients are under 16, these notices may be served upon their parents or guardians who are to be responsible for carrying out what the notice requires. So far, it will be seen, there is no conspicuous breach of the rule of professional secrecy; the matter is in the hands of the medical officer of health. It is on the next step in the Bill that the issue of secrecy is mainly raised, though the step is one not likely to be taken until after exhausting every effort to apply pressure on the patient to undergo treatment voluntarily. This step is the provision of machinery for securing the removal of a patient to hospital and his detention there if the medical officer of health certifies that he is suffering from venereal disease and is liable to infect others and that his removal and detention is expedient in order to prevent the spread of infection. The order for removal and detention may be made by a police-court either upon production of the certificate or upon adequate medical evidence of the necessity and desirability of making such an order in the public interest. The application for an order and the giving of medical evidence in the police-court are incidents which potentially jeopardise the principle of absolute professional secrecy. But there is to be no public disclosure; the Bill insists that all applications shall be heard in camera; it excludes from the court all persons except the patient, the medical witnesses, and the legal representatives. Those who cherish unqualified views of the inviolable liberty of the subject will no doubt dislike the element of compulsion in the Bill; they will also attack the further clause which would allow the medical officer of health to require parents to be medically examined and to undergo treatment if necessary where a child under 16 is found to be suffering from certain specified diseases of syphilitic or gonorrhœal origin. Defence of the liberty of the subject and defence of medical secrecy are two different matters. The medical profession is not so intimately interested in the former as in the latter. Liberty to spread a dangerous infection makes no strong appeal. If it were not for the question of secrecy, doctors would, we believe, have little hesitation in supporting the Bill. The Trevethin Committee (on which medical interests were well represented) recommended that the experiment of special measures for dealing with defaulters should be allowed for a limited time in a particular area where a case for such measures had been made out. Undeniably the City of Edinburgh has a strong case. It has in operation an admirably equipped scheme; it has been more successful in dealing with defaulters than any other part of the country. If it finds that nevertheless its defaulters average 1000 cases a year, it is justified in making some further attempt to reduce their numbers, to remove a public danger, and to avoid a disheartening waste of medical effort and public money.

Extreme insistence upon the merits of medical secrecy is, in our opinion, appropriate in protesting against the obligation to disclose a patient's confidences in open court—for example, in the course of divorce proceedings. We see no reason why the doctor should not be allowed to claim the same privilege in the witness-box as barristers and solicitors enjoy. But the supporters of the Edinburgh Bill are entitled to point out that the consequences of disclosure are vastly different when the proceedings take place behind closed doors and are unreported. The duty of secrecy may have to be weighed against other and possibly conflicting duties. Moral or legal, the duty to refrain from exposing others to infection is not merely a matter of venereal disease. If a medical practitioner would take strong action to prevent a thoughtless parent from sending to a public school a boy suffering from mumps or measles, is not equally strong action justified to prevent a venereal disease defaulter from spreading infection? The developments of recent decades have not been without their influence upon professional traditions. A system of State health insurance has introduced a third-party element into the old relationship of doctor and patient. The compulsory notification of infectious disease has meant another modification of ideas. Parliament has even (in the Bradford Corporation Act of 1925) made the experiment of applying notification to venereal disease in the case of grown-up persons who refuse or default from treatment and in the case of infant children. Do practitioners in Bradford find the existence of this statutory provision incompatible with their professional conscience? The Edinburgh proposals differ in character from the Bradford precedent, but the Edinburgh and Bradford provisions are alike in possessing a certain latent value, even if left inoperative. Medical officers of health will welcome the right to exercise such powers even though no medical practitioner is ever called into the witness-box. Critics may insist that, in the battle against venereal disease, no sharper weapon is to be used against the defaulter for fear of infringing the abstract principle of professional confidence. But they are incurring a grave responsibility towards posterity.

THE PHYSIOLOGICAL SOCIETY.

ON March 20th, 1926, the Physiological Society completed the first 50 years of its existence, though the jubilee celebration was not held till the following year, and to mark this memorable occasion Sir EDWARD SHARPEY-SCHAFER was requested to compile a history of the Society. This task he has now completed, and the history is published as a supplement to the *Journal of Physiology* for December, 1927. It is a volume of extraordinary interest. Glancing through its pages one might almost imagine it to be a "Who's Who" of modern British medicine instead of the domestic history of a single branch of medical science. Great names in medicine, surgery, pathology,

cteriology, and biochemistry appear on every page, d it is abundantly clear what an important part e Society has played, and what a powerful influence has exercised in the development of medical science. ne British School of Physiology is so famous that it difficult to realise that it is of comparatively recent owth. In the middle of the nineteenth century the untry which had produced WILLIAM HUNTER emed to be no longer interested in the exact study of e functions of the human body. While BERNARD, AJENDIE, MÜLLER, HELMHOLTZ, and LUDWIG were rsuing their brilliant investigations in France and rmany, in this country the teaching of physiology is carried out by surgeons and physicians, busy with eir private and hospital practice, and the science experimental physiology did not exist. But in iversity College, London, WILLIAM SHARPEY, who s professor of general anatomy and physiology, alised the importance of the study of function. He nself was not an experimentalist, but he had the ion to appreciate the fundamental importance of e experimental method, and he induced MICHAEL STER, a former student of University College and spital, to give up practice and to return to the llege as professor of practical physiology. The ching of physiology at University College, mentary though it was in its early days, soon began exercise a profound influence in the other London ools. Not only was the teaching improved, but lependent workers were encouraged to carry out estigations for themselves. Most of them, like VY, were engaged in active clinical practice, but ers, under SHARPEY'S influence, forsook clinical rk and devoted themselves wholeheartedly to the oratory. BURDON SANDERSON was one of these, d when in 1870 FOSTER was appointed on the gestion of HUXLEY to the newly instituted Prælec- ship of Physiology in Trinity College, Cambridge, NDERSON succeeded him in the chair of practical ysiology at University College. The foundations of tish physiology had been well and truly laid by ARPEY, and MICHAEL FOSTER at Cambridge and RDON SANDERSON at University College proceeded develop the two great schools of physiology which st in undiminished vigour to this day.

n all branches of human activity the need is felt, ner or later, of some organisation by means of ich workers in similar fields may be brought ether to their common advantage, and there is no ubt that the Physiological Society would eventually e been formed. But it is interesting to note that ysiologists were actually driven to form an associa- n to protect themselves and, what was more import- , the science to which they were devoted. The growth xperimental physiology and pathology necessitated eriments on living animals. Before long a wide- ead agitation against vivisection sprang up, and oyal Commission was appointed to investigate the ject. This was obviously only the preliminary to liamentary action, and it became essential that se interested in experimental biology should place mselves in a position to guard the interests of ntific medicine. BURDON SANDERSON invited the st prominent physiologists of the day to meet at house to discuss the matter, and suggested in his er of invitation the formation of the Society: will probably also be proposed at the meeting to n an association of physiologists for mutual efit and protection." This suggestion was acted n, and from this meeting of 19 men has grown the iety which now has a membership of upwards of . Sir EDWARD SHARPEY-SCHAFER was one of the inal founders, and we can well understand that the compilation of this history has been to him, as he says, a real labour of love. The extracts from the minute books are full of interest and have a personal touch which is, indeed, characteristic of the Society. Particularly happy are the numerous biographical notes. SIMS REEVES attended one of the meetings, but "it is not recorded whether he obliged the Company with a song." During the same year it was resolved that the number of ordinary members should be increased from 40 to 50. The number is now unlimited, and the original rule that every member should be a working physiologist has been abandoned, though it is noted in 1925 that some of the meetings were so largely attended that members had difficulty in seeing the demonstrations. Women were admitted to the Society in 1915 by a fairly substantial majority on a post-card poll, though it is curious to note that their presence was more welcome in the austere atmosphere of the laboratory than in the more social surroundings of the refectory. In 1916 the Society decided to publish *Physiological Abstracts*, and in 1926 it assumed control of the *Journal of Physiology*.

Enough has been said to indicate the profound interest of Sir EDWARD SHARPEY-SCHAFER'S compilation, and not only the Society, but the whole of the physiological world must congratulate him on an achievement which could not have been carried out by anyone else, and which called urgently for performance.

Annotations.

"Ne quid nimis."

MUTABILITY OF PNEUMOCOCCAL TYPES.

IT has long been known that certain species of bacteria, such as the meningococci and pneumococci, can be subdivided into serological types, and it has also been recognised that these types are more or less specific serologically, and from a therapeutic point of view necessitate the use of monovalent sera if the best results are to be obtained. What these differences mean and what the relation of one type to another may be is far less clear, but recent investigations of the serological types of pneumococcus, by Dr. F. Griffiths,[1] have thrown a certain amount of light on this obscure question and given results of considerable significance in other directions. Some time ago Griffiths found that the effect of growing pneumococci in immune serum was to produce so-called "rough" strains, which are avirulent and have lost their serological identity. He now finds that it is sometimes possible to restore these properties to the organisms by passing them through the animal body. This is a result by no means easy of achievement, since these attenuated types have little ability to establish themselves in the living animal; but it was discovered that the reversion to virulent type took place much more readily if a considerable mass of dead culture of pneumococcus was inoculated along with the living organisms. This suggests that there are certain constituents of the dead cocci which the living ones are able to metabolise and which are essential for their virulence, and pursuing this line of investigation in greater detail Griffiths found that pneumococci whose virulence was restored by this manœuvre assumed the type of the dead organism, instead of reverting to their own original type. Thus a rough form of Type I. inoculated with a dead culture of Type II. became transformed into the ordinary Type II. These phenomena seem to show that in the attenuated "rough" state the organisms are unspecialised and are capable of developing into any of the virulent fixed types according to what environmental conditions or pabulum

[1] The Significance of Pneumococcal Types. By Fred. Griffiths, M.B., Journal of Hygiene, 1928, xxvii., 113.

may dictate. The possible importance of these findings is more than academic, for it suggests not only a mechanism by which the virulent types may spring into existence from more lowly vegetative forms, but also a way in which the virulent organisms may disappear in the course of recovery and convalescence. It has commonly been assumed that in the latter condition the organisms died out, but there are difficulties in the way of universal acceptance of this view, and Griffiths's demonstration that in the presence of immune bodies organisms may mutate into an undistinguished form, suggests that an old and rather despised view, that they may lose virulence instead of dying out, may after all be correct.

THE WAR ON RATS.

Is a world war against rats worth while? The Danes and the other Scandinavian countries evidently think so, judging from a recent communication to the French Academy of Medicine by Dr. Gabriel Petit, in which he describes the dogged and successful fight put up by Denmark, and announces an international conference to be held this summer in France. The Danish effort began in 1898 with the formation of a national society and a demonstration of rat destruction in Copenhagen and Frederiksberg (virtually one town) on the premium system. This was imitated in 1900 by the Japanese, as the result of an outbreak of plague, and by other countries. France made a law in 1903, which was, however, limited to shipping. In 1907 the first Danish rat law imposed on district councils the liability of paying from ½*d.* to 1*d.* for each dead rat, and in three years nearly four million rats were killed at a cost of half a million shillings. As Dr. Petit points out, this was a profitable transaction, seeing that it does not take a rat long to eat and waste a shillingsworth of grain. As the rats grew scarce the small premium became less attractive and attention was turned to other methods of destruction. The second law (1910) left the choice of the method of destruction to the 1200 parishes, and during its five years' operation about 1½ millions of rats were destroyed at a price of 200,000 shillings. This rate of destruction was perhaps only sufficient to counterbalance the natural increase of the rat population. The world war caused a lull, but outbreaks of plague in Stockholm in 1919, and in Paris and Marseilles in 1920, revived interest in the matter among the Scandinavians. A third Danish law in 1921 put obligations on seaports to take energetic measures, and also established a general crusade. Every owner of property became liable to a penalty for failure to conform. The cost of the scheme fell on the district councils, and a Government subvention of 40,000 crowns was paid, partly as an encouragement, partly for dealing with public property. "Ratin," a bacterial poison of the paratyphoid group, and "ratinin," a preparation of *Scilla maritima* (*rubra*) became the accredited poisons. This time remarkable success crowned the enterprise, and when the third law came up for renewal in 1924 it was replaced by a permanent law, applying not only to ports, but to all towns and commercial establishments in Denmark, and the Government subvention was increased to 60,000 crowns. The Royal School of Veterinary Science and Agriculture was put in control of the methods of destruction. Dr. Louis Bahr, of Copenhagen, formerly assistant to Prof. C. O. Jensen, Director of the State Veterinary Service of the Serumtherapy Institute of the Royal School of Agriculture and Veterinary Science from 1906 onwards, has been responsible for the production of "ratin" and for seeing that its virulence is kept at a high pitch. As the result of the use of "ratin" it is estimated that at least 80 per cent. of the rats die within 8 to 15 days from enteritis or septicæmia and that, if destruction is not complete in three weeks, the standardised preparation of squill, which kills in 24 hours, will account for the remainder. It was in the year 1902, at a shipping congress in Copenhagen, that the International Society for the Destruction of Rats was formed, with Mr. Zuschlag, the enthusiast founder of the Danish Society, as first presider and Dr. Loir, one of the French delegates, as vic president. The outbreak of the world war prevent the proposed international congress in Copenhag in 1914, so that the French International Congress 1928, with sessions at Paris and Havre, may be regard as a resuscitation of international effort. The seapo of Havre, with Dr. Loir as the president of its Bure of Hygiene, has for many years been very active in t rat campaign.

In this country a useful booklet on the subje by Mr. A. Moore Hogarth has recently been issue it is called "Rats and How to Kill Them."[1] T same house published in 1924 a very complete a authoritative work on this question, entitled "Ra and How to Destroy Them," dedicated to Lo Aberconway and Sir James Crichton-Browne, two men who had specially drawn attention the rat menace. The author, the late Mr. Ma Hovell, F.R.C.S., showed the need for a mu more complete scheme in this country, unc scientific direction, and conducted by the larg local governing bodies. The book is a mine of inform tion. The author refers to the diseases other th plague which are spread by rats and to the enormo damage to our food-supply from their depredatio He shows that a pair of rats will eat or waste 5 lb. flour in a week, that a moderate estimate puts t rat population of the country at 40 millions, and th the damage done runs into millions and may be much as £1,000,000 a week. As a maritime count we should be specially interested in a world sche for rat extermination. In concluding his paper the French Academy, Dr. Petit quotes Prof. Calmet who, after praising the Danish effort and maki reference to the risk to health and the damage to wea from rats, said: "Such misdeeds clamour for reprisa We can no longer tolerate the ravages of rats. Again the serious and continuous menace from th activity, cunning, and fecundity we must pit o brains, our determination, and the scientific weapo we know how to forge for their destruction. L us unite internationally our forces and munitions war."

CHRONIC INFECTIONS OF THE SEMINAL TRACT.

Two papers were published at the close of last y which, under different titles, dealt primarily wi the treatment of chronic infections of the seminal tra The first of these was a paper by W. T. Belfield a H. C. Rolnick, in the December number of the *Jour of the American Medical Association*, entitled Obser tions on the Physiology of the Seminal Duct, and second one by Georges Luys, in the *Bulletin* of Société des Chirurgiens de Paris. In dealing with physiology of the seminal tract the American auth first discuss the function of the epididymis. Wy should the human spermatazoon, whose length s only 1/500th of an inch, be forced to traverse a tr of 20 feet—that is to say, of more than 100,000 tim its own length—before it reaches its destinatio The fact that in quadrupeds the seminal vesic if they exist, are solid glands that open direc into the urethra, suggests that the epididym which is always well developed in these anim acts as a reservoir for the storage of spermataz From this it is logical to deduce that it perfor the same function in man; this is certainly not only function. "During the mating season of snal birds, and mammals, the epididymis increases grea in bulk, its tiny cells become larger and more numero and the volume of these greater; with the pass of the mating season its bulk and secretion subsid the ante-nuptial dimensions." The provision o secretion is, therefore, an integral part of its funct The exact nature of this secretion is still unkno but the chemical analysis of the aspirated conte

[1] John Bale, Sons and Danielsson, Ltd. 6*d.*

spermatoceles suggests that it is the epididymis that is mainly responsible for the secretion of the proteins that are found in the semen. Belfield long ago called attention to the fact that the epididymis, like other secretory glands, is capable on occasions of acting also as an organ of excretion. This is proved by the fact that when dyes, such as methylene-blue, mercurochrome, and silver arsphenamin, are injected intravenously into dogs their colour appears in the body of the epididymis, leaving the head uncoloured. An obvious corollary to this is the possibility of influencing infections of the seminal tract by means of intravenous therapy. In the latter half of their paper Drs. Belfield and Rolnick describe cases of non-tuberculous seminal infection which yielded promptly to intravenous injections of neoarsphenamin or sulpharsphenamin. They therefore urge that cases of chronic prostato-vesiculitis, complicated by uncomplicated by arthritis or secondary iritis, should be treated by such means before resorting to surgical therapy.

Dr. Georges Luys, in his paper on catheterisation of the ejaculatory ducts, tabulates the indications for catheterisation under the following headings: stricture of the ejaculatory ducts; distension of the vesicles uninfluenced by prostatic massage; pain after ejaculation; hæmospermia; ejaculation without injection; congenital strictures: repeated attacks of epididymitis and azoöspermia due to obliteration of the ejaculatory ducts. He furnishes details of the technique of catheterisation with the posterior urethroscope that bears his name. Whilst admitting the difficulty of the operation and its impossibility in certain cases, he considers that the procedure may sometimes be feasible after careful treatment of the verumontanum by diathermy. The cauterisation of an œdematous and hypertrophied verumontanum will often render obvious ejaculatory ducts that were previously invisible. Whilst this method of treatment may be of great service, it must be carried out with restraint, as otherwise more harm than good may result.

THE OPIUM QUESTION IN PERSIA.

PERSIA is both a large producer and a large consumer of opium, and the problem which it presents in face of both The Hague and the Geneva Opium Conventions is a complicated one. Dr. A. R. Neligan deals with the subject [1] in the way that would be expected from one who has lived 20 years in that country, who was until recently physician to the British Legation at Teheran, and who has studied sympathetically and critically the medical and economic aspects of the use and abuse of opium among the Persians.

The cultivation of the poppy and the internal and external trade in opium are closely interwoven with the social and commercial life of the people of Persia, and a restrictive policy, applicable alike to production and consumption of the drug, is confronted by many difficulties. Some 600 tons of opium are produced annually in Persia and the money value thereof is about £2,000,000 a year, while the Government receives 9 per cent. of its revenue from opium. Half the total output is exported, mostly by way of the Persian Gulf, and largely to the Far East. Persian opium had at one time a high repute for pharmaceutical purposes, by reason of its rich morphia content, but it is maintained by the Government that Persia at the present time supplies less than 1 per cent. of the opium used for the preparation of morphia, heroin, and medicinal opium. Nevertheless there are some 3,000 acres under the poppy in Persia, some 300 tons of opium are consumed annually in the country, while 10 per cent. of the people are opium-smokers and one-fourth of the inhabitants of Ispahan are engaged, directly or indirectly, in this lucrative industry. If the figure postulated by the League of Nations as representing the medical or legitimate quantum of opium—12 lb. per annum per 10,000 of the population—be accepted, it appears that in Persia the consumption is at the rate of 459 lb. per annum per 10,000. If Persia, which signed, under reserves, both The Hague Opium Convention of 1912 and the Geneva Convention of 1925, but has ratified neither, is to be levelled up to the prescribed standard, it is obvious that there is much to be done.

The Commission which was recently sent by the League of Nations to investigate the special case of Persia reported on the financial aspects of the question and the possibility of substituting other crops for those of the poppy. The Persian Government has retorted that before doing so it must secure financial autonomy and control of customs tariffs, and urges that if it is to be rationed in regard to opium production the same restrictions must be applied to other producing countries as well as to those which cultivate the coca plant. The Government has, however, intimated a willingness, in due course, to reduce opium production by 10 per cent. annually for three years and then, in the light of the experience gained, to consider the effect such curtailment shall have had on the national budget, the trade balance, and the opium farmers respectively. Dr. Neligan, while fully recognising the magnitude and difficulty of the economic problems thus raised, is convinced of the physical and moral evils resulting from the non-medical use of opium. He thinks the abuse has increased greatly in recent years and is still increasing. He has observed the incompetence and slackness in men, women, and children from the abuse of the drug, and has witnessed the sapping of physique and moral in its addicts. He thinks that opium takes a tighter hold upon its victims than other narcotics, cocaine excepted, that moderation in its use is more difficult, and that, while it does not occasion the same organic lesions as alcoholism, its effects are definitely more weakening, especially on the moral side. In view of the exaggerated assertions of partisan writers it is well for serious students of the opium problem to read Dr. Neligan's able and reasoned statement.

CONGENITAL CATARACT.

ONE of the most unsatisfactory conditions that come to ophthalmic surgeons for treatment is the dense lenticular opacity sometimes present at birth. It is much more difficult to deal with than lamellar cataract, which is more common and seldom present at birth, being first found, as a rule, at a period of infancy when the child has had ample time to acquire the art of central fixation. True congenital cataract, when dense, makes central fixation impossible, and when, as is nearly always the case, it is bilateral, it gives rise to a permanent nystagmus, unless a successful operation or series of operations removes the obstacle to central fixation at an early age. The disadvantages of operation in very early infancy are obvious, and since congenital cataract is always a developmental defect and may be only one feature of a faulty growth—the eye may be micro-ophthalmic for instance—useful vision cannot be guaranteed even after apparently successful operative treatment. Cases first operated on at a later period are almost sure to be vitiated by nystagmus. A considerable proportion of the inmates of blind schools are children who have been operated on for congenital cataract, in some cases with apparent success, as far as the technique is concerned, but who display a decided nystagmus which reduces their vision, even with correcting lenses, to a point lower than that necessary for them to earn their living in ordinary ways. Further disadvantages of the accepted treatment of these cases have recently been pointed out by Dr. L. Webster Fox, of Philadelphia,[1] He suggests that there may be deleterious allergic reactions during the periods when the lens matter is being absorbed in the anterior chamber after each needling and he remarks on the danger of causing adhesions between the vitreous and the cornea (a

[1] Jour. Amer. Med. Assoc., Dec. 31st, 1927.

danger which could be avoided by entering the needle through the limbus). There is the further inconvenience, which in infancy may be prohibitive, of wearing spectacles with heavy lenses. As an alternative to needling he strongly advocates an optical iridectomy, in a single operation on each eye, which is comparatively easy to perform. This is frequently done in this country, both in cases of true congenital and of lamellar cataract, but it is only applicable when, with a dilated pupil, there is sufficient clear lens matter to form a fairly good peripheral pupil. The most important thing, from the point of view of the family doctor, is to decide at what period of infancy an operation should be undertaken. On this subject there appears to be some lack of agreement among authorities. Most would say as early as possible, and Fuchs says during the first few weeks of life.[2] Turok and Grout, in their text-book, say as early as the fifth month,[3] but Mr. Treacher Collins advises not earlier than the tenth month. "At an earlier age," he says, "the cornea is so small and the anterior chamber so shallow that the necessary instrumentation cannot be so satisfactorily carried out as in a more fully developed eye. Moreover, the amount of aqueous humour is so small that it does not suffice for solution of the liberated lens substance." For the pathology and treatment of the different varieties of this condition we can think of no guide so good as the article from which the above extract is taken.[4]

THE SO-CALLED PEMPHIGUS OF THE NEW-BORN.

THE Central Midwives Board, after an experience of nearly a quarter of a century, has come to the conclusion that the verbal description of pemphigus supplied to midwives fails to carry an accurate picture of the disease to those who read it. The Board is therefore circulating to all midwives a pamphlet with the best coloured drawing that could be obtained. The plate is taken from the fourth edition of the "Atlas of Dermochromes."[5] The little booklet accompanying the plate points out the importance of strict surgical cleanliness and draws the midwife's attention to the rule compelling her to send for medical aid at once, as well as to notify infection to the local supervising authority, and to disinfect herself. Pemphigus of infants is quite unrelated to pemphigus of adults and is a grave coccal infection of the skin which frequently ends in death from septicæmia. It has, however, some obvious relation with the impetigo contagiosa and septic sores of various kinds from which the nurse, midwife, or other member of the family may be suffering. In a recent paper[6] Dr. H. W. Barber points out that the characteristic lesion of impetigo is a blister varying in size from a pin's head to a hen's egg. It is formed just beneath the horny layer of the skin and is due to the outpouring of serum from the superficial vessels. The blister becomes secondarily invaded with staphylococci, and soon become turbid. There is, however, some evidence that the eruption may sometimes be due to *Staphylococcus aureus* in the first place, and it is possible that a virulent coccus might, in the virgin soil of a new-born baby's skin, cause lesions of a different type from those seen in older children. The size of the blister depends on the situation in which it arises. Where the horny layer is thin, as on the face, it is soon ruptured; where it is thick, as on the palms and soles, the blister may reach an enormous size. The *pyogenes longus* type of streptococcus is usually benign, but in new-born babies is very serious, probably because the infant has no acquired immunity. The point to remember, says Dr. Barber, "is that pemphigus neonatorum has nothing to do with true pemphigus or with syphilis; it is contagious impetigo of the large blister or bullous type occurring in ea infancy." When these facts are taken into conside tion it is obvious that no person with active pyoge infection of the skin should ever handle an infa Dr. Barber relates a story of a medical man wi chronic impetigo who had consulted him, and w told him that three babies in his practice had recen developed pemphigus.

Modern evidence is, in fact, entirely in favo of identifying this disease with impetigo contagio As long ago as 1909 F. Foerster, after giving numero instances of its infectivity, has stated categorical "there now appears to be sufficient evidence at ha to warrant insistence on the proper recognition pemphigus neonatorum as simply a bullous infant variant of impetigo contagiosa and elimination of t confusing term *pemphigus* when this affection under discussion." Yet the term pemphigus l remained in use up to the present day. It is true th syphilis sometimes, though rarely, produces blebs the new-born, but so does the acarus of scabies, a if an ætiological foundation is to be the ultimate a of nosology, it seems a mistake to continue to us name which, as all authorities are agreed, ignores t experimental and clinical evidence of years. T origin of the name appears to be lost in antiqui Dr. Edward Rigby, in the *Medical Gazette* of 18 (p. 125), used the term "pemphigus infantilis," a in his text-book dated 1794 F. B. Osiander speaks "pemphigus neonatorum s. connatus." Foers states that the disease was first described by J. Oehme in 1773.

HYPOGLYCÆMIA IN SCLERODERMA.

WITH the development of biochemistry and progress of knowledge in the obscure domain endocrinology there is a growing and healthy tende for a closer coöperation between the general physici the dermatologist, and the laboratory worker for purpose of attack on pathological problems. Am these, although fortunately it is a rare disease, th is none more striking than the complex of sympto termed scleroderma. The various types of locali and diffused varieties have at least one symptom common—the thickening and induration of skin—but many of them are associated with p dromal manifestations that remind one of Raynau disease, or with abnormalities of pigmentati sensory disturbances, and general asthenia wh may recall the later stages of Addison's disease. was presumably this latter syndrome which has to the belief, both in this country and on the contin that a disturbance of endocrine function was an æ logical factor in scleroderma. The theory seeme receive a certain measure of support from the sym matic improvement that follows the administrat of thyroid gland extract in some cases, and this of treatment is nearly always prescribed. It however, doubtful if thyroid can exercise a spe effect, for the failures are much more numerous t the cures. In his scholarly report from the med clinic of the Johns Hopkins University Dr. W. Longcope[1] has brought forward evidence wh tends to show that the endocrine disturbance is n probably a secondary than a primary phenome in the evolution of the disease. In one fatal cas acute scleroderma in a young man the auto revealed atrophy of one suprarenal gland and in stitial orchitis. The author's view is that the in stitial changes observed in the skin in every are by no means confined to that organ, but ca demonstrated in the connective tissue and bl vessels of the other organs. Such a process exten into a suprarenal or thyroid gland must affect t functions and accordingly lead to disorders of mentation, asthenia, alopecia, and low blood press such as are commonly associated with the dis under discussion, as they also are with Addis disease. This explanation readily accounts for uncertain action of thyroid gland administrat

l the author uses it ruthlessly to explain the poglycæmia he discovered in one of six cases scribed. He points out that the fasting blood-gar is also low in Addison's disease, as Porges first scribed, and that the other symptoms of that dition bear a close resemblance to those of sclero-ma. If nothing very positive has emerged from s report, it will at least create fresh interest, and d us to regard with scepticism the almost accepted ology of scleroderma on an endocrine basis.

TUBERCULOUS INFECTION IN INFANCY.

USEFUL information has been obtained from an estigation [1] entrusted to Miss M. A. Asserson by New York Tuberculosis and Health Association. e three-fold object was to ascertain the incidence uberculosis among groups of infants in a large city, determine the relation of exposure to infection, and discover what was the significance and course of ection in very early life. The procedure adopted luded a study of hospital and clinic records, ering a period of five years, of all infants who had n treated at two hospitals for various ailments and o had had routine tuberculin skin tests at the time their admission. Skin tests were also employed to ermine the incidence of infection among the general ant population, being carried out both at clinics l at health stations. It was found that in the spital group 8·2 per cent. of cases (excluding those h tuberculous disease) gave a positive result, ereas the percentage at the clinics was 4·5 and ong the healthy babies at the stations it was only . This shows that tuberculin statistics based upon spital experience alone should not be accepted as olicable to the general child population. The rate positive reactions was higher in Manhattan than in nx, which is in agreement with the conclusions of Framingham investigators that the incidence of erculous infection is highest in poor districts. The t step was to ascertain the after-history of 460 spital infants who had yielded positive tuberculin ts, and the cases were divided into the following ups :—

.—Infants suffering from advanced tuberculosis (pul-nary, miliary, or meningeal), 112 cases. Of these, 96 per t. died soon after admission to hospital.

I.—Infants suffering from tuberculosis of bones and ts or glands, 32 cases. Of these, 32 per cent. were found e dead, of whom just over half were stated to have died n tuberculosis.

II.—These had yielded positive skin tests but no clinical dence of disease, 316 cases. Skiagrams suggested enlarge-nt of tracheo-bronchial glands in 61 cases. Of these, per cent. had died of tuberculosis, 14·5 per cent. from er causes. Of the remainder (207), 39 per cent. had died death was attributed to tuberculosis in only 3·7 per cent.

The conclusion drawn from these figures is that istance to tuberculous infection in infants is higher n is generally supposed, a poor resistance to erculous disease being contrasted with a vigorous istance to infection. Histories of exposure to ection are, of course, often unreliable, and attention lrawn to an investigation made by the New York berculosis and Health Association in 1925, when it s found that the hospital records of 135 cases of erculous meningitis stated that there had been posure to infection in only 19 per cent. of the total. re careful inquiries proved that 56 per cent. of the ldren had been contacts of sufferers from tuber-osis, which indicates how misleading perfunctory estions may be. Miss Asserson rightly insists that posure to infection should mean contact with persons o are suffering from " open " tuberculosis, and that e type and length of such exposure should be noted. mparison of contact and non-contact cases proves t the mortality from tuberculosis is exceedingly h among infants exposed to family contact with e disease. Infants not so exposed, who receive ection in a more casual or incidental way from tside sources, develop a surprising degree of resistance. This contradicts the opinion of those who maintain that since infection is inevitable its source is a matter of small moment, and that the privilege of motherhood should not be denied to a woman because she suffers from active phthisis. In this connexion it may be noted that of 40 infants who remained in contact with phthisical mothers 65 per cent. died of tuberculosis, while of 37 infants " boarded out " only one died of the disease though all had been infected. The highest death-rates were recorded among those who had been exposed to infection at earliest ages. Miss Asserson concludes that " Such unnecessary waste of infant life, as is shown in the deaths of the 120 infants in this study who died of tuberculosis, the majority because they were continuously exposed to the disease, must make us pause to consider whether or not we are facing and assuming a responsibility which rests upon us to protect the most susceptible of human beings from this preventable disease." The question is equally pertinent on the two sides of the Atlantic.

FASTING BLOOD DONORS.

IT has long been recognised that the reactions which may occur after blood transfusions can be differentiated into those caused by the group peculiarities of incompatible bloods and those due to some other undetermined cause. The former are sometimes very serious, but fortunately rare ; the latter are relatively common in some operators' experience, but are hardly ever serious, even if distressing to the patients. Many different causes have been assigned for the lesser reactions—e.g., sodium citrate, cooling of the blood, use of rubber tubing, destruction of leucocytes—but none has seemed to be conclusive, and the hunt has continued. A new hare has lately been roused by Drs. Brem, Zeiler, and Hammack,[1] at Los Angeles, which may reward pursuit. These observers had occasion to administer nine transfusions over a period of six years to a patient who suffered from a bleeding duodenal ulcer. After some of the transfusions he had somewhat severe reactions, after others he had none. An attempt to discover the reason for the different results revealed the fact that a reaction appeared to follow the use of a recently fed donor, but that it was absent if he had fasted. The suggestion is therefore made that the reactions may be due to the toxic effect of products of digestion in the donors' blood, and that a donor should avoid all protein food for some hours before giving his blood for transfusion. The suggestion is obviously still in the realm of speculation, the number of observations so far made being very small.

NURSES IN MISFORTUNE.

TO make provision for old age, to prepare a few defences against misfortune—these are wise precautions for all who earn their living. Nowadays this is so generally recognised that many forms of employment carry an obligation to subscribe to pension and insurance funds, and a feeling has arisen in consequence that only the improvident can find themselves in destitution. But the solicitude of employers and facilities for self-protection have not always been what they are to-day, and in certain walks of life there are survivors from another epoch whose unhappy condition, made worse by the war, demands generous assistance. In considering the hard lot of the women to whom attention is directed by the Nurses' Fund for Nurses, it will be remembered that those who entered the nursing profession 30, 40, and 50 years ago were little encouraged by the hope of a comfortable life or adequate remuneration. Most of them must have begun their work from a desire for useful service, and some of those who have most conspicuously failed to help themselves have done so because their heart was in helping others. For this reason we have watched with sympathy the scheme of relief started by Miss S. Bulan and carried on under

difficulties during the past two years. The *Nursing Times*, of which she was until lately the editor, has recorded week by week an admirable attempt to find the most unfortunate members of the nursing profession and give them whatever help was possible. Though money is not always their only, or indeed their chief, need, this work has involved a good deal of expenditure, and since the fund established a home in Clapham where aged nurses may live without anxiety for the future, its financial responsibilities have been heavy. The original intention was to ask subscriptions only from members of the nursing profession, and the £3127 so far collected has largely come in small sums from that source. But there is so much more to do, and so real a need for money that the fund's promoters would be grateful for help from other quarters. Patients sometimes ask how they may express thanks for careful nursing, and this appeal suggests a way which may commend itself. Some of our readers, too, may themselves be under an obligation which they would like to recognise by contributing to the fund. Condescension, begging, over-organisation, and the other incidentals so often associated with giving money are none of them in question here; for it will be long before the community ceases to be in debt to the nurses—especially, perhaps, those of the last generation—and anyone who sends a subscription to the hon. secretary of the fund (c/o the *Nursing Times*, St. Martin's-street, London, W.C. 2) may rest assured that it will be used with understanding.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lt. E. C. W. Maxwell to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Capts. C. A. Slaughter (Prov.), H. A. Boyle, and T. E. B. Beatty (Prov.) to be Majs.

Temp. Capt. J. R. P. Allin relinquishes his commn., and is granted the rank of Maj.

Lt. A. E. Campbell to be Capt.

Temp. Lt. J. W. Kendall to be Lt. on prob., and relinquishes the Temp. rank of Lt.

Lt. (on prob.) J. H. Anderson, from the secd. list, is restd. to the estabt.

ARMY RESERVE OF OFFICERS.

R. W. Agnew to be Lt.

SUPPLEMENTARY RESERVE OF OFFICERS.

A. Roberts to be Lt.

TERRITORIAL ARMY.

Maj. C. Douglas, T.D., having attained the age-limit, is retd., and retains his rank with permission to wear the prescribed uniform.

Capt. D. C. Bowie, R.A.M.C., to be Divl. Adjt. 54th (E. Anglian) Div., vice Maj. E. Phillips.

ROYAL AIR FORCE.

Flight Lt. H. Penman is granted a permanent commn. in this rank.

INDIAN MEDICAL SERVICE.

Temp. Lt. Devendra Nath Chakravarti to be Temp. Capt.

Temp. Capt. C. L. D. Roberts, whose relinquishment of temp. commn. has been notified, is granted the rank of Capt.

Capts. Shridhar Atmaram Phatak and R. A. Warters to be Majs.

Col. R. W. Knox retires.

DEATHS IN THE SERVICES.

Sir ROBERT PORTER, K.C.B., C.M.G., Director of Medical Services of the Second Army in France, who was taken ill with a commencing attack of pneumonia while awaiting the arrival of the coffin of his old comrade Earl Haig, at Westminster Abbey, died at his residence in Beckenham on Feb. 26th in his seventy-first year.

Modern Technique in Treatmen

A Series of Special Articles, contributed by invitatio on the Treatment of Medical and Surgical Condition

CCLXV.

TREATMENT OF DISTURBANCES INCIDENTA TO EARLY MENSTRUAL LIFE.

IT is of considerable importance to a girl that h guardians and medical adviser should realise that t menstrual function, from its onset, should be fr from any disturbance of a pathological nature.

I will not refer to the physiological changes whi take place at puberty, except to those which a sometimes treated as though they were abnormalitie The pathological disturbances may be consider under the following headings: Primary Amenorrhœ Secondary Amenorrhœa, Dysmenorrhœa, Menc rhagia, Neurotic Disturbances.

Primary Amenorrhœa.

It is sometimes difficult to decide if a case is o of primary amenorrhœa or of delayed developmer If a girl has not begun to menstruate by her sixteen birthday it is usual for the mother to seek advic This delay in the onset need not in itself cause anxiet In my experience the age of onset has varied betwe 8 and 19 years, and in both extremes normal woma hood has supervened. In all cases, however late t development, some growth, both in height and weigh has occurred for at least a year after the first menstru period. This fact may be helpful in prognosis.

Before one is justified in reassuring the moth with regard to a girl over 16, in whom the mens have not appeared, the following particulars should ascertained: 1. That the health is good. 2. Th the secondary sexual characteristics have develope 3. That growth is continuing, and that there is sudden fall in the *rate* of growth, especially with rega to weight. 4. That there is no abnormality found medical examination. This should include inspecti of the hymen and a pelvic examination per rectu by which any gross abnormality of the genital orga may be excluded. It must be remembered that atres of any part of the genital canal may be the cause apparent amenorrhœa.

If all these conditions are satisfactory it important that both mother and daughter should ha their minds set at rest, and be told that no treatme is necessary. If, on the other hand, the girl is in go health, but growth appears to have stopped, or to definitely diminishing in rate, a more serious view mu be taken, and an attempt should be made to stimula development of the generative organs by endocri therapy. Treatment by small doses of thyro substance (with or without anterior pituitary) or multiglandular tablets, is sometimes followed short by further growth and the onset of the menses. B it seems impossible to know if, in these rare cas the course of nature has been affected by such ther peutic measures, especially as it is not so ve uncommon for growth to stop for a time and then recommence without any medical interference. cases where secondary sexual characteristics have n developed before growth has ceased I have seen sign of development of the sexual organs aft prolonged treatment.

Secondary Amenorrhœa.

In addition to the minor irregularities of periodici so common during early menstruation I have notic three types of secondary amenorrhœa in young gir

Type 1, in which amenorrhœa, lasting six mont or more, sets in after the first few periods. This of frequent occurrence in children who begin menstruate early—at the ages of 10, 11, or 12—a must be of developmental origin.

Type 2, in which amenorrhœa, lasting for three nine months, occurs in girls in whom regular menstru tion has been established for some years. Th

enomenon is common in those who have experienced me change in environment. The same thing may cur after a shock or an operation on any part of the dy, and is probably due to an upset of the endocrine lance due to emotional disturbances.

Neither of these two types of amenorrhœa is sociated with anæmia or ill-health. No treatment called for except to reassure a nervous patient.

Type 3.—The third type of amenorrhœa has a eater significance. It occurs too late to be of velopmental origin and is not associated with ange of environment. In young women of 17 or er in whom pregnancy, anæmia, tuberculosis, or her specific disease, both local and general, can be cluded, the onset of amenorrhœa, especially if it associated with insomnia or other symptoms of urosis, cannot but give cause for anxiety, since the ndition is not infrequently linked with a morbid ychology and may even be a forerunner of insanity. ese are cases in which glandular treatment may have definitely beneficial effect. The administration of yroid substance (a quarter or half a grain daily) d of small doses of multiglandular preparations has en followed by the recurrence of regular periods and increase in the general welfare of the patient. But apses may occur if the treatment is discontinued d administration of the remedies must go on for an definite period.

Dysmenorrhœa.

This term is here used to mean any suffering finitely associated with the menstrual period. eatment in the first place should be prophylactic d the measures I would advocate are: (1) That all ls be taught that menstruation is a natural function d should not involve any pain or disability, and that change need be made during the period in their dinary habits with regard to baths and exercise or ain-work. (2) That school authorities be urged to scind rules restricting the natural activities of ildren during menstruation, and that cycling, mnastics, and games, such as hockey be allowed.) That employers of young women engaged in dentary and standing occupations be urged to ovide opportunity for daily exercise, such as illing, the exercise to be continued throughout the riod. This has proved to be of mutual advantage employer and employed in factories.

When dysmenorrhœa has become established the eatment I adopt, after assuring the patient that her ffering is unnecessary, has a two-fold object:) To stimulate the circulation of the blood in order relieve the hyperæmic uterus. The quickest means doing this is a hot bath; the more lasting measure is gorous exercise. (*b*) To direct the patient's attention from herself by providing interesting occupation. ence games or active work are preferable to set ercises.

The most beneficial exercises are those involved in: cking up objects from the floor and placing them on shelf above the head; kneeling and swinging the nds round alternately as if polishing the floor; uatting on the floor and bending to and fro, as in wing; and standing and doing swinging movements, in driving a golf-ball. All these movements can be ecuted in a small bedroom and if they are practised r 10 to 15 minutes daily for a week before the onset, d continued throughout the period, the pains will t develop or will be so slight as to be negligible. In vere cases the exercises may have to be repeated ring the day. After three months they can nerally be relaxed with impunity. For nervous tients it is useful to prescribe a sedative, such as b. acetanilid co. (B.P.), to be taken thrice daily the day preceding and for the first two days of e period. In no case do I consider that the operaon of dilatation, with or without curetting, is stifiable treatment for dysmenorrhœa in a young rl whose generative organs are healthy.

Menorrhagia.

Uterine hæmorrhage, severe enough to be called enorrhagia, is rare in young girls. The flow is sometimes rather excessive for a few periods, and, until the normal loss is established, outdoor games and sports during the period must necessarily be restricted; but they should be replaced by exercises at home suited to the severity of the condition. The exercise in the kneeling position is useful for this. In cases of true menorrhagia, where the periods, previously normal, have become persistently prolonged and the flow excessive, the cause in young girls is generally a toxæmia. A septic focus should be looked for and can often be found in adenoids, tonsils, or teeth, or in a chronically infected appendix. Severe constipation may be the sole cause of the trouble even when regular evacuations are reported.

Neurotic Disturbances.

The occurrence of irritability, increased emotionalism, depression, and other symptoms of nervous instability during the menstrual period has, I think, been over-estimated. These symptoms are certainly rare among girls who are expected by their elders to remain well during the period, and are often only detected by those who expect to find them. It is found that teachers who have not been informed are not, except in rare instances, able to detect when their pupils are menstruating. Nevertheless this type of neurosis certainly exists, and the victims can generally be cured by what might be called "verbal treatment." I have usually found it successful, and there is no doubt that in many the nervous disturbance has in the first place been induced by suggestion. Who would not be depressed on being told, at the age of 13, that, in future, she would be an invalid for three days every month? Prevention is therefore in most cases dependent on a sensible upbringing. When there is pain or discomfort the presence of neurotic symptoms is not surprising and the treatment for both conditions is the same—namely, employment in some interesting active work or game. It is for the purpose of discouraging introspection, which leads to these neurotic states, that I advocate outdoor games or active work rather than set exercises as a cure for menstrual disorders.

ALICE E. SANDERSON CLOW, B.Sc., B.S., M.D. Lond.
Cheltenham.

DONATIONS AND BEQUESTS.—Among other bequests Mr. Francis Stanley Holland, of Hove, Sussex, and Eastcheap, London, left £1000 to the Royal Sussex County Hospital.—Mr. Walter Skaife, of Southend-on-Sea, who left £35,707, on his wife's death, after certain legacies, left the ultimate residue of his property equally between St. Bartholomew's Hospital, Dr. Barnardo's Homes, the London Hospital, and the Victoria Hospital, Southend-on-Sea.—The Liverpool University Students' "Panto Day," after the deduction of £400 for expenses, yielded £5000 for the city hospitals.—The late Mr. Edwin Pope, of Dorchester Brewery, has bequeathed £5000 to the Dorset County Hospital.—The late Mrs. Clarissa Ellen Slyman, of Thorncliffe, Urmston-lane, Stretford, Lancs, left among other bequests £1000 each to St. Mary's Hospital, Manchester, and St. Dunstan's Blinded Soldiers' and Sailors' Hostel; £350 each to the Royal Infirmary, Manchester, and Dr. Barnardo's Homes; and £250 to the Liverpool, the Devonshire Hospital, and Buxton Charity, Buxton.—Mrs. Mary Jane Bradley, of Lyndhurst, Huby, Weeton, Harewood, Yorks, left by her will £1000 to the Leeds General Infirmary in addition to bequests to other charities.—Mrs. Adelaide Florence Henderson, of Rosebank House, Wick, left £15,000 and her residence Rosebank and ground therewith to the Wick and Pulteney District Nursing Association, to establish, equip and partially endow a nursing home in Wick in memory of her sisters and herself, to be known as "The Henderson Memorial Nursing Home," the interest of £2000 towards the running expenses of the ambulance car she lately presented to the County Council, £500 each to the Nicholson-Mackenzie Hospital, Strathpeffer, and the Bignold Cottage Hospital, Wick, and part of the residue of the estate to the Sick Children's Hospital, Edinburgh.—Mr. Alfred Ernest Briggs, of Low Moor, Bradford, Yorks, left £500 to the Bradford Royal Infirmary and the ultimate residue of his estate in trust for the erection of almshouses for the poor of Low Moor.—Mrs. Laetitia Elizabeth Beeston, of Clevedale, Winchester, left £1000 to the Royal Hants County Hospital and £1000 in trust.

Special Articles.

A COMPARISON OF COMPULSORY SICKNESS ASSURANCE IN VARIOUS COUNTRIES.

THIS volume [1] is the outcome of the decision of the International Labour Conference in 1925 to collect and publish information on the progress and working of social insurance. It presents the results of a systematic examination, based on facts obtained from 24 countries, of the essential aspects of compulsory sickness insurance considered under the following headings: scope; benefits; financial resources and their management; institutions and supervisory authorities; disputes, judicial authorities, offences and penalties; the situation of foreign workers. The labour involved in the preparation of the book must have been enormous, for it has been necessary "to summarise 350 laws and regulations, 220 reports of various kinds (representing tens of thousands of pages of legal or technical works, and thousands of statistical tables) written in some 15 languages." The result is an octavo volume of nearly 800 pages presenting a systematic review, unique in its range and authority, of the present position of compulsory sickness insurance throughout the world. Though packed with facts and figures, the matter is so methodically and conveniently arranged that the inquirer can readily pick out any particular kind of information he may require. To those interested in the promotion of the public health it is an invaluable document.

Compulsory insurance against sickness is a comparatively recent addition to the measures taken by the modern State to promote the health of its members. It began in Germany in 1883, and was first applied only to certain industrial groups, to which large additions were made in 1885 and 1886. The example of Germany was followed by Austria in 1888 and Hungary in 1891, but it was not until the twentieth century that any considerable extension took place. Since the war progress has been rapid. The movement has spread beyond Europe; Japan adopted compulsory insurance in 1922 and Chili in 1924, and it is probable that other countries will follow in the next few years. As might be expected, there are wide variations in the insurance schemes in operation in the different countries in regard to the classes of persons insured, the methods of administration, and the character and extent of the benefits. For instance, the proportion of insured persons varies from 3 to 35 per cent. of the total population, and from 15 to 86 per cent. of the employed population. The scheme may apply only to workers in certain specified callings—e.g., to miners or seamen, or to those employed in undertakings of a certain size or exposed to exceptional risk of disablement. In some countries agricultural workers or domestic servants are excluded. There are similar variations in the methods of working the various schemes and in the benefits conferred by them.

Modern Tendencies of Sickness Insurance.

But when the schemes are considered as a whole certain broad lines of tendency emerge, and it is because of the material it offers for the examination of these tendencies that the present volume is chiefly of value to the student of social conditions. It would seem that compulsory sickness insurance once established tends generally to develop on certain lines. Occupations at first excluded from the scheme tend later to be included in it. In the last 15 years no less than ten countries have brought agricultural workers within the scope of compulsory insurance, and th exclusion of domestic servants and temporar workers has in most countries been removed. In shor compulsory sickness insurance tends to cover the who class of wage-earners, including non-manual worke of small means. On the other hand, voluntary insu ance shows no tendency to extend. Many compulsor schemes have a voluntary side, but with ra exceptions it has attracted very few entrants. Great Britain the number of voluntary contributo was insignificant before the Widows', Orphans,' ar Old-Age Contributory Pensions Act offered addition and substantial advantages to the insured populatio

It is, however, in the development of the benefi given by the various schemes that the most inte esting tendencies of modern sickness insurance emerg In determining the nature of the benefits two polici may be adopted. One is to grant the disabled insure person a benefit in cash, so that he may purchase wh he thinks he requires, within the limits of the su available. The other is for the insurance institutio to shoulder the responsibility of providing him wi what is essential to restore his power to suppo himself. In most countries both kinds of provision a made, but there is a strong tendency to develop th second policy and make benefits in kind mo important than benefits in cash. In the early da the chief object was to secure for the disabled work certain payments in place of the wages that sickne prevented him from earning. The insurance contrib tions were regarded as something in the nature savings deposited for the purpose of being drawn o on the arrival of a "rainy day." But this savin bank notion has developed into a much broad conception of insurance benefits and insuran purposes. Merely to provide the sick worker wi money to enable him to tide over a period of enforc incapacity is now generally regarded as an insuran function of minor importance. The modern aim is effect a complete and rapid restoration of worki capacity and to provide whatever may be reasonab necessary to attain this aim.

Medical Services.

From this point of view the provision of medical ca is obviously essential, and it is important that t doctor should be available at the earliest possib stage, when the prospect of care is most promisin There are very few schemes of sickness insurance th do not provide medical treatment, and in nearly countries it is available upon entry into insuran without a waiting period such as is required befo cash benefits can be paid. There are variations in t range and nature of the medical provision made, b the general practitioner is the foundation upon whi all the systems of medical services rest. He is ever where the first and most essential element. B specialist services are also widely provided. In so countries—e.g., Germany, Austria, Czecho-Slovak Hungary, and Poland—the insurance institutions a under obligation to provide specialist treatment, wh in most other countries such provision is option and the option has been widely exercised. Dent treatment forms part of the benefits given by most the insurance schemes, especially where the preventi value of dental services is most clearly appreciate Hospital treatment, including maintenance, thou usually an optional benefit, is very widely provide and the cost of removal is borne by the insuran funds and forms part of the benefit. Home nursing a form of special assistance provided in five countri

Family Provision.

Maternity benefit is an element of increasing impo ance in social insurance. In a few countries, as Great Britain, it takes the form of a cash payme only, but usually assistance in kind is also provide including the services of midwives, and, if necessar medical attendance together with any medici required. Admission to a maternity home may secured, and in many countries the insurance instit tions give to mothers who nurse their babies "nursing bonus"—i.e., a weekly allowance payab

[1] Compulsory Sickness Insurance. Comparative Analysis of National Laws and Statistics. International Labour Office Studies and Reports. Series M (Social Insurance), No. 6. Published in the United Kingdom for the International Labour Office (League of Nations) by P. S. King and Son. 1927. Pp. 794. 12s.

ually, for 12 weeks after the confinement. Maternity nefit is far from being restricted to insured women ; 14 countries it is given to the wives of insured men virtue of the husband's insurance, while in five untries the benefit is extended to other members the insured person's family—namely, daughters, nd-daughters, and sisters if they are dependent on e insured person and are members of his household. is extension is compulsory in Austria, Germany, and land, and optional in Czecho-Slovakia and umania.

The provision of maternity benefits for the wives d other dependent members of the insured person's usehold introduced into social insurance an element special significance. It gave expression to the nception that the real unit for insurance purposes not the individual worker, but the worker together th his family, and that no insurance system can be garded as complete that does not provide for the dical care of the insured person's dependents. is conception of the function of sickness insurance s made rapid headway since the war, and in most untries the provision of medical treatment for the pendents of the insured is either a compulsory or an tional benefit. Usually the dependents receive the ne range of medical services as the insured persons, t in certain countries such special forms of provision spa treatment or treatment and maintenance in valescent homes are reserved exclusively for the ured.

The social importance of this development is viously considerable and likely to have far-reaching ults. By making medical care freely available for children the influence of sickness insurance in the d of prevention has been greatly extended. The tor can be called in early, infection detected in an ly stage and brought under timely control, serious ease can be attacked in its beginnings when the spects of success are most promising, and skilled ice can at all times be secured during those critical ly years of life which have so important an uence on the health of the worker when he reaches period of productive activity. The preventive ect of family provision is fully realised by those ponsible for the administration of insurance emes on the continent, in which preventive work ds to take an increasingly important place. It is, fact, the latest and perhaps the most significant elopment of sickness insurance. In various ntries recent legislation has given the sickness ds wide powers to take preventive action, and many making extensive use of these powers. Health ruction is given by means of lectures, health ibitions, &c., and through the medium of the press the cinematograph ; antenatal consultations have n established, holiday camps for children organised, in various ways the funds participate in the fight inst tuberculosis and venereal disease and for the tection of child life.

The Organisation of Medical Services.

The book contains a chapter on the organisation of lical services which is of special interest to lical readers. In nearly all the countries in ch compulsory sickness insurance has been blished the institutions responsible for the ment of cash benefits are responsible also for the vision of medical services, although not infrequently duty is carried out not by the individual institus but by their federations. The most important ption is to be found in the British system, in which arrangements for medical treatment are made, by the approved societies, but by the insurance mittees. In Esthonia and Latvia the employers responsible for medical provision, while in Russia responsibility devolves upon the public health horities. On the continent the conditions under ch medical practitioners undertake service vary siderably, not only among the various countries, also within the same country, and there are lar variations in regard to the right of the insured on to choose his doctor. There appears to be a ving tendency for the insurance institutions to provide themselves with an elaborate medical equipment. The Berlin Federation of Sickness Funds has established 40 clinics, each being responsible for the treatment of the insured persons and their families living in a certain area. In Poland the sickness funds had by the end of 1924 no less than 312 clinics, 116 pharmacies, 55 hospitals, and 7 sanatoriums. Similar provision on an increasing scale is being made in Czecho-Slovakia. This subject might with advantage to the medical reader have been treated in fuller detail and with a critical discussion of the principles involved and the difficulties encountered, so that an unwary reader might not carry away an impression of a harmonious adjustment of varying interests which a closer acquaintance with local conditions might possibly modify.

It is impossible, however, to make even a cursory study of this book without being profoundly impressed by the magnitude of the social movement it describes. Compulsory sickness insurance has created a vast network of organisations endowed with wide powers and disposing of large funds. How to direct these immense new forces to the best advantage is one of the most important public health questions of the present day.

THE THIRD RACE BETTERMENT CONFERENCE.

FROM Jan. 2nd to 6th there took place at Battle Creek, Michigan, U.S.A., the Third Race Betterment Conference. The official purpose of these conferences is—

"to bring together a group of leading scientists, educators, and others for the purpose of discussing ways and means of applying science to human living in the same thoroughgoing way that it is now applied to industry—in the promotion of longer life, increased efficiency and well-being, and of race improvement."

As many as 60 addresses were delivered in the course of these four days by different speakers. The subject matter of the conference, as dealt with in these addresses, roughly falls into the following divisions: eugenics and heredity; public health, immigration, and longevity; nutrition; and a miscellaneous division comprising such heterogeneous topics as athletics for women, newer values in education, the therapeutic value of sunlight, the future of the Red Indians, the cultural value of advertisements, and the bearing of the conditioned reflex upon no less a subject than "moral hygiene." Only the salient points arising from these addresses can be dealt with here.

Eugenics and Heredity.

In the direction of "negative" or restrictive eugenics, an address was given by Dr. Paul Popenoe dealing with sterilisation in California. Up till January, 1927, 5000 sterilising operations have been performed in this State, 4000 of them in the State hospitals for the insane, and 1000 in the State home for the feeble-minded. There have been four deaths in the course of these operations—a man and a woman from ether anæsthetics, and two women from peritonitis. Apart from these official State-controlled operations, it is estimated that some 2000 women have been voluntarily sterilised in private practice. In Michigan, wherein there exist a minimum of 73,000 feeble-minded, sterilisation has been performed in 111 cases. Of this procedure, Dr. H. E. Randall said that no one expected, by it, completely to eliminate mental defect from the community since the condition was frequently "carried," in the genetic sense, by normal persons. Yet it was reasonable to hope that, by the process of sterilisation, the contamination of the general population with the taint of latent mental defect would, in course of time, be diminished. The reports upon patients operated on in Michigan do not bear out the contention that the measure promotes loose moral conduct and spreads venereal disease. Dr. Randall also says: "We have seen no improvement, as Steinach reports, in the direction of rejuvenating old men. Our own impression is that none have been made worse. All have recovered promptly and the operation has led to a cleaner moral life of the paroled."

Much evidence was advanced of the supposedly harmful influence on the national stock of differential fertility. Thus an investigation by Prof. Alsworth Ross revealed

"that the average number of children born into 100 dependent families of American stock was 2½ times the number born from 2200 families of the same stock who had a son, a daughter, a nephew or a niece in college." Prof. E. M. East also dwelt upon the dysgenic tendency of America's increase of population. He is of the opinion that this tendency can best be checked by "spreading a clearer genetic point of view among our physicians." Dr. E. J. Hickson, director of the Psychopathic Institute, Chicago, laid stress on the very close relation between the defective and criminal classes in his city, each of which classes amounts to some 2 per cent. of the population. But this 2 per cent. absorbs 35 per cent. of the gross taxes in addition to being a source of considerable anxiety to the remaining 98 per cent. Dr. Hickson's wide experience of this class of criminal defective has led him to advocate depriving it of political power by a system of proportional voting. In connexion with the relative influences of heredity and environment in the creation of criminal and defective types, there was some difference of view. Dr. Riddle, of the Carnegie Institute, advanced a plea for the foundation of another institute for the study of the influence exerted by environmental conditions upon hereditary characteristics. But Dr. Henry F. Vaughan, Commissioner of Health for Michigan, so doubted the value of improved "nurture" that he advocated sterilising burglars. He further urged that "those who show themselves, during school life, to be low-grade morons, should be desexed (i.e., presumably, sterilised) before the reproductive age."

Public Health, Immigration, Vital Statistics, and Longevity.

Dr. Alexis Carrel described his experiments on the immortality of tissues and argued that further progress in knowledge of cell physiology and of the chemistry of nutrition would lead to a prolongation of human life. A plea for periodic medical examinations of healthy people was made by Dr. Franklin H. Martin. He suggested that these examinations be made in the "standardised" hospitals of the United States, of which there are now some 1800. "Each hospital," he proposed, "volunteering to establish such facilities will be accredited as conducting a health inventorium." This scheme is being given careful consideration by the American College of Surgeons, of which Dr. Martin is Director-General. In a lecture upon a similar subject, Dr. Guy L. Kiefer said that certain life insurance companies were instituting regular medical examinations of its policyholders, the consequent lengthening of whose lives resulted in increased profits for the companies. And "a recent legislation Act in Michigan requires the physical examination of persons driving motor vehicles carrying passengers for hire. This brings another large group of persons into the ever-increasing orbit of periodic health examinations." Similar views were expressed by Dr. Eugene Fisk and Dr. James Glover. Proposals favouring the "positive" aspect of eugenics—implied in encouraging the fertility of the well-endowed—were limited to suggestions with regard to immigration. Upon this subject, again, there was division of opinion. Prof. East suggested that stricter medical examinations should be instituted in the "emigrating" countries of Europe with a view to excluding more effectively than is now done physically inadequate or defective types. Dr. Harry E. Hull, Commissioner-General of Immigration, held that Americans should encourage the immigration of "those Nordic strains of Northern Europe which in culture and rich heritage of tradition, contributed the most desirable material to our national structure." But Prof. Ales Hrdlicka expressed his disapproval of this partiality for Nordic strains in the following words: "In the last 15 years have been heard many alarms of the threatening deterioration of American stocks through the influx of the so-called 'inferior races' of white derivation. These threats have received no scientific foundation."

Nutrition.

A considerable amount of attention was accorded to this subject during the conference. By Dr. Arthur I. Kendall, dean of biology, Northwestern Medical School, it was argued that by the elaborate culinary preparation of foods were destroyed many strains of comparatively unresistant lactic acid-forming organisms which, in the human alimentary tract, oppose the multiplication of maleficent spore-forming organisms. Many resistant and pathogenic bacteria of this group were capable, as sole occupants of the alimentary tract, of seriously disturbing the normal "man-microbe balance." Several speakers stressed the plea, now reverberating through this country, for the consumption of more milk, wholemeal bread, fresh fruits, and green vegetables. Dr. Adolphus Knopf attributed the relatively high incidence of pulmonary tuberculosis among young women between the ages of 15 and 30 years to self-imposed habits of underclothing and under-nourishment which are inspired by a feminine fashion favouring a boyish appearance and figure. And Prof. Louis Howburgh warned his hearers against partaking of diets too rich in proteins. Diets, he said, containing 10 per cent. of tryptophane and cystine, were capable, in one week, of killing rats, in which were found at post-mortem, extensive hepatic lesions.

Popular Science.

Numerous miscellaneous addresses were delivered. Of these one deserves notice as illustrating a defect which inevitably creeps into popular semi-scientific conferences. The organisers of these conferences naturally strive to secure the support of eminent scientific men. Now the value to science of a given piece of research is by no means commensurate with its capacity to yield generalisations of popular interest. Having consented to make a contribution to the conference out of sympathy with its general aims, the scientific worker finds himself placed between the Scylla of delivering an address totally unintelligible to the bulk of his audience, and the Charybdis of having to distil from his theme, by some means or other, an argument relevant to existing social conditions. That this process of distillation may sometimes be somewhat forced was indicated, at the conference, by an address from Dr. W. N. Boldyreff upon "Some New Physiological Data as a Basis for Moral Hygiene." From the fact that "all vital phenomena should be classed under one of two groups—(1) useful or pleasant process, and (2) harmful or unpleasant processes," Dr. Boldyreff deduces the conclusion that "*temperance* should be the basis of our behaviour." Thus, at semi-scientific conferences with social aims, are "physiological data" stretched upon the Procrustean bed of popular demand.

Medical Practice by the Qualified and Unqualified

AFTER being before the House of Assembly for 11 years with various alterations and amendments the Medical, Dental and Pharmacy Bill has at last passed its third reading and been transmitted to the Senate, so that there is every prospect of it being placed on the Statute Book this year. Last year Dr. Malan, Minister of the Interior, by sheer perseverance advanced the Bill as far as the committee stage before the House adjourned, and had disposed of 75 of its 97 clauses. Among those first 75 clauses were the most contentious, including those dealing with the faith-healers, chiropractors, dental mechanics, &c., who flourish exceedingly in this country. A number of Members from the Platteland had not only espoused their cause for many years, but at last these Members seem to have realised the futility of their arguments.

When the Bill was resumed in the committee stage last week Dr. Malan moved a new clause obviously designed to placate the Platteland. This was to the effect that—

1. No person registered under this Act shall himself or attempt to make or to recover, or shall enter into agreement or associate himself in any way with any person for the purpose of making or fixing excessive extortionate charges for any services rendered or for article supplied or to be supplied by him by virtue of so registered.

2. Unless the circumstances are such as to render impossible so to do, every person registered under this shall, before rendering any service by virtue of being registered, inform the person to whom the service is rendered, or the person in charge of such person, of the which he intends to charge therefor (*a*) when so requested by any person concerned; or (*b*) when such fee exceeds that usually charged for the service.

3. Any registered person who contravenes or fails comply with any provision of this section shall be guilty of improper or disgraceful conduct within the meaning Chapter iv. of this Act, and it shall be the duty of the Council or the Board to take cognisance of and deal with such conduct under that Chapter.

Dr. Malan declared that the object of the Bill was not merely to place registered persons in a privi-

sition; its object was also, and principally so, to otect the public, and for that reason the amend- nt proposed aimed at preventing registered persons m charging exorbitant fees. The Medical Associa- n and prominent doctors had asked that the ond provision, quoted above, should be inserted the Bill. Several Members of the Opposition, wever, considered that it was a slight on the medical ofession, and a mere sop to the country Members, ose complaint last year was that the farmers are ng robbed by the doctors. Others maintained that, hough the standard of the medical profession in th Africa is admittedly high, there are exceptions, l that the provision is really intended to meet the e of those exceptional doctors who charge extor- nate fees. It was asked, "Who was to determine en a fee exceeded the fee usually charged?" and Minister replied that anybody who complained t the charges in any particular case were extor- nate could go to the court, and the court would rn a finding based on the usual charges in such es, as ascertained from the evidence of professional n of standing. It would be easier, however, if the lical Council as provided for in the amendment e put in a position to take cognisance of charges erally. The amendment was carried by 58 votes 31.

nother controversial point was a new clause uiring that in any case in which a patient dies r the administration of chloroform, the magistrate he district should hold an inquiry. It is difficult see the necessity for the clause, because under mon law there must be an inquest in all such es. However, the clause was adopted, Dr. Malan erving that although it was not perhaps necessary, ould do no harm.

question was raised concerning native men and nen herbalists in Zululand who had been licensed many years, and it was urged that the native ulation ought not to be deprived of such treat- nt, because often they had nothing else and could afford to pay for anything else. Dr. Malan arked that 2000 of these herbalists had been stered in Natal, or more than all the white doctors he country; yet there were none registered in Transkei, which seemed to manage very well out registration. He agreed that apart from native practitioners the natives had nothing. Government had, however, appointed a Commis- to go into the whole question of medical facilities natives, and he hoped something would come of it. he final hurdle to be cleared was an amendment behalf of dental mechanics, moving that nothing he relevant clause should debar them from prac- s which they had legitimately carried on in the . Dr. Malan declined to be shaken on this point, ving that the Select Committee had fully investi- d the whole question and had been practically nimous. The dental mechanic, he said, who ed to have the right to supply teeth on casts e by patients, had really been evading the law he past, and did not deserve consideration in the ent. The House adopted this view by an over- lming majority. The Bill as amended was oted, read a third time, and transmitted to the ate.

(FROM OUR OWN CORRESPONDENT.)

Practice of Dentistry by Medical Men.

HE Dentists Bill was under consideration in the last week in the Committee stage. It had ergone several changes since it was introduced a ago. The most important of these was the omission he clause prohibiting the practice of dentistry by ical men qualified after the passing of the Act. Bill as it now came before the Dail provided that ibitions of the practice of dentistry or dental ery should not operate in the case of registered medical practitioners. Much to the surprise of the members of the Dail the Minister in charge of the Bill (Mr. McGilligan) proposed an amendment to this clause which would in effect have restored the original prohibition, though slightly modified. His amendment provided that a duly qualified medical practitioner who became qualified after the passing of the Act might practise dentistry and dental surgery to such an extent as was incidental to his practice as a medical practitioner, but not otherwise. The amendment was opposed by all the medical deputies present, and by many members in all parts of the House, and was defeated by a majority of 78 to 50. The opposition was based on several grounds. It was pointed out that there had been no case made for interfering prejudicially with the present privilege of medical men; that the question of defining what was incidental to medical practice would be a matter of much difficulty; that obstacles would thereby be placed in the way of dispensary medical officers giving necessary dental relief to the poor. Sir James Craig made a further point in suggesting that to limit the present privileges of medical practitioners in the Irish Free State would prejudice the agreement as to reciprocity in medical practice made between the British and Irish Governments. In his reply Mr. McGilligan combated this view, stating that reciprocity meant no more than that there would be no distinction between a medical man qualified in England and one qualified in Ireland. On the general question of the right of the medical man to practise dentistry, he stated definitely that it was his wish to deprive medical men of the large powers they held under the Bill in the practice of dentistry. Dental surgery had, he said, become a recognised profession, and it was time its position was made clear.

Mr. McGilligan carried another amendment dealing with the method of erasure from the register because of misconduct. Under the Bill the Dental Board should make investigations and report the result to the Medical Council, with whom would lie the decision to erase a name. The Minister's amendment removes from the clause all reference to the Medical Council, and leaves the decision as to erasure with the Dental Board. By another amendment the Minister removed from the Bill the minimum penalty (£50) for the practice of dentistry by an unqualified person, leaving the minimum to be fixed by the justice in each case.

Results of B.C.G. Vaccination.

AN article by Prof. A. Calmette in the current issue of the *Bulletin*[1] of the International Union against Tuberculosis summarises the results obtained with the B.C.G. vaccine in protecting new-born infants against tuberculosis, from July 1st, 1924 (when the Pasteur Institute first placed the vaccine at the disposal of physicians and public health authorities), up to Dec. 1st, 1927. During this period 52,772 children in Paris and the provinces were vaccinated at birth with B.C.G. vaccine. 6219 were recorded as having tuberculous mothers or as living in tubercle-infected surroundings, and Calmette has followed up 5749 of these cases, the remainder being under the supervision of the health authorities in the Seine Inférieure, who have reported on them separately. Of the 5749 reported upon by Calmette, 3808 were vaccinated less than a year before Dec. 1st, 1927. At that date 118 deaths had been recorded amongst them, an infant mortality-rate of 3·1 per cent. The infant mortality-rate among non-vaccinated children in France is 8·5 per cent. The number of deaths presumably due to tuberculosis was 34, or 0·9 per cent., whereas the rate for non-vaccinated children exposed to tuberculous contacts varied from 24 to

[1] January, 1928. Paris: Secretariat of the Union, 2, Avenue Velasquez.

70 per cent. in France. Another 1941 children vaccinated between July 1st, 1924, and Dec. 1st, 1926, were aged between 1 and 3½ at the time of this report. Twenty-one deaths had been recorded in this age-group, of which four were presumed to be from tuberculosis. The general death-rate among them was therefore 1·2 per cent., compared with 1·6 per cent. for non-vaccinated children in the age-group 1–4, living in either healthy or infected surroundings. The tuberculosis death-rate was 0·2 per cent. On Dec. 1st, 1927, 917 of these children were between the ages of 2 and 3½. No death from tuberculosis had occurred among this group. 298 of them had been revaccinated at the end of their first year, but Calmette is doubtful whether this is really necessary. It now seems probable that immunity lasts longer than was at first thought. Observations on those children vaccinated by Weill-Hallé and Turpin in 1921 and 1922 and living in tuberculous surroundings, point to an immunity of at least five years' duration. This, Calmette considers, disposes definitely of the fear that the bacilli might recover their virulence and demonstrates the harmlessness of the vaccination with B.C.G. vaccine.

The statistics furnished by the Department of the Seine Inférieure are particularly interesting as this department has always had high infant mortality and tuberculosis death-rates. From Dec. 1st, 1924, to Dec. 1st, 1927, 1369 children were vaccinated at birth with B.C.G. There were 93 deaths under 1 year of age from general causes, of which 7 were presumably from tuberculosis. This gives an infant mortality-rate of 6·7 per cent. in the vaccinated group, compared with 13·4 for the department, and a tuberculosis death-rate of 0·5 per cent., compared with 8 per cent. for the age-group 0–1 year. 402 children specially noted as being in an infected environment were aged between 1 and 3 years on Dec. 1st, 1927. Only one death, from Pott's disease at the age of 17 months, was recorded among this group exposed to infection.

Disalbuminised Serums against Diphtheria and Tetanus.

The disalbuminised sera which the Pasteur Institute are now preparing according to Ramon's technique have some important advantages over the ordinary antitetanic and antidiphtheritic sera. These are that the quantity of the active substances injected (antitoxin) can be rendered more precise, that a large quantity of antitoxin can be injected in a very small bulk, and that there is a reduction in the frequency and intensity of serum reactions. The principle is as follows: the antitoxin is precipitated by the toxin; the precipitated element is centrifuged; the toxin and antitoxin are broken up by means of a weak acid, and finally the toxin is destroyed by subjecting the mixture to a temperature of 60° C., which leaves the antitoxin intact. The new sera have given good results from the point of view of cure, but they are particularly valuable for the prevention of diphtheria and tetanus. Experience with them affords us only matter for congratulation, since we no longer see those forms of serum sickness which so often followed injection and laid our patients low for several days.

Pre-operative Inoculation against Sepsis.

Except in cases where immediate operation is called for, surgeons in this country frequently prepare the ground, and increase the resistance of the patient by the use of vaccines. If the operation is septic, propidon is often used; it is a polyvalent stock vaccine, which has only one defect—namely, that it provokes reactions, not dangerous but somewhat violent. The same preparation may also be employed for aseptic operations, but where these involve the abdomen it is perhaps better to use autogenous vaccines made from the patient's own intestinal organisms. A drawback to these is the length of time required before immunisation is begun, and attempts are being made to prepare stock vaccines which will be equally effective in warding off sep due to bacterial invasion from the intestine.

The fashion of wearing short skirts, open shoes a silk stockings is responsible for the appearance o special form of erythrocyanosis, in which large pur indurated lesions are seen around and above t ankle, being especially noticeable towards eveni This form of erythrocyanosis must be related to t acrocyanoses; it is due to neuro-vasculo-humo disturbance, and is brought into evidence by co It seems to have some connexion with endocr disorders, either hypothyroidism (Leopold Lévi) ovarian deficiency (Maranon).

Favourable results with endocrine treatment ha been noted in a case of acrocyanosis in a man wh left hand was purple and swollen, and who h violent pains in the feet, which had been frost-bit during the war. A few injections of testicular extr caused the swelling to disappear, whilst the cyano diminished, and pain ended. This extract seems have a profound effect on disturbances of a nerv origin, though it can hardly be concluded that th acrocyanoses are due to orchitic insufficiency.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Decrease of Goitre in Vienna.

Prof. Wagner-Jauregg (the latest recipient of Nobel Prize for medicine) recently read a v interesting paper before the Vienna Medical Soc on the effects of the campaign against goitre. Ac on his advice the Austrian Government issued in 1 for public sale specially prepared salt contain 5 mg. of iodide per kilogramme of sodium chlor The assumption was that every person consumes d on the average 10 g. of salt, so that his daily intak iodine would amount to 5/100 mg. It has appea however, that the actual intake amounts only 3/100 mg., because less than 10 g. are taken da Prof. Wagner-Jauregg lays stress on the fact prophylaxis, to be effective, must extend its ac not only to the patient, but also to parents or a to their germinal cells, for in districts where goit endemic even the newborn are subject to it. Furt more, prophylaxis should extend to the whole pop tion, the Swiss method of giving iodine to sch children not being reliable, as many affected per escape the treatment. A systematic investigation o school-children in Austria was instituted in 1923, v the iodised salt was issued to the population. children were classified according to whether goitre was absent, beginning or slight, manifes pronounced. In Vienna there were at that 65,766 boys and 66,724 girls between 6 and 14 y of age in the public schools. In 1927 the figures w 51,853 boys, 53,275 girls. In 1923 57 per cent. without goitre, but in 1927 69 per cent. between ages of 6 and 10 were free and 56·6 per cent. betw the ages of 10 and 14. The manifest cases in numbered 1·6 per cent. and in 1927 0·16 per cen children of 6–10 years; the figures for the age-g 10–14 years were 2·5 per cent. and 0·43 per respectively. This drop to a tenth of the original f amongst the younger children, or a sixth amongs older ones, can only be ascribed to the constant u the iodised salt (called here Vollsalz=full-salt). the group of commencing goitres the decrease is so marked (from 30·9 per cent. to 27·1 per cent.

A second remarkable fact is the drop in the nu of operations performed for this condition. In 1308 patients in Vienna underwent a goitre opera in 1927 the figure had fallen to 806 cases (40 per less). In the province of Lower Austria the fi were 152, against 123 (20 per cent. less). These show that the systematic use of "full-salt" is beneficial in suppressing the spread of endemic g There is also reason to believe that its use is a

ange an existing swelling from a "manifest" or pronounced" goitre to "slight" or "beginning" itre. At present only 43 per cent. of the Viennese pulation are taking the medicated salt continually their own accord, but all public institutions, spitals, asylums, prisons, charitable institutes, and phanages also use it, so that about 55 per cent. y be reckoned as definite "iodine eaters." Until w no convincing proof could be produced that the ake of iodine by parents renders their offspring e from goitre, but the fact that goitre is rather rare ongst the school-children of the lowest standards, o are coming to school this year, seems to point in s direction and will be thoroughly investigated.

Public Health Statistics for 1926.

In Vienna, with its population of 1,890,000 souls, re die on an average 70 persons daily, of whom ht are cremated and the remainder buried. The al in 1926 was 25,807 deaths (of which number 91 were cremated). There were only 23,078 live ths or, in other words, the loss of lives was over 0, and in 1927 this loss increased; in the first half he year it was 1800, and it was nearly double that 1926 at the end of the year (full figures are not yet lished). Analysis of the figures shows that the nber of deaths is fairly stationary, but the number irths is constantly diminishing. 1300 persons died suicide last year; 5277, or over 20 per cent. of the al number, succumbed to diseases of the heart and ulation; 3822 died from tuberculosis, and 3261 m neoplastic disease, while 2386 were victims of umonia. No fatal case of cholera, typhus, or all-pox has been seen in Vienna for three years, or Austria for two years. The increase in the number new growths and cardiovascular diseases is noted over the country; they account for some 25 per t. of all deaths, and are a source of great anxiety the public health officers. The number of medical ctitioners in Vienna in 1926 was 4375; in 1927 ad risen to 4430. Amongst them were 396 females. re are 3·5 medical men on an average per 1000 of population or 3·8 female doctors per 10,000 nnese women. The Krankenkassa have appointed women doctors for female members who refuse be examined by a medical man. The public bulance (first-aid society) intervened in 26,246 cases year, or 16 per cent. more than in the previous r. The number of attempted—or committed—ides amounted to 1916 cases, or, in other words, ry thousandth Viennese citizen tried to destroy iself last year. 311 persons suffered injuries in ne kind of athletics or sport and 456 persons had to treated owing to intoxication with alcohol, whilst 8 accident cases and 811 persons who collapsed in streets or elsewhere required the help of the bulance. Out of 130,878 births in the Republic Austria 3956 were stillbirths. In 124,160 cases lified or trained helpers were present; the remain-6218 births took place without doctor or midwife. illegitimate births in the Republic amounted to 245, or 27 per cent.

Dr. Doppler's Method of Producing Hyperæmia in Circumscribed Regions.

Public attention, as well as the interest of medical n, has been concentrated lately upon a method ised by Dr. Doppler, first assistant to the well-wn surgeon, Prof. Lorenz, which aims at producing improved function of glandular organs by causing fuse hyperæmia through dilatation of the afferent eries. Dr. Doppler observed three years ago that destroying certain branches of the sympathetic a ked hyperæmia could be obtained. He used this hod in a case of gastric ulcer after partial resection he stomach. The favourable result prompted him ise the method systematically in operations on the nach to prevent the formation of peptic ulcer so n observed after surgical interference. He painted appropriate arteries with a 7 per cent. aqueous tion of carbolic acid, which is sufficient to destroy the vaso-constrictors, whilst the vaso-dilators are not affected. The arteries appear permanently dilated, the organs become extremely hyperæmic, and their activity is increased. No evil results have been noted. Dr. Doppler is not prepared to say how long the effect will last. In his recent paper, read before the Vienna Medical Society, he spoke only of "reactivation of the entire organism" or certain parts of it which follows the "phenolisation" of the testicles (spermatic artery) or ovaries (art. ovarica), and did not speak of "rejuvenation." The methods of Steinach and Voronoff aim solely at increasing the function of the sexual glands. Doppler, however, recommends his method for the purpose of "reactivating" other organs also, especially the pancreas (in diabetic conditions). In a series of animal experiments in the Vienna Veterinary Physiological Institute Prof. Schwarz showed that the disturbed function of the pancreas can be permanently corrected by an increased supply of arterial blood. His method is based physiologically on the experiments of Dr. Leriche (Paris), who severed the sympathetic on the femoral artery; but there the dilators were also destroyed. More than 200 patients have now been treated by the new method, sometimes with wonderful results. Reports have been received that pyorrhœa disappears rapidly after Doppler's "phenolisation," and psychic disturbances have been beneficially influenced. If his observations and those of the clinic of Prof. Lorenz can be corroborated the ultimate results of this apparently modest addition to medical science may be incalculable.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 18TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 369 (same last week); scarlet fever, 1871; diphtheria, 1472; enteric fever, 57; pneumonia, 1602; puerperal fever, 52; puerperal pyrexia, 112; cerebro-spinal fever, 14; acute poliomyelitis, 8; acute polio-encephalitis, 2; encephalitis lethargica, 27; dysentery, 10; ophthalmia neonatorum, 111. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 23 counties:—London, 10 (Shoreditch 2, Southwark 7, City of Westminster 1); Bedford, 3 (Bedford); Chester, 1; Derby, 7; Durham, 93; Isle of Ely, 1 (Ely); Gloucester, 1 (Chipping Sodbury); Lancaster, 34; Lincoln, Parts of Kesteven 5, Parts of Lindsey 8; Norfolk, 4 (Norwich C.B.); Northampton, 1 (Northampton C.B.); Northumberland, 9; Nottingham, 19; Stafford, 17 (Stoke-on-Trent C.B., 2; Bromwich C.B., 1; Wolverhampton C.B., 2; Newcastle-under-Lyme, 12); Surrey, 2 (Guildford); Warwick, 2; Worcester, 1 (Redditch); Yorkshire, North Riding 15; West Riding 55; Brecknock, 6; Glamorgan, 30; Monmouth, 45.

The number of patients at the Infectious Hospitals of the Metropolitan Asylums Board on Feb. 21st–22nd was as follows:—Small-pox, 25 (6 of these being under observation); scarlet fever, 1737; diphtheria, 2599; enteric fever, 31; measles, 1440; whooping-cough, 181; puerperal fever, 18 (plus 16 babies); encephalitis lethargica, 76; poliomyelitis, 1; "other diseases," 34. At St. Margaret's Hospital there were 13 cases of marasmus and 13 babies (plus 10 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 89 (44) from measles, 9 (4) from scarlet fever, 30 (4) from whooping-cough, 42 (9) from diphtheria, 50 (7) from diarrhœa and enteritis under two years, and 83 (5) from influenza. The figures in parentheses are those for London itself. The deaths from enteric fever outside London occurred in Nottingham and Huddersfield. Of the 55 fatal cases of measles outside London 7 were reported from Plymouth, 6 from Bristol, 5 from West Ham, and 4 from Manchester. The number of stillbirths registered during the week was 294 in the great towns, including 62 in London.

Correspondence.

"Audi alteram partem."

EUGENICS AND A NATIONAL STOCK-TAKING.

To the Editor of THE LANCET.

SIR,—I should like to emphasise the suggestion in your valuable leading article last week under this heading that the time has now come for the medical profession to take a deeper interest in genetic problems, and to coöperate in a wisely considered movement to find out how we stand as a nation in regard to the physical and mental qualities of our citizens, and to help forward a sound movement for eugenic reform.

In 1906, in a discussion on the biological foundations of sociology, I made an appeal that systematic instruction in the science of heredity and its application to human life should be included in the medical curriculum. In the Galton Lecture last week I again tried to point out that not only would the study of genetics gain from the utilisation of the unrivalled opportunities possessed by medical men for observing and recording the hereditary transmission of normal and abnormal mental and bodily characters from parents to offspring, and from generation to generation, but that medical science and medical practice would also profit from the wider knowledge so obtained of the influence of "the hereditary factor in disease."

Every medical man who has seriously studied the problem of immunity, innate and acquired, must have sometimes wondered why so much more attention has been devoted in the past to the investigation of the innumerable varieties of pathogenic and non-pathogenic organisms of disease than to the biochemical processes and the cellular activities by which the body tries to repel or to recover from disease. There can be little doubt that a deeper study of both racial and cellular heredity, and of innate capacity of resistance, would throw valuable light on this latter problem. But in order to bring about this change in medical education, a more sympathetic outlook towards genetics must first be secured in the General Medical Council, in the medical faculties in our universities, and in our medical schools.

It is somewhat difficult to fully realise the great advantage which would accrue to our nation and race if our medical profession, general practitioners and professors of medicine, all possessed a sound knowledge of genetic science. Such knowledge would enable them to act as skilled advisers to their patients in matters of the utmost importance from the point of view not only of individual, but of national and racial welfare. Preventive medicine in the truer sense must also depend largely on the application of such genetic knowledge to human societies. Moreover, statesmen and legislators, Government departments, and education and health authorities would be greatly assisted in trying to improve the conditions of life for the people if they could rely upon some well-established scientific knowledge of a biological kind concerning the effect of their schemes on the racial qualities of our people.

It will, I think, be admitted that some at least of our economic regulations and sociological methods are not founded on sound biological principles. They do not look far enough into the future. They are concerned too exclusively with the interests of the individual (in some cases the low grade, degenerate individual), and not enough with the ultimate influence of such schemes on racial welfare. Then there is the great problem of conception control—the world-wide experiment now going on, so potent for good and harm.

If, as I said in the Galton Lecture, it be true that adequate knowledge of the factors which affect fecundity and of the means of controlling conception, when used in a right way, are necessary steps in t evolutionary process whereby man will be enab to exercise a growing influence over human desti and by which also the possibility of increasing racial stock of innate capacity will be brought wit human control, then surely it is the medical pr titioners of the country who ought to study this v and complex problem in all its aspects, in order t they may guide the citizens of all classes along li calculated to promote racial as well as individ and national welfare.

It is only possible in this short letter to indic one or two of the many problems which depe upon the application of genetic knowledge to natio life. The question of racial deterioration and possibility of arresting the process of decline is of increasing importance, and my main object in Galton Lecture was to point out that we should wise as a community to take stock of our positi and that we ought to try to find out in what gro or sections of the population, bodily, and especia mental qualities, intellectual and moral charact and capacity for citizenship, show any signs improvement or decay. The question of the dif ential birth-rate, and of the disastrous effect wh breeding from inferior and degenerate stocks, continued long enough, and on a sufficiently la scale, must exercise on the racial qualities of population, while of great national importance, also one in which the medical profession should deeply interested. Medical men must be especia concerned in advising their patients about important question of marriage from the euge point of view, and doctors, perhaps more intimat than others, are in a position to see the disastr effect of mental defect and other innate disabili and diseases which arise from, or which may accentuated by, the marriage of persons who are subjects of hereditary disease, or who come fr degenerate stocks.

In thanking you for your appreciative and criminating leading article, may I also express hope that it may lead to a wider interest in gen and eugenic problems on the part of the med profession in our own and other countries, and to the inclusion of some systematic instruction genetic principles in the medical curriculum.

I am, Sir, yours faithfully,

Leicester, Feb. 27th, 1928. C. J. BONI

TRANSPLEURAL EXPLORATION OF TH ŒSOPHAGUS.

To the Editor of THE LANCET.

SIR,—We should like to support the plea of Romanis and Mr. Neilson (THE LANCET, Feb. 2 p. 386) for transpleural exploration of the œsopha and to welcome the signs of coöperation between general surgeon and the laryngologist in the atte to secure earlier diagnosis of carcinoma. One o (A. T. E.) has used the artificial pneumoth method for exploring the thorax for the past five ye and in our experience also it is easy to expose c pletely all parts of the intrathoracic course of œsophagus. For the upper and middle parts easier approach is from the right side; for the lo from the left. Whilst it is quite possible to get g access without removing a rib, it is an advantag excise a very small segment of one, or possibly t behind the angle. Removal of a growth is a form able business even when feasible—our only case actual removal died within 12 hours of shock— given earlier diagnosis, and increased familiarity whole team with the operation, we believe that suc will sometimes be attained. Exploration as such be conducted with little if any more danger than exploratory laparotomy, and the route certai opens up possibilities for the more efficient use radium in the cases unsuited for removal.

We are, Sir, yours faithfully,

E. ROCK CARLING,

London, Feb. 28th, 1928. A. TUDOR EDWARD

THE EMPLOYMENT OF TUBERCULOUS PATIENTS.

To the Editor of THE LANCET.

SIR,—Dr. F. N. Kay Menzies's report on the nployment of tuberculous workers, which you mmarised in a recent issue,[1] will indeed have rformed a valuable service if it succeeds in attracting e attention of public bodies to the work being done this field. It is most difficult to impress laymen th the facts that tuberculosis is a fluctuating and fectious disease, and that it is far more dangerous health and home than any foreign enemy. In nsequence, and largely also because its outward and sible signs do not excite compassion, the public are mewhat apathetic about it, and quite fail to realise at "after-care" is indispensable to every form of e treatment of tuberculosis.

One of Dr. Menzies's points seems, however, to be en to question. He states that "a commercial dertaking employing tuberculous employees and ying a wage adequate for their maintenance cannot run without serious financial loss. . . ." The perience of Papworth does not bear this out. pworth industries are a commercial undertaking, ploying tuberculous employees and paying a wage equate to their maintenance, and the average net s per employee per annum, calculated over eight ars, is not more than £3 or £4. This is likely to be creased as the industries extend; and would almost appear if adequate capital were available. If this considered serious financial loss, there is only this be said: How much greater would the cost be if se persons left Papworth, spread the disease, broke wn and had to be readmitted for a further period sanatorium treatment? In point of fact, if one of m were readmitted for a fortnight to a sanatorium ould cost more than to employ him in the settlement a year; and if he infected any healthy person as ll the cost of *not* keeping him in a settlement would come enormous.

In these calculations no charge in respect of capital ncluded. If it were, however, the cost per employee uld be greatly reduced. It is reasonable, therefore, contend that public bodies would find an investment village settlements most valuable; for though it uld yield no interest, it would save them large sums sanatorium charges on readmitted cases and pay idends of happiness to their beneficiaries. This er point is, I think, of some importance, though cannot be brought, unfortunately, into the scale inst pounds, shillings, and pence.

I am, Sir, yours faithfully,
P. C. VARRIER-JONES.

apworth Hall, Cambridge, Feb. 22nd, 1928.

PREVENTION OF DIPHTHERIA.

To the Editor of THE LANCET.

IR,—Dr. Massingham's letter in your issue of . 25th rightly records facts of much importance egards the validity of the Schick test, which await uture explanation and that suggested "further arch," to account for what are apparent "border- " anomalies in the rare instances of the reported rrence of clinical diphtheria in Schick-negative viduals, if indubitable and authenticated, as cases quoted are seemingly claimed to be. The ject finds reference in the Medical Research ncil's report on the "Prevention of Diphtheria," lished last May, and at the risk of trespass on r valuable space, quotation of a paragraph on e 15 headed "Occurrence of Diphtheria in the ick Negative," would seem appropriate.

view of a certain, if small, number of instances in h an apparently genuine Schick-negative reactor has reported to have contracted diphtheria, it would seem ssary to assume that the amount of antitoxin present—in the circulating blood—at any given time does not esent a fixed and unchanging quantity, but that varia- in *some* individuals may occur, and that in such cases contact with a massive diphtheria infection may be sufficient to upset the finely balanced defensive mechanism and to give rise to an attack of clinical diphtheria, though one usually modified in character. Such cases as have been reported require very careful and critical study before the diagnosis can be accepted as correct; first, as regards accuracy of technique and reading of the result of the Schick test; secondly, with reference to the clinical and bacteriological condition notified as diphtheria; and, thirdly, as to the antitoxin content of the patient's blood. The possibility of a carrier condition of diphtheria bacilli and supervening tonsillitis, due to some other organism, might well account for a case being notified as diphtheria, and so by casting suspicion on the true value of the test, lead to an imputation of fallacy. Whatever the explanation may be, however, the facts for and against suggested fallacy demand the strictest inquiry and unbiassed interpretation.

Further on reference is made to a few conflicting results quoted by Dr. B. A. Peters[1] in 1922 at Bristol, who pointed out then the possibility of fallacies as to the interpretation of the test, but at a later date suggested that although a Schick-negative result always indicated a comparatively high immunity, under the exceptional circumstances of exposure of fever hospital staff to virulent infection in massive doses, the negative response might not *always* mean *complete* clinical immunity.

Dr. E. H. R. Harries,[2] with his wide experience of the value of the Schick test, also recently made reference to similar cases (in a paper read before the Epidemiological Section of the Royal Society of Medicine, Nov. 25th, 1927) and was of opinion that they were instances of "diphtheria tonsillitis" in an immune, and that although following infection a membrane was visible on the fauces, it always presented the same characteristics, was very thin and easily stripped without leaving a bleeding surface—separating spontaneously to leave the fauces apparently normal—such cases never suffered from the toxæmia of diphtheria nor required antitoxin, as the faucial infection, acting as a secondary stimulus, very rapidly raised the antitoxic titre of the blood. To this category Dr. Massingham's cases very possibly belong.

I am, Sir, yours faithfully,
J. GRAHAM FORBES.

County Hall, S.E., Feb. 27th, 1928.

[1] THE LANCET, Feb. 4th, p. 246.

GASTRO-DUODENAL ULCERATION.

To the Editor of THE LANCET.

SIR,—In view of the convincing letters you have published from Dr. J. A. Ryle and Dr. T. Izod Bennett I had not intended to join in the discussion on this subject, but as Dr. A. J. D. Cameron suggests in your issue of Feb. 25th that Prof. MacLean was the first in this country to write on the intensive alkaline treatment of ulcer, I should like to draw his attention to a paper of mine on the Pathology, Diagnosis and Treatment of Gastric and Duodenal Ulcer, which appeared in the *British Medical Journal* of April 24th, 1920. I there stated that in common with many other physicians I had given alkalis for many years, but that after a visit to Sippy's Chicago clinic in July, 1919, I had used a modified form of his ntensive treatment, which I proceeded to describe in detail.

Three years later, in June, 1923, at about the time Prof. MacLean says he first gave alkalis to patients with ulcer, I had reason to believe that the treatment was already so widely used by practitioners throughout the country that I thought it right to publish in *The Lancet* and *British Medical Journal* a warning as to the danger of toxic symptoms. So far from being a "bogy which need not be feared," as MacLean and his colleagues state, alkalosis is a very real danger, especially in patients with any gastric stasis or with renal insufficiency, which may be so insignificent that it can only be recognised by estimating the blood-urea. I have seen one fatal case and several others have been reported. My colleague, Dr. J. F. Venables, described a series of severe cases of

[1] THE LANCET, 1923, ii., 784; and 1924, i., 821.
[2] Proc. Roy. Soc. Med., Dec., 1927, p. 197 and p. 210.

alkalosis following alkaline treatment of ulcer in the *Guy's Hospital Reports* for 1925. For some reason the condition has in my experience only occurred in private patients, which may account for the fact that Prof. MacLean has not observed it in his hospital unit, but it is none the less important for the practitioner to recognise the first signs of alkalosis so that the treatment may be discontinued without delay.

The correct dosage of alkalis is a very complicated physicochemical and biochemical problem, which is at present the subject of active investigation at Guy's Hospital. The value of the mixture recommended by MacLean is entirely due to the sodium bicarbonate and magnesium carbonate it contains, as the work of Mr. E. Matthews, which will be shortly published in our *Reports*, shows that bismuth carbonate is almost completely devoid of neutralising power. On the other hand, the 10 grains of sodium citrate, which MacLean, in common with most physicians, gives with each feed in order to prevent coagulation of the milk, has almost the same neutralising power as the 12 grains of sodium bicarbonate he gives every two hours.

Prof. MacLean writes, in reference to infected teeth, that "unless we are misinformed with regard to the general attitude of the profession on the subject, there is at present little risk of the teeth, septic or otherwise, being overlooked." From my experience I should say that he certainly has been misinformed, as out of 126 consecutive cases of duodenal ulcer at New Lodge Clinic 25 per cent. had well-marked pyorrhœa alone, 9 per cent. had apical infection alone, 40 per cent. had both, 8 per cent. were edentulous, and only 18 per cent. had healthy teeth. The corresponding figures for 30 cases of gastric ulcer were 23, 20, 21, 13, and 23 per cent. respectively.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Feb. 27th, 1928

MASTOID OPERATIONS.

To the Editor of THE LANCET.

SIR,—It is interesting to read in your current issue Sir Charles Ballance's retrospect. Doubtless he looked back and was influenced by his teachers when he designed his own operation. His, like theirs, seems to attract little attention in these days. On the other hand, I looked forward and was not at all influenced by the work of my predecessors when designing my method of operation, because I had learnt a great deal by observing Nature's attempts to cure mastoid disease, and based my technique on these.

Dr. Percy Jakins, of the Central London Ear and Throat Hospital, was the first surgeon to visit the Throat Hospital to see me perform one of these operations. He made this remark in the operating theatre: "Your operation will take the place of all Schwartze operations and most of Stacke's radical ones." Evidence of the soundness of his opinion was forthcoming last week, for on the 23rd inst. I performed one of these operations, exhibited a cured patient, and subsequently lectured on Diagnosis in Mastoid Disease at the Burton-on-Trent Hospital by invitation of the local Medico-Chirurgical Society. There I was informed that 76 mastoid operations had been performed in the hospital in the past year, that 74 of these were carried out by my method, and two by Stacke's (radical) method—the radical measure being adopted on account of the presence of cholesteatoma in the attic.

I may mention that many aural surgeons have informed me that they perform no mastoid operations except by my method; I hope, before long, that all large towns will be competent to deal with the ear diseases that occur in them.

I am, Sir, yours faithfully,

CHARLES J. HEATH.

Devonshire-place, W., Feb. 27th, 1928.

THREE CONCEPTIONS OF TUBERCULOSIS

To the Editor of THE LANCET.

SIR,—In his kindly criticism of my paper in you issue of Feb. 4th (p. 259), Dr. Blanford takes the vie that whenever symptoms and signs suggestive pulmonary tuberculosis are present the disease serious; the outcome cannot be foretold, an sanatorium treatment should be advised; but wit efficient medical examination this means sendi 30 to 40 per cent. of the population to sanatoria some time in their lives, most of whom would recov just as well at home. To-day the great majorit of these cases recover undiagnosed, there may suspicions in the practitioner's mind, but he hesitat to name the complaint until an exact diagnosis ca be made, which sometimes means that the disea is no longer "minor." In this way special treatme may be dangerously delayed in low-resistant patient If the real frequency of symptoms due to tuberculos were generally realised this diagnosis would be muc more common, based it is true on ground less su than at present, though just as scientific as mo other diagnoses in general practice. There wou then, I think, be more observation, people in tin would be less apprehensive, and special treatme more readily adopted.

An acute case is unsuitable for the sanatorium. is the border-line case with some resistance, but n doing well at home, that will benefit there, an nothing is lost for such patients by three month observation and treatment at home. There are, course, certain conditions which make immedia sanatorium treatment advisable:—

1. A positive sputum.
2. A bad family history.
3. Very bad surroundings.
4. Patient has not improved with home treatmen

The constant iteration that early cases must sent at once to a sanatorium has led to a false positio Some minor cases are sent there unnecessarily (so to be returned with the diagnosis unconfirmed), a in other instances the supposed necessity for such step dangerously delays the diagnosis. In deali with tuberculosis, the point where medical experien and skill are of the highest value is not so much making a diagnosis, but in deciding what should done for the individual patient. If the mere existen of tuberculosis necessitated sanatorium the matt would be simple, and the recent innovation of appoi ing junior men to act as school medical officer, welfa officer, assistant medical officer of health, *and tuberc losis officer* would be justified; but the matter is n so simple, and a lifetime is not too long to learn h to treat the individual patient.

The experience of the sanatorium officer is like to be wider, and his advice more sound, in deali with major tuberculosis, but the tuberculosis offi has the advantage in advising about tuberculosis met with in everyday practice.

I am, Sir, yours faithfully,

Paignton, Devon, Feb. 21st, 1928. E. WARD.

INCIDENCE OF THE MINOR PSYCHOSES.

To the Editor of THE LANCET.

SIR,—The views of Dr. T. A. Ross and mys are so much in accord that I can treat his letter your issue of Feb. 25th only as an opportunity defining my position when I challenge the curre usage of words like "neurosis." I am in agreeme with him as to the important difference between t groups that I call major and minor psychoses, a also as to the need for using words that our patien and their friends, will not misunderstand. I reg that the word "benign" did not occur to me inste of "minor," which was suggested by the Fren *petits mentaux*.

In talking to patients I have, like him, to acc their distinction between "nervous" and "menta and this distinction would be useful and harml if it were recognised that, like hysteria, some of th

rds do not mean what they appear to mean. The tory of neurosis, as shown by quotations in the ford English Dictionary, indicates a perversion of aning that has resulted in perversion of thinking. ginally it meant an interference with physiological ve function; lead colic was a neurosis, and a ter speaks of the functional disorders as including euroses, hæmorrhages, and dropsies." Then in 'seventies philosophical speculation led to the inition of a neurosis as "a change in the nerve ls of the brain prior to and resulting in psychic ivity," and this metaphysical conception became ked with clinical use so that we find Maudsley iting of "insanity, epilepsy, and other neuroses." ere was no objection to this use of the word as pressing the idea of one aspect of a condition or ion, the other aspect being the psychosis, so long it was not confused with the older meaning. It plied the axiom "no psychosis without neurosis." Now, however, obverse and reverse have become arate coins, and paranoia is a psychosis whilst obsessional state is a neurosis; I do not know y, and I do not think anyone else knows. To ny of us the label "neurosis" indicates a histo- hology, some change in nerve towards the discovery which our efforts should be directed. But our rts are not so directed. When my attention was ned to the study of miner's nystagmus—now ting us half a million a year—I could find no ord of any pathological investigation of that upational neurosis. The word is apparently not timulus to such investigation. On the other hand, loes serve the purpose of enabling us to turn aside m the psychological study of conditions which, my belief and the belief of Dr. Ross, can be use- ly approached by that route. Telegraphists' mp is called a neurosis and, until the investigation vas enabled to carry out for the Fatigue Board, iad no conception of the wealth of psychological terial that underlies the symptoms of that dis- er. Our text-books actually present students h speculations about the location of a lesion that ows one man to use the Morse key perfectly so g as it is attached to a recording tambour, but that ises cramp when he knows the key is attached to a graph wire; or allows another man to send ry combination of dots and dashes except those icating the hard-sounding letters C, K, and Q; produces painful cramp in another as soon as he down in the position of sending. Our connota- n of the word neurosis directly encourages the scription of *Linimentum saponis* for these vagaries behaviour.

These remarks apply to all those words, even the rd nervous, that imply a non-existent pathology. ewhere I have quoted approvingly the phrase of Johnson in a letter to Mrs. Thrale: "A tender, table, and, as it is not very properly called, a vous constitution." Dr. Ross has written an mirable book called "The Comm on Neuros s"; I ve written a book called "The Nervous Patient." ertainly bowed to custom in my choice of title, I probably Dr. Ross did likewise; my only claim superiority is that my idol was older than his.

This attack upon nomenclature is not in the interests inguistic purity, but is an effort to induce a more pful attitude towards what I shall still call, when rammelled by custom, the benign or minor choses. The word neurosis should be restored its original meaning; there is need for it in sifying such disturbances as hysterical dermato- phia, mucous colitis, some dyspepsias, tachy- dias and asthmas, where it may be convenient to sider them as disturbances of the physiological ction of nerve tissue.

n only one fact of observation do I find myself ering from Dr. Ross. Fear of the dark in childhood ot universal; I know intimately one child who er suffered from it and was perplexed and annoyed discovering it in a playmate.

I am, Sir, yours faithfully,

ondon, Feb. 27th, 1928. MILLAIS CULPIN.

CARBON DIOXIDE IN ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—Dr. Birt's letter in your last issue reaches conclusions regarding carbon dioxide in anæsthesia which are at variance with my experience. During three years I have used carbon dioxide in anæsthesia for some hundreds of major and minor operations in infants, children, and adults, and I regard it as a very important part of the anæsthetist's equipment. I invariably use a sight-feed bottle, usually a triple one (made by Coxeter), and with it I have complete control of the gas as well as considerable accuracy in its percentage, and very rarely has there been cause for the least anxiety in its administration. To be able to increase the respiratory excursion by means of a small percentage (1–5) of carbon dioxide and thus facilitate and hasten the induction of anæsthesia is of great importance, especially in infants and children whose tidal wave is relatively small. The benefit is not less apparent in adults where frequently preliminary morphia has depressed the respiratory centre. With carbon dioxide the great majority of such patients experience a rapid and easy induction of anæsthesia. In my[1] experience, except in old people, the rapid and complete elimination of the anæsthetic agent by means of carbon dioxide is a potent factor in convalescence.

I am, Sir, yours faithfully,

Aberdeen, Feb. 28th, 1928. J. ROSS MACKENZIE.

ULTRA-VIOLET RAYS AND VARICOSE ULCERS.

To the Editor of THE LANCET.

SIR,—In your report last week of a meeting at the Medical Society of London it appears (p. 392) that Dr. Heald, discussing recent claims that "varicose ulcers uniformly yielded to, and could be cured by, ultra-violet light," stated that Dr. Dora Colebrook, "following the exact technique of the man who made the claim," had met with complete failure. As several people, amongst them myself, have claimed that ultra-violet radiation was of value in the treatment of varicose ulcers, would it not have been more fair to have given the name of the man whose technique Dr. Colebrook followed? It would at least have given him an opportunity to reply. Moreover, to make a mystery of his identity is an unwelcome departure from the customary practice of giving references. There have been so many claims and denials as to the value of ultra-violet in the treatment of ulcers, that it would appear that the time has arrived for the subject to be given a full evening's discussion to itself. Hitherto it has but been mentioned in discussion on ultra-violet in general.

I am, Sir, yours faithfully,

London, W., Feb. 27th, 1928. M. WEINBREN.

[1] British Journal of Anæsthesia, October, 1926, p. 92.

MEDICAL PRACTITIONERS' UNION.—This Union held a dinner and dance at the New Princes' Galleries on Feb. 23rd. When the loyal toast had been honoured the health of the Union was proposed by Dr. Graham Little, who declared that the M.P.U. was fighting for some of the most important principles in medicine, and that in Parliament it was making history. The profession had at the present time a remarkable opportunity for usefulness to the community and for its own advancement and status, and it ought to be more united. Few doctors were willing to make the sacrifice of time, money, and effort necessary to hold seats in Parliament, but it was most important that they should be more adequately represented. Dr. E. A. Gregg, the President, in replying, said that he was more convinced to-day than ever of the need for his organisation, which was trying to do for doctors what no other professional organisation attempted. The M.P.U. wanted to emphasise first of all the doctor as doctor, and secondly to face the modern problems of the doctor's contact with the public at large. The health of the guests was proposed by Dr. G. de Swietochowski, and Sir William Arbuthnot Lane replied.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Health Insurance in Scotland.

On Thursday, Feb. 23rd, the House of Commons went into Committee of Supply on the Supplementary Civil Estimates, 1927, Captain Fitzroy in the chair.

On a supplementary estimate of £10 for the salaries and expenses of the Scottish Board of Health, including grants for National Health Insurance and other purposes,

Sir John Gilmour, Secretary of State for Scotland, said that since this matter had been very fully debated on the English supplementary estimate it would be unnecessary for him to go very fully into it. He would like to say, however, that it was a matter of very grave concern both to the approved societies and to the minister concerned that there should have been this very large increase in expenditure. The expenditure commenced to rise in 1926 very markedly after the stoppage in the coal industry and continued at an abnormally high rate until the end of 1926, necessitating a supplementary estimate in that year. It was expected that it would decline, but unfortunately that had not been the case. The expenditure on sickness and disablement benefit during 1927 was even heavier than in 1926. For example, after allowance for extra expenditure on additional benefits, if they took the index figure for 1925 as 100 the figure for 1926 was 113·5 and for 1927 117·75. It was very difficult to find any explanation of this high expenditure. Apart from an epidemic of influenza in March last year 1927 had not been an unhealthy year, whether it was judged by the mortality figures or by other standards such as the number of prescriptions issued by the medical practitioners in Scotland to their insured patients. It might be that those who had been out of work for some period through the long industrial depression might have sought this channel in increasing numbers to obtain relief. It was clear, too, that there was a great feeling of apprehension on the part both of the approved societies and those connected with them that the medical profession was not taking that amount of care in giving this relief that might be expected of them. Already the Scottish Board of Health had taken steps to call the attention of the approved societies to this huge increase and had been in consultation with the representatives of the medical profession. He would not say at that stage what steps in addition to those already taken could be taken to help in this matter, but it was clear that such steps as, for instance, not allowing the transfer of an applicant from one medical practitioner to another except within a certain period might have some slight effect. The period had already been increased and it might have to be further increased. In any case they would carefully watch these matters and in the long run, if there were flagrant examples of medical practitioners failing to carry out their duties reasonably, other steps would have to be taken. It was satisfactory that in asking for authority to meet this increased expenditure he was not asking the House for extra money. They had been able in the estimates which Parliament had already voted for his department to make certain savings upon the item of steel house construction. They had proceeded with 500 houses less than they intended, and it was proposed to transfer a portion of this saving to meet the extra expenditure under this vote which amounted to about £40,000.

Housing and Health.

Mr. James Stewart moved to reduce the vote by £5. He said that the need for houses was growing greater and greater in Scotland. There had been built from 1919 to the present time 67,000 houses, whereas in the nine years, at the rate of 20,000 houses per annum, there ought to have been built 180,000 houses. So the shortage had grown from 121,000 to nearly 230,000, not with an improved standard, but merely to keep things as they were. What was the use of increasing medical benefit, and spending more money in health administration when the problem which was the source of nearly all the troubles that beset them began in the house and ended in the house through the bad conditions which obtained? While it was true that their infantile death-rate this year was the second lowest in their history —namely, 82 against 79, their lowest—in other parts of the world, not more happily situated in regard to climate and other conditions than they were, the death-rate was ever so much lower. They were asked to accept that sort of thing as something with which they had got to be satisfied in spite of the tremendous development in medical science and the fact that their medical officers to their credit in every municipality in Scotland had year in and year out been drawing attention to the relationship between housing and health generally. In the densely populated quarters of Glasgow the infantile mortality-rate was three times the average for the city. In this way they were filling their hospitals and increasing their expenditure in every direct The Government must take a step forward to meet circumstances of the great industrial centres. In Glas over £600,000 had been spent annually on health admi tration of which a considerable proportion had to be by the city. This expenditure was ever growing, yet cause of it all was left practically untouched, nay, worse t untouched, for it was being allowed to develop int festering sore which was cutting off lives which could saved and which would perhaps be of great advantage to State in its hour of need, should that come again.

The Discretion of the Doctor.

Mr. Kidd said that there was only one point which m him a little suspicious of the Secretary for Scotland that was his reference to the extra cost incurred thro increased sickness. He would ask the right hon. gentle to remember that last year Scotland was still sufferin violent reaction from the coal stoppage, and incidentall had been the wettest season on record. The weather, ta in conjunction with the lowered vitality of the pe following the stoppage, readily accounted for the incre sickness. He would ask the Secretary for Scotland to slow to assume that medical practitioners in Scotland been a little too facile in allowing panel patients med treatment, or too slow in turning them off the list. ought seriously to hesitate before interfering with discretion of the doctor, because otherwise with whom the supervision to rest? Was the doctor to be superv entirely by official medical men representing the Minis or was he in order to support his case to have the assist of other panel doctors? He put that point the r anxiously because he had found cases where objection taken by a doctor to his being overridden on the questio the quality of the medicine he had prescribed. One did want to create the impression that there were two cl of patients, the patient who was on the panel and patient who was not, so far as the prescribing of medi was concerned. If they raised a question of that kind would bring the Insurance Act into disrespect and mal very suspect. The discretion of the panel doctor m not be exercised legitimately in every case, but he had h of it being challenged in the case of medical men w repute was beyond all doubt, and if they spread the that doctors had been slack they would start on a thorny p

Mr. Scrymgeour said he would like to know what evid there was in Scotland for this strange report concer medical men and the allegation that they were not pro looking after the interests of approved societies and funds through failure properly to supervise cases which c to them for treatment. There was a case in Dundee rece in regard to which the doctor according to his own expl tion to him (Mr. Scrymgeour) took very great care. doctor decided that a patient ought to be put off be because he conscientiously thought that she was abl resume work. As a matter of fact that was far from t the case, and the patient got worse. The doctor explained that if the patient had come back and said she could not manage to work he would have put her c benefit again. That was an instance which showed th doctor was over-careful in handling a case. He did think that there was any substantial ground for saying doctors were slack in attending either to the interests o patients or to those of the approved societies. If su state of things prevailed they would have very clear of it through representations made before the Insur Committee or to some of the approved societies.

Mr. Stephen said that the Secretary for Scotland ha evidence to show that the medical men in Scotland wer acting properly in this matter, and he hoped that House would think very seriously before they all the right hon. gentleman to impose new conditions o medical profession in order that doctors might be bu into sending people to work when they were unfit to v The increased expenditure was due to the failure of right hon. gentleman's own policy, and it was no us him to try to put it on to the medical profession. He wi to know why in Glasgow there had not been the re election of the medical panel in connection with he insurance? He understood that medical men in Gla had been pressing for that election and yet the Secretar Scotland had refused to have it. Evidently the right gentleman thought that he would be able to bully successfully in this matter.

Increased Independence.

Sir H. Cautley said he had been much interested in the Secretary for Scotland had said as to the steps that being taken to make the doctors more independent hitherto. The figures as to the increase in sickness disablement benefit during the last three years were serious. From his connexion with the working of approved societies he could say without hesitation tha doctor's position had hitherto been such that in num

s the desire to do his duty had brought him into conflict
n his patient, and that had placed him in a very difficult
tion. He had no charge to make against the doctors as
'hole. The cure for this thing, in his opinion, was to
ease the doctor's independence. He had long thought
there ought to be a period of time elapse before a patient
ld change his panel doctor.

r. WESTWOOD said that a complaint had been lodged in
erent parts of the country, and certainly in his constitu-
y, that medical men were forming themselves into a
ted liability company so that they could dispense the
licines which they themselves had prescribed. In the
inal Act it was laid down that a medical man should
, unless under very exceptional circumstances, dispense
own prescriptions. But the doctors were getting over
difficulty in the way he had mentioned. In the particular
e to which he had referred the prescription instead of being
ded to the patient was taken away by the medical man
self to be dispensed. He hoped that an inquiry would
made into this matter.

Reply to the Debate.

ir JOHN GILMOUR, replying to the debate, asked who
e the people concerned in sickness benefit? One would
gine listening to some hon. members that it was only a
y-hearted Government or the Scottish Board of Health.
people, however, who were as much concerned in this
ter as anyone were the administrators and members of
roved societies. The number of cases on which grave
bt had arisen as to whether excessive payments were
le or not had materially increased. In 1925 the number
ases referred for examination—that was cases upon which
bt was expressed—was 22,231. They rose in 1926 to
16, and they were as high in 1927 as 35,068. In regard
cases examined by the referee, in 1927 the medical
titioner's certificate was upheld in the case of men to
extent of 45 per cent. of those examined, and in the
of women to the extent of 35 per cent. The practi-
er's certificate was reversed in 21 per cent. of the cases
espect to men and 24 per cent. in respect of women. Of
cases which were referred but not examined 15 per cent.
e declared off the fund in respect of men and 19 per cent.
he case of women; and there were not examined for
ous other reasons 5 per cent. in the case of men and
r cent. in the case of women. He had found it necessary
ay quite plainly to the House that there were some
abers of the medical profession who they were convinced
not observing as carefully as they should the duties
h were laid upon them. One must recognise the great
culties under which no doubt many of these cases were
t with, but the fact remained, and it was one which he
red to emphasise. He hoped that the medical profession
ld assist them and the societies concerned and that they
ld not be compelled to take other and more compulsory
hods. In regard to the question raised about the
tion to the medical panel, that was not proceeded with
use there was a doubt as to whether they would be
inued in view of a recommendation of the Royal
mission. If Mr. Westwood would send him any
iculars he had about medical practitioners he would at
have the matter investigated.

ne motion to reduce the vote was rejected by 229 votes
).

HOUSE OF COMMONS.

MONDAY, FEB. 20TH.

Export of Opium from India.

r. CAMPBELL asked the Under Secretary of State for
a what amount of opium was exported from India in
years 1926 and 1927; what was the total amount of
um produced in India in those years and the revenue
ved therefrom; and to what countries the exported
m was consigned.—Earl WINTERTON replied: In 1926
rts were 1,224,140 lb., including 88,000 lb. of medical
m sent to this country; the other destinations being
ch Indo-China, Malaya, Netherlands, East Indies, Siam,
g Kong, Sarawak, State of North Borneo, Ceylon, and
ibar. In the same year the produce of the acreage in
ish India was 1,082,700 lb. The net opium revenue of
Government of India for 1925–26 was Rs. 2,03,52,437.
r figures are not available.

Beds in Military Hospitals.

olonel WOODCOCK asked the Secretary of State for
how many beds there were available in the military
itals in this country; what was the maximum number
pied on any one date of last year; and what was the
ual average number of beds occupied.—Sir L.
THINGTON-EVANS replied: The answer to the first
of the question is 3454, to the second, 3277, and to the
1, 2061.

olonel WOODCOCK asked what was the estimated daily
of each occupied hospital bed and how the cost was approximately made up.—Sir L. WORTHINGTON-EVANS replied: The estimated average cost of an occupied bed a day in the seven large hospitals for which cost accounts are now kept is (*a*) 14*s.* 6*d.* if the cost of unoccupied beds is charged to the occupied beds, and (*b*) 10*s.* 6*d.* if this cost is excluded. The cost is made up approximately as follows:—

	(*a*)	(*b*)
	s. *d.*	*s.* *d.*
Patients: maintenance	3 6	3 6
Staff	7 4	4 8
Standing charges	3 8	2 4
	14 6	10 6

Factory Inspectors in Scotland.

Mr. BUCHANAN asked the Home Secretary the number of factory inspectors appointed in Scotland; if this was the full number allocated for Scotland; if not, when he intended to increase the numbers; and the numbers of inspectors in the same area in 1914.—Sir W. JOYNSON-HICKS replied: The staff now allocated to Scotland comprises 19 inspectors and two inspector's assistants. It is at full strength except for a recent vacancy, caused by the death of an inspector, which will be filled shortly. The staff in 1914 consisted of 16 inspectors and five assistants. The total number, therefore, was the same in both years.

TUESDAY, FEB. 21ST.

Holloway Prison Hospital Staff.

Mr. HAYES asked the Home Secretary the number of staff, superior and subordinate, employed in connexion with the Holloway prison hospital and the daily average of patients in the hospital for October, November, and December last.—Sir W. JOYNSON-HICKS replied: The medical staff at Holloway consists of the governor, who is also the medical officer, and two junior medical officers: the nursing staff consists of one hospital lady superintendent and 26 nurses. The daily average population of the hospital was 111 in October, 96 in November, and 113 in December last.

Opium Cultivation in British India.

Mr. WALTER BAKER asked the Under Secretary of State for India whether official estimates were regularly prepared for the government of India of the total area under opium poppy in British-Indian territory; whether these estimates and later corrected estimates were issued by the Government for public information; whether he would inform the House of the estimated and the actual area devoted to opium poppy cultivation in the year 1926–27; and if any estimate had been published of the probable area so cultivated during the year 1927–28.—Earl WINTERTON replied: The answer to the first part of the question is in the affirmative. The area engaged and that actually cultivated are stated in the report of the Opium Department published after the end of the year. The last report received here is for the year ended October, 1926. The following are the figures in acres for that and the preceding year:—

	Land engaged for.	Land actually measured and cultivated.
1924–25	111,953	114,198
1925–26	72,180	71,057

Army Hospital Accommodation in Portsmouth.

Sir FREDERICK HALL asked the Secretary of State for War what hospital accommodation was provided for Army purposes in the Portsmouth district; what was the number of patients that could be dealt with and what was the average number in residence; and what was the annual cost of upkeep.—Sir L. WORTHINGTON-EVANS replied: There is now no military hospital at Portsmouth. Military personnel are treated either in the Royal Naval Hospital, Haslar, or in the Royal Victoria Hospital, Netley.

WEDNESDAY, FEB. 22ND.

Beds in Service Hospitals.

Colonel WOODCOCK asked the First Lord of the Admiralty how many beds there were available in the naval hospitals in this country and what was the maximum number occupied on any one day of last year.—Lieut.-Colonel HEADLAM, Parliamentary Secretary to the Admiralty, replied: The reply to the first part of the question is 1912 and to the second, 1804.

Colonel WOODCOCK asked the Secretary of State for Air a similar question.—Sir S. HOARE replied: The answer to The first part of the question is 440; to the second, 368 the annual average number of beds occupied was 266.

Poor-law Relief.

Lieut.-Commander KENWORTHY asked the Minister of Health if he had any estimate of the number of persons in receipt of poor-law relief at the present time.—Sir KINGSLEY

WOOD, Parliamentary Secretary to the Ministry of Health, replied: As regards the first part of the question the number of persons in receipt of poor-law relief in England and Wales (excluding lunatics in county and borough asylums, casual, and persons in receipt of domiciliary medical relief only) on Saturday, Feb. 4th, 1928, was 1,208,179.

Tuberculosis in the Navy and Army.

Mr. HORE-BELISHA asked the First Lord of the Admiralty the number of men discharged from the Navy in 1927 suffering from tuberculosis and in how many cases was the disability attributable to service and disablement pension awarded.—Lieut.-Colonel HEADLAM replied: The numbers are 180 and 18 respectively. Pensions were granted on the attributable scale in the 18 cases and on the non-attributable scale in the other cases where the men had sufficient service to qualify.

Mr. HORE-BELISHA asked the Secretary of State for War a similar question.—Sir L. WORTHINGTON-EVANS replied: The number of soldiers discharged from the Army during 1927 on account of pulmonary tuberculosis was 201. 53 cases were regarded as attributable to military service and pensions awarded, and in 88 other cases non-attributable gratuities were granted.

Men Invalided from the Army.

Mr. HORE-BELISHA asked the Secretary of State for War how many men invalided from the Army in 1927 and denied pensions on the ground of non-attributability appealed to the War Office against the original decision; and in how many cases was the decision modified.—Sir L. WORTHINGTON-EVANS replied: The approximate number of men invalided from the Army during 1927 whose disability was considered as non-attributable who appealed or whose cases were referred to the War Office by the Chelsea Commissioners for further consideration was 200. In 77 of these cases the decision was modified. It is not possible to distinguish between appeals made by the men themselves and cases referred to the War Office by the Chelsea Commissioners.

Nystagmus Patients and Unemployment Benefit.

Mr. THOMAS WILLIAMS asked the Minister of Labour whether coal miners suffering from nystagmus were granted unemployment benefit.—Sir ARTHUR STEEL-MAITLAND replied: Coal miners suffering from nystagmus and not in receipt of full compensation under the Workmen's Compensation Acts are in general eligible for unemployment benefit subject to the usual statutory conditions. While I have no statistics on the point I have no reason to suppose that the proportion of disallowances of claims made by such miners is higher than the average. The receipt of partial compensation under the Workmen's Compensation Acts is not a disqualification for benefit, but those in receipt of full compensation would presumably be incapable of work and therefore ineligible for benefit.

Cost of National Health.

Mr. DENNISON asked the Minister of Health the amount expended per annum under the National Health Insurance Acts on sickness and disablement, medical, dental, ophthalmic, hospital, and convalescent homes; and the number of insured persons to whom such benefits were available.—Mr. N. CHAMBERLAIN replied: The amount expended per annum under the National Health Insurance and the number of insured persons vary from year to year. In the year 1926 for Great Britain the amount expended on sickness and disablement benefit and on medical benefit respectively and the mean number of persons to whom those benefits were available were approximately as follow:—

	Amount.	Mean number of persons.
Sickness and disablement	£18,721,000	15,100,000
Medical	9,536,000	15,886,000

The precise amount expended on each of the additional benefits specified in the question cannot be given separately, but the total amount expended on all additional non-cash benefits in the year 1926 was £1,864,000. Inasmuch, however, as the present schemes of additional benefits only commenced in July, 1926, for the great majority of insured persons, the expenditure in 1927 on such benefits was considerably higher and is estimated to have been about twice that for 1926. The annual amounts available, as at July 1st, 1927, in England only for certain benefits, and the numbers of members of societies giving such benefits, were approximately as follow:—

	Annual amount.	Numbers of members of societies giving benefit.
Dental	£2,589,000	12,338,000
Ophthalmic	413,000	11,563,000
Hospitals	292,000	8,656,000
Convalescent homes ..	208,000	9,817,000

THURSDAY, FEB. 23RD.

Ex-Service Men and Medical Treatment.

Mr. COMPTON asked the Minister of Pensions what wa cost per head per week of ex-Service patients under me treatment in institutions belonging to the Ministry a voluntary hospitals during 1925, 1926, and 1927.—M TRYON replied: The table shows the cost per week ex-Service patient in institutions belonging to the Min as compared with the corresponding cost of ex-Se patients in other hospitals for the years 1925, 1926, 1927:—

Year.	Ministry Institutions.	Other hospitals.
	£ s. d.	£ s. d.
1925	3 0 7	2 19 8
1926	3 0 6	2 18 11
1927	3 0 3	2 18 7

Comparison of the cost per head as between the classes of institution is necessarily affected by the fact in institutions controlled by the Ministry the entire m staff is salaried. Moreover, it is to be remembered tha Ministry only maintain separate institutions for treat where that course is necessary to supplement existing accommodation or to provide treatment for special clas disability for which hospital treatment is not othe available.

Mr. HAYES asked the Minister of Pensions the numb established and unestablished whole-time medical o employed by the Ministry during 1923, 1924, 1925, and 1927, and the average number of ex-Service cases treatment during the same period.—Major TRYON re The numbers of established and unestablished whole medical officers (including the whole-time medical sta Ministry institutions) employed by the Ministry durin years in question were as follows:—

Year.	1923.	1924.	1925.	1926.	1
Established ..	3	3	50	50	
Unestablished ..	544	452	329	222	

The average numbers of ex-Service men receiving ment during these years were 71,000, 56,500, 4 34,700, and 27,700 respectively.

Mr. CONNOLLY asked the Minister of Pensions i proposed new hospital was to be in Dunston, Gates and whether it was proposed to administer the hospi association with the Dunston after-care home for dis ex-Service men maintained out of the County of N umberland War Relief Fund.—Major TRYON replied: answer to the first part of the question is in the affirm The premises which are known as Dunston Hill H Dunston-on-Tyne, were formerly occupied by the N umberland Naval and Military War Pensions Volu Fund. The administration of the hospital will be i hands of my Ministry, but I have every reason to hop some, if not all, of the members of the Committee Northumberland Voluntary Fund will serve as memb the Welfare Committee of the new hospital when it is for occupation.

Mr. STEPHEN asked the Minister of Pensions the nu of ex-Service men, suffering from disability of any kin whose care the Ministry was responsible who are treated in institutions belonging to local authorit Scotland and England respectively.—Major TRYON re The number of ex-Service men who are in receipt of trea at the cost of the Ministry in institutions belonging to authorities was, at the end of January, approximately in England and 800 in Scotland.

Small-pox in Aspull and Hindley Areas.

Mr. RHYS DAVIES asked the Minister of Healt number of small-pox cases in the Aspull and H Urban Council areas during the period from Jan. 1st, onwards to date; what were the causes of the outb and what steps were being taken to prevent the d spreading.—Mr. CHAMBERLAIN replied: During the p year five cases of small-pox have occurred in the H Urban District and four in the Aspull Urban District. source of infection of the first case in each district ha been definitely ascertained. The usual steps are being in accordance with a memorandum issued by my depar to prevent the spread of infection, and I am informed b medical officer of Hindley that patients were remov hospital; house and clothing disinfected and co vaccinated or re-vaccinated. Handbills were prepare distributed to every house in the district and large n warning the public of the outbreak and advising vacci were posted in conspicuous positions throughou district. The infant welfare clinic was opened as a vacci centre where the vaccination officer was in attendance

schools were visited and special arrangements made for cination or revaccination. Over 1000 men, women, and dren were treated in this short period. All efforts were red on prevention. Absentees from works and schools e reported to the health department daily and visited. kinema proprietors coöperated and the halls were closed matinée performances. The schools, billiard halls, mployment exchange, and the post office were also nfected and preventive measures taken wherever sidered necessary.

Small-pox and Vaccination.

Mr. GROVES asked the Minister of Health how many of 7956 cases of small-pox classified in the report of the f medical officer of the Ministry of Health for the year 6 as unvaccinated had been vaccinated during the ubation period of small-pox, and the ages of such ients.—Mr. CHAMBERLAIN replied: Of the 7956 cases sified as unvaccinated in the report referred to 459 were sons unvaccinated at the time of infection, but vaccinated ing the incubation period. The following is in reply to last part of the question: The ages of the patients were:—

ler 1 year	15	20 and under 50 years..	64
nd under 6 years ..	80	50 and over	8
,, 11 ,, ..	111		
,, 20 ,, ..	181	Total	459

Poor-law Medical Treatment.

Mr. WHITELEY asked the Minister of Health what was the per head per week of adult persons under medical tment in institutions belonging to boards of guardians in land and Wales during the years 1925, 1926, and 1927 ectively.—Mr. CHAMBERLAIN replied: The average kly cost per inmate in poor-law institutions in England Wales for persons suffering from disease of body or d, for which separate accounts are kept (other than itutions belonging to the managers of the Metropolitan lums District) was 43*s.* in the year ended March 31st, 5, and 42*s.* 6¾*d.* in the year ended March 31st, 1926. corresponding figure for the year ended March 31st, 7, is not yet available, nor are figures distinguishing the of adult persons from that of children.

Hospital Beds for Tall Patients.

Mr. DAY asked the Minister of Health whether his attention been called to the remarks made by the deputy coroner an inquest held on Ernest Seldon Smith at Chelsea in ch it was proved that on account of the deceased's height, ch was 6 ft. 7 in., there was not a bed long enough for in the hospital; and would he give the necessary ructions that at all hospitals under his control there ll be one extra long bed for such tall patients.—Mr. MBERLAIN replied: I understand that the committee he hospital have been asked to consider the question of viding for this kind of emergency. I do not think, wever, that the matter is one in which I could properly e any general instruction.

Tuberculosis in the Air Force.

Mr. HORE-BELISHA asked the Secretary of State for Air number of men discharged from the Royal Air Force in 7 suffering from tuberculosis; and in how many cases the disability attributable to service and disablement sion awarded.—Sir S. HOARE replied: The numbers ed for are 23 and 4 respectively; in addition to the er two cases are still under consideration.

MONDAY, FEB. 27TH.

Inspection of Offices.

Lieut.-Colonel FREMANTLE asked the Minister of Health ny advice was given by his department to local authorities o their powers in the inspection of offices; and whether attention had been called to any difficulties placed in way of local authorities in making inspection.—Mr. MBERLAIN replied: I advise local authorities, on inquiry, t they have powers to undertake systematic inspection of es as well as inspection on complaint. I have not had instance brought to my notice where a local authority been impeded in such inspection. I may add that few ific complaints have been brought to my notice of office ditions.

Small-pox in England and Wales.

Mr. GROVES asked the Minister of Health the number of s of small-pox in England and Wales for each quarter he past year.—Mr. CHAMBERLAIN replied: The following ement gives the notifications of small-pox in England Wales, 1927 (provisional figures):—

13 weeks ended April 2nd		6,153
,, July 2nd		3,753
,, Oct. 1st		1,930
,, Dec. 31st		2,928
		14,764

Treatment of Leprosy in the Empire.

Mr. DAY asked the Secretary of State for the Colonies if any new stations were being built within the Empire for the treatment of leprosy by the hydnocarpus oil remedy and whether he could make a full statement on this subject.—Mr. AMERY replied: In those parts of the Empire where leprosy exists active measures are being taken by medical departments for its control, in many cases in coöperation with the British Empire Leprosy Relief Association and other agencies. Medical officers trained in recent methods have been detailed for special duty in Nigeria, the Gold Coast, Fiji, and other colonies, while in all areas attention is being given to the possibility of the eradication of the disease, by the establishment of treatment stations, as in Tanganyika, Nyasaland, Uganda, or by such other means as the situation appears to demand.

Alcohol and Drug Revenue in India.

Mr. WELLOCK asked the Under Secretary of State for India what was the amount of revenue derived from the sale of alcohol and narcotic drugs in the provincial legislatures of India and what percentage of the total provincial taxation this constituted in each of the last five years.—Earl WINTERTON replied: the following is the information asked for:—

(1) —	(2) Revenue from excise.	(3) Total revenue from provincial taxation, including land revenue.	(4) Percentage of Column (2) to Column (3).
	Rs. Lakhs.	Rs. Lakhs.	
1921–22 ..	1650.3	6177.0	26·72
1922–23 ..	1790.9	6588.0	27·18

TUESDAY, FEB. 28TH.

Coördination of Service Hospitals.

Dr. VERNON DAVIES asked the Secretary of State for War what progress, if any, had been made during the last three years with regard to the coördination of military hospitals at home and abroad with Naval and Air Force Hospitals respectively.—Sir L. WORTHINGTON-EVANS replied: In 1922 the Military Hospital, Chatham, and the Royal Naval Hospital, Gibraltar, were closed. Military patients at Chatham are now treated in the Royal Naval Hospital, Chatham, and naval sick at Gibraltar are treated in the Military Hospital, Gibraltar. Since 1922 the Alexandra Military Hospital at Cosham and the Military Hospital at Devonport have been closed, and military patients in these districts are now treated at naval hospitals. The Joint Medical Services Committee has the question of coöperation between the three medical services continually under review and useful work is being done.

B.B.C. and Medical Practitioners.

Mr. MACQUISTEN asked the Postmaster-General whether the British Broadcasting Corporation was authorised to exercise discrimination between representatives of the medical profession and other practitioners who did not belong to that profession.—Sir W. MITCHELL-THOMSON replied: The British Broadcasting Corporation is entirely responsible for the selection of the persons engaged to broadcast talks or lectures, and I do not propose to interfere with the Corporation's discretion in this matter.

Mr. MACQUISTEN asked if the Postmaster-General was aware that the B.B.C. asked a distinguished osteopath to give a talk. He sent the talk for revision, but they sent it back to have cut out of it all reference to osteopathy. Later, they wrote that, because he was not a doctor—which they had known all along—they would not allow him to give the talk. Would the right hon. gentleman take some authority to prevent such incidents happening again?—Sir W. MITCHELL-THOMSON: I am not officially aware of any of these matters, and I do not propose to interfere with the discretion of the Corporation.

Mr. MACQUISTEN: But I wish you to interfere with their indiscretion.

Small-pox.

Dr. VERNON DAVIES asked the Minister of Health if he would give the small-pox statistics for 1927 in England and Wales, and the number of cases of small-pox for the latest date available.—Sir KINGSLEY WOOD replied: 14,764 cases of small-pox were notified in England and Wales during 1927, and there were 49 deaths in respect of which small-pox was entered on the medical certificate as the cause, or one of the causes, of death. 2582 cases have been notified during the first seven weeks of the present year, but no particulars as to deaths are yet available.

Obituary.

SIR DAWSON WILLIAMS, M.D., F.R.C.P. LOND.,

LATE EDITOR OF THE "BRITISH MEDICAL JOURNAL."

WE deeply regret to announce the death of Sir Dawson Williams which took place at his country house, near Bourne End, on Monday last, Feb. 27th, in the seventy-fourth year of his age. He had for some time been in a precarious state of health, but when at the beginning of the year, he resigned the editorship of the *British Medical Journal*, which he had held for 30 years, it was hoped that freedom from arduous daily work would bring a recovery of strength and enable him to enjoy some years of leisure. His death, however, was sudden and occurred from cardiac failure only a few days after his definite removal from London.

Dawson Williams was born in July, 1854, at Ulleskelf, near York, being the eldest son of the Rev. J. Mack Williams, the rector of Burnby, by his wife Ellen, the daughter of Nicholas Monsarrat. He received his early education at Pocklington School, matriculated at University College, London, went later to the medical school of University College Hospital, and graduated M.B., B.S. Lond. with the gold medal for medicine in 1879. He had already taken the M.A. degree, and two years later he proceeded to the M.D. degree, qualifying for the gold medal in medicine. He took the M.R.C.P. Lond. in 1885 and was elected F.R.C.P. in 1895. At University College Hospital he served as house physician, obstetric assistant, and ophthalmological assistant under such distinguished leaders as William Jenner, Russell Reynolds, Charlton Bastian, Sydney Ringer, Grailly Hewitt, and William Gowers, and Victor Horsley was his immediate contemporary.

Williams's early inclinations towards consulting practice, where he would certainly have won a distinguished place, were marked by a close interest in clinical pathology and especially in the diseases of childhood. After serving as house physician to the Brompton Hospital for Consumption he became registrar and pathologist at the Victoria Hospital for Children, and in 1885 was elected assistant physician to the East London Hospital for Children. During this period he made many contributions to the Transactions of the old Pathological Society, notably one on myosarcoma of the kidney, one on certain aspects of the ætiology of tuberculosis, and one on congenital hydronephrosis, while in 1898 he published his excellent manual "The Medical Diseases of Infancy and Childhood." This volume embodied his experiences at the Shadwell Hospital, and while indicating his own views very distinctly gave adequate space to the teaching of others on points of pathology and treatment, explaining where he was not fully in accord with them. The section dealing with the acute specific fevers and the chapter on diphtheria were recognised at once as excellently concise accounts, and Williams continued successfully his literary work in this direction by contributing to Allbutt and Rolleston's "System of Medicine" the articles upon measles, German measles, infectious coryza, and glandular fever. All these contributions presented the same features of accuracy and the same desire to present fairly opposing views, while their practical nature was indicated by the space devoted to the details of the treatment. There is no doubt that the man who could thus use his opportunities and summarise his own experiences and those of others would have been a successful and probably a great clinician.

But he elected for journalism. As far back as 1881 he became associated with the editorial staff of the *British Medical Journal*, then edited by Mr. Ernest Hart. This connexion, at first desultory, became more and more intimate, until he became assistant editor in everything but name, his colleague being Louis Taylor, a capable journalist and a learned man who never finished his medical curriculum, but who, by a coincidence, started his course by dissecting a li in company with his fellow-student, Willia In 1895 Williams became assistant editor, on the death of Mr. Ernest Hart in 1898 was elected editor. Of that brilliant and singu personality, Ernest Hart, Williams always sp warmly, describing him as one of the most shee clever men he had ever met, and an admira tutor to a junior in journalism; while Hart s learned to depend largely on an assistant owning many qualifications which he did not himself poss During the latter part of Williams's tenure of junior position he was in practical charge of journal, for Hart was a seriously sick man, and du this period the relations between the *British Med Journal* and *The Lancet*, which had been rende difficult by the personal differences between Er Hart and the Wakleys, became cordial—a spirit professional coöperation being introduced wh affected no honourable competition.

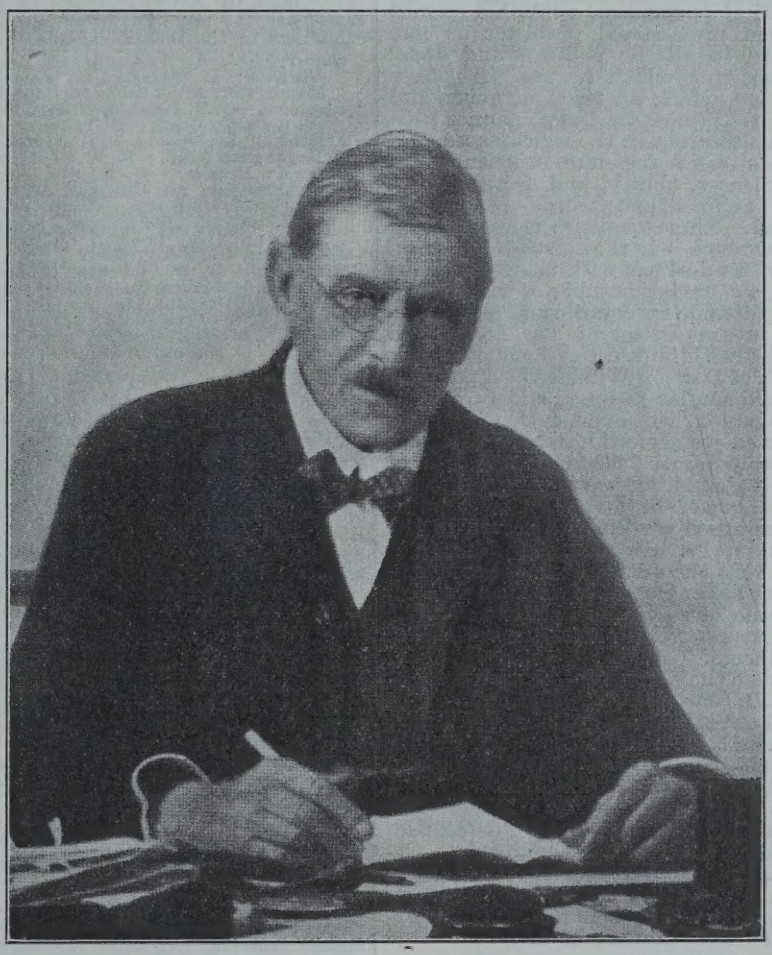
From this time forward Williams's life is reflecte the pages of the journal which he conducted with s conspicuous success and often in circumstances great difficulty. He saw alike the effects of remarkable advances in medical science wh followed hard upon Lister's work and were manifes in every direction of pathological research. He the no less complete changes which occurred in whole conduct of practice through the working of National Insurance Act. And in the meantime constitution of the British Medical Association entirely altered as the result of progressively de cratic modifications; and the membership increa remarkably when the elaborate pattern for transaction of its affairs got into working order. for a prolonged period the task of the editor, ca upon to adjust new principles with old, to advis to future procedure in untried circumstances, an register what was happening from day to day, w contrary views were often held with equal honesty opposing parties in the constituency, was one called for just those qualities of unusual strengt mind and unfaltering fairness of outlook wh Williams possessed.

Dr. C. O. Hawthorne, chairman of the Represe tive Body of the British Medical Association, se the following estimate of Dawson Williams, editor of the *Journal* of the Association and leader or coöperator in its plans for advancem Dr. Hawthorne writes: "Those of us who fo number of years have had close personal and off relations with Sir Dawson Williams have difficult this moment in expressing any thought other than sense of loss which has so suddenly fallen on us. a few weeks ago we said regretfully a formal fare to an editor and a colleague, but we said it with full hope that for him time had many restful hour store and for ourselves opportunities for renewal friendship and of counsel. And now, as it were moment, all these pleasing anticipations close darkness and in some senses in dismay. For behind apparent severity and aloofness Dawson Williams for those who served with him a large capacity comradeship, and qualities which stirred and affection. Not readily known, perhaps, but well w knowing, and genuine and real and sincere. might differ from him in opinion, but no one questio his integrity, and these personal qualities gave him secure position which he held in the esteem and re of his colleagues. With his resignation of the edito chair there was a not unnatural conclusion that work was done, but many of us who have been c to his stores of knowledge and experience and good were counting with confidence on not a few hel associations in the future. The editorship, ind had ceased, but not we knew well the friendship the readiness for service. Now fate has put its on both chapters and left us but memories and regr

"In this brief note of appreciation I must re general impressions rather than particular incide These come from associations, enterprises, responsibilities shared in a common but not an e

rtnership. For with all his knowledge and experi-ce Williams was always ready and indeed anxious, ior to decision and action, to hear the other view. e was, too, a good listener and patient of the other ew, at least to a point, and he would take it from yone so long as arguments could be quoted in its pport. But beyond this moment the caller, parently from some mysterious change in the mosphere, became aware that the editorial time was luable and that the last word had been said. In s own depart-ent he refused be hurried in dgment, but e was not raid of deci-on, and he eached and actised the octrine of itorial respon-ibility in no un-rtain fashion. ot unnaturally took a high ew of the func-on of the *itish Medical urnal* in the heme of the sociation and, deed, in the rk of the pro-ssion gener-ly, and against ything which nded to lessen is claim he as prepared to fer a strenuous sistance. Here, would urge, post-gradua-on training ought to the actitioner's or. Nor were s sympathies any means stricted to the itorial chair. n the contrary, e was alert to l the interests d enterprises the Associa-on and was en to hold ese to the high-st standards. n council he was helpful with information and certain spaciousness of judgment, and though utious he would press the bold view where s convictions were strong. Perhaps he accepted ther grimly an adverse decision, but he had high sense of loyalty to the Association and happily e cultivated a generous measure of humour which nt rather to the ironic side. To be associated with m in the work of a great organisation was to learn ith what abundance of knowledge and experience s mind was equipped, to grow an increasing regard r his high sense of personal and professional recti-de, and gradually to recognise that a great editor as none the less a man and a brother."

Mr. Bishop Harman, treasurer of the British Medical ssociation, draws a moving picture of his dead lleague and friend. He writes: "Dawson Williams as a great gentle man. The last two words are ritten apart, for they then seem the better to describe im than the more common joined word. He was a reat gentle man. A man, great in stature both hysical and mental. A man withal gentle of spirit. His gentleness was manifest behind all the natural mastery which his endowments enabled him to wield. That is my impression of him. It is the impression of a knowledge of some 30 years, reinforced in the last six years by as close a contact as work and social intercourse can give. For those last few years some common ground of work and responsibility in the affairs of the British Medical Association enabled me to learn of him more than all the earlier years of previous acquaintanceship. In the earlier days one knew him as the Editor of the *British Medical Journal*. One whose knowledge seemed almost omniscient in medicine. Withdrawn from the turmoil of research, of discussion, and of practice he seemed aloof, and yet one found him in touch with everyone. No matter how retired some earnest student might seem to others, Williams knew of him and his doings. In those days his word seemed all powerful. There was no recall from his decisions. But latterly we met as it were on a common level, a few around a table. Then his projects might be questioned, his decisions had to be defended. Then one saw how he worked. How carefully he gathered his facts, how he balanced seemingly conflicting observations, and by sheer logic disclosed the inevitable conclusion and the grounds for the action he advocated. For a man possessed of his singular mastery of affairs he was remarkably free from arbitrariness. This thing ought to be done, not because he said it ought to be done, but because he could show the reasonableness of the doing of it. If I were asked to say what I thought was the mainspring of Dawson Williams's work, I should reply without hesitation, love of his profession and—Duty. He loved his profession because it brought relief to sufferers, and he knew as few do what that means. But Duty filled his horizon, and there were no bounds to that; and to him it seemed there could be no praise higher than that duty had been done. When there was under consideration what motto would be appropriate for the 'Gates of Honour' that span the forecourt of the new House of the British Medical Association, and which were erected to the memory of those of our colleagues who had fallen in the Great War, Williams's first choice was 'Duty and Praise.' Though the choice fell upon other words, yet the force of his plea for his preference remains in my mind.



SIR DAWSON WILLIAMS.

Reproduced from a photograph taken in the editorial room of the "British Medical Journal" at the time of his retirement. (By the courtesy of the Editor of the "British Medical Journal.")

It seemed an epitome of his own work. Done often under severe physical handicap and in a life of much sorrow. Yet for him there was duty to be done. He did it. We can speak in his praise."

The words of Dr. Hawthorne and Mr. Bishop Harman need no endorsement; they reveal the man as he was known to those who really knew him. But it is fitting that *The Lancet* should record admiration and affection for the man, as well as our full appreciation of his qualities as an editor. Williams's academic equipment was from the beginning a source of strength in medical journalism, while his trained mind easily grasped professional problems *as they arose*. With regard to all the political and social development of medicine which he saw he had a clearness of judgment which no years of experience ever tempted him to express in facile manner; he was brave or he was cautious in the right places, and his high standards were for him unchangeable. Austerity and gentleness, ability, and fairness were expressed in his actions and words exactly as each was demanded. These qualities were reflected throughout his conduct of the *British Medical Journal* and also in his dealings with members of the medical profession, a countless number of whom must owe him a debt of gratitude for counsel and assistance. Among such is the present Editor of *The Lancet*, and he and all associated with him in the conduct of this paper feel the death of Dawson Williams as a personal loss. We trust that similar feelings, widely evoked in the medical profession, will express themselves in the movement started just before his death to create a tangible memorial to him. This movement will, of course, go on, and it should be known widely that Sir Dawson Williams himself in an interview shortly before his death expressed a wish with regard to the form that it should take. He desired nothing for himself, but hoped that the memorial would associate his name with some advancement of medicine. It is fitting that the name of so wise a champion of our calling should be remembered in connexion with some great and useful scheme.

Many honours were the natural lot of such a man. He was hon. LL.D. Glasg., D.Litt. Durham, D.Sc. Sheffield, and a Fellow of University College, London. He was created C.B.E. in 1919 and two years later received a knighthood. He married in 1882 Catherine, daughter of Robert Kirkpatrick-Howat, D.L. She died ten years ago, but a daughter survives who was her father's greatest care through many years of invalidism and to whom all hearts will go out in sympathy.

The funeral takes place to-day (Friday) at Little Marlow Cemetery, near Bourne End, at 3.30 P.M., while a memorial service will be held on Monday next, March 5th, at St. Pancras Church, at 1.45 P.M.

THE LATE DR. T. C. GUTHRIE.—Dr. Thomas Clement Guthrie, who died on Feb. 18th in his sixty-first year, had been in practice in Tunbridge Wells for 30 years, and was for a long time surgeon to the general hospital there. A grandson of the eminent divine, Thomas Guthrie, he was born at Liberton in Midlothian, and graduated at the University of Edinburgh in 1892. After house appointments at the Royal Infirmary, the Royal Hospital for Sick Children and elsewhere he entered practice at Tunbridge Wells at first in partnership and later by himself. He was a skilful surgeon whose work was much appreciated, and at the time of his death he had just retired from active practice. Dr. Guthrie leaves a widow with one son and one daughter.

THE LATE DR. J. W. KEIGHLEY.—Dr. John William Keighley, of Blackburn, who died on Feb. 15th, after a brief illness, was sixty-one years of age and was a native of Blackburn. He received his medical education at the University of Edinburgh and at the London Hospital, graduating as M.B. Edin. in 1894, and M.D. in 1918. A member of the Blackburn District Medical Society, he served as president for the session 1909–10, and he was also president of the Blackburn branch of the British Medical Association, and hon. secretary of the local medical and panel committee from its inception until three years ago. He took an active part in the public and political life of the town, and was a justice of the peace, an alderman of the borough, and a town councillor from 1907. He also served on the Lancashire Asylums Board for nine years. He leaves a widow, one daughter, and three sons.

Medical News.

UNIVERSITY OF OXFORD.—At a recent congregat the following degrees were conferred:—

D.M.—E. W. Neill Hobhouse, H. A. Gilkes, and D. S. Da
B.M.—R. Oddie.

Dr. A. Massey has been appointed honorary demonstr in public health.

SOCIETY OF APOTHECARIES OF LONDON.—At rec examinations the following candidates satisfied examiners in the undermentioned subjects:—

Surgery.—W. A. A. Collington, Guy's Hosp.; B. Ell Durham; M. Franzler, St. George's Hosp.; G. Fur Manchester, A. E. Gibbs, London Hosp.
Medicine.—G. N. Beeston, Charing Cross Hosp.; M. Fran St. George's Hosp.; H. I. Jones, St. Mary's Hosp.; J Mitchell, Liverpool; N. S. J. Roberts (Sec. 1), Bristol Royal Free Hosp.; R. W. Wood, St. Bartholomew's H
Forensic Medicine.—G. N. Fox, St. Bartholomew's Ho M. Franzler, St. George's Hosp.; K. J. M. Gral Charing Cross Hosp.; W. B. Hallums, St. Mary's Ho H. J. Harcourt, St. Thomas's Hosp.; H. T. Ince, St. M Hosp.; F. M. Lessing, Charing Cross Hosp.; H Rylance, Middlesex Hosp.
Midwifery.—K. D. C. Beckitt, Charing Cross Hosp.; H Bowen, Middlesex Hosp.; M. Franzler, St. George's Ho K. J. M. Graham, Charing Cross Hosp.

The Diploma of the Society has been granted to the follo candidates, entitling them to practise medicine, surgery, midwifery: G. N. Fox, M. Franzler, G. Furniss, and R. W. W

UNIVERSITY OF LONDON.—At a meeting of Senate held on Feb. 22nd the title of Fellow of Unive College, London, was conferred on Dr. Gleb Anrep, lect in physiology in the University of Cambridge, and Sur Vice-Admiral Arthur Gaskell, Medical Director-Gener the Navy. The title of Fellow of King's College, Lon was conferred on Mr. T. Franklin Sibly, D.Sc., prin officer of the University of London, and Prof. Wil Blair Bell, director of the Liverpool (Cancer) Rese Association. Sir Holburt Waring was appointed represent the University at the centenary celebration the Faculty of Medicine and International Congres Tropical Medicine and Hygiene to be held at Cair December next.

University of London: Parliamentary Repres tion.—At the annual general meeting of the Unive of London Conservative and Unionist Association, hel Feb. 23rd, it was decided to adopt Sir John Gilbert a prospective Conservative candidate at the next ge election. He has been an alderman on the London Co Council since 1910. He was chairman of the L.C.C. Ec tion Committee, 1913–17; chairman of the L.C.C. i 1920–21, and chairman of the L.C.C. General Pur Committee, 1921–27. He has been a member of the Se of the University since 1921, and served on the Boa Education Departmental Committee on the Trainin Teachers, 1923.

ROYAL INSTITUTION.—A meeting will be to-day, Friday, March 2nd, at 9 P.M., at 21, Albem street, London, W., when Sir Farquhar Buzzard, R professor of medicine in the University of Oxford, speak on the Psychology of the Sick.

A TOUR IN YUGOSLAVIA.—A medical tour has planned to take place at Easter through Yugoslavia huge and interesting territory which now represents whole of the Balkan area west of Roumania and Bulg with contributions from Austria and Hungary. The will include the ancient capital of Zagreb; Sarajevo little city where the storm burst which involved Euro war; Mostar, the capital of Herzegovina; Cetinje former site of Montenegro rule; the lake of Scutari, Ragusa, perhaps the best known for its beauty of al Dalmatian cities. The journey will also include Spa now known as Split, a town largely contained by a palace of Diocletian; Sebenico, which has a fift century cathedral with unique architectural features; Zara, whose notable churches and Roman remains al attract the visitor of the Adriatic coast. The tour mences on Tuesday, April 3rd, when a departure wi made from Liverpool-street Station for Harwich, at 8.3 Early arrival at the Hook of Holland will allow the trav to dine at Munich on April 4th and in Zagreb on April The next three weeks will be spent in somewhat leis travel, by train and car, and occasionally by boat, thr the centres which have already been mentioned, and schedule suggests arrival back at Harwich early on morning of April 24th, Liverpool-street Station reached by midday. Full information as to expe kit, and details of the tour can be obtained from Mr. Fr Baerlein at the Bath Club, 34, Dover-street, London, W.

ARVEIAN SOCIETY OF LONDON.—A meeting of Society will be held on Thursday, March 15th, at P.M., at the Paddington Town Hall, when the Harveian ure will be delivered by Sir William Willcox, his subject g Toxicology and its Application to Medical Practice.

OURSE IN PSYCHOLOGICAL MEDICINE.— A course ctures and practical instruction for candidates for the oma in psychological medicine will begin at the Maudsley pital, Denmark Hill, London, S.E., from March 6th. iries should be addressed to the director of the Central ological Laboratory at the hospital.

EST KENT MEDICO-CHIRURGICAL SOCIETY.—A ting of this society will be held at the Miller General pital, Greenwich, on Friday, March 9th, at 8.45 P.M., n Dr. Maud M. Chadburn will give an address on the ium Treatment of Cancer of the Cervix Uteri.

ANCHESTER ROYAL INFIRMARY.—The trustees of late Colonel John Barlow, of Bury, have assigned 0 to the new Nurses' Home Fund of Manchester Royal mary.

NIVERSITY OF BIRMINGHAM.—A block of land prising over 40 acres has been presented to the University Mr. and Mrs. Anstruther-Gough-Calthorpe. It lies in immediate vicinity of the present buildings and brings total area owned by the University up to 100 acres.

NIVERSITY OF EDINBURGH.—Dr. W. T. Ritchie, or lecturer in clinical medicine, has been appointed to professorship in medicine in the University vacant by resignation of Prof. Lovell Gulland.

LINICAL STUDY OF RHEUMATISM.—The Central mittee on Rheumatism, International Society of Medical rology, have decided to organise clinical conferences on s of rheumatic disease in hospitals. In connexion with naugural meeting of the Society's French Committee on umatism in Paris on April 2nd a conference will take e at La Pitié Hospital and the Salpêtrière. Further mation may be had from the Secretary of the French mittee, Dr. H. Forestier, 10 rue du Mont Thabor, s (I).

NTERNATIONAL COURSE AT CARLSBAD.—An inter- nal medical post-graduate course, having special ence to balneology, will be held at Carlsbad from . 23rd to 29th. Representatives of the medical faculties Austria, Bulgaria, Czecho-Slovakia, Denmark, France, land, Germany, Italy, Norway, Poland, Sweden, zerland, and the United States of America will give esses, and further information may be had from Dr. ar Ganz, Haus "Pelikan," Alte Wiese, Carlsbad, ho-Slovakia.

ECTURES ON CANCER.—The Yorkshire Council of British Empire Cancer Campaign, in conjunction with Leeds and West Riding Medico-Chirurgical Society, has nged a series of three lectures, open to members of the ical profession without fee, to be given at the Medical ol, Leeds, on Wednesdays, as 3.30 P.M. On March 7th introductory address will be given by Sir Berkeley nihan; on April 4th Prof. G. E. Gask will speak on ium in the Treatment of Malignant Disease; and on 9th Prof. G. Grey Turner will speak on Cancer of the tum. Tea will be provided at 4.30 P.M., and practi- ers who intend to be present are asked to inform the etary of the campaign at 47, Park-square, Leeds, at t two days before each lecture.

IR CHARLES HASTINGS MEMORIAL LECTURE.—The nd of a series of popular health lectures commemorating Charles Hastings will be given under the auspices of the ish Medical Association on Wednesday, March 21st, Sir George Newman, Chief Medical Officer of the Ministry Health and the Board of Education. His subject will be Fundamentals of Health. Lord Cozens-Hardy will take chair at 8 P.M. and admission will be free by tickets inable from the financial secretary of the B.M.A. at Association's House in Tavistock-square, London, W.C. 1, re the lecture will be delivered.

OYAL SOCIETY OF EDINBURGH.—The following lidates, among others, have been recommended by the ncil for election as Fellows of this Society: Dr. A. J. k, professor of materia medica, and Mr. John Fraser, ius professor of clinical surgery, in the University of nburgh; Dr. Kenneth Fraser, deputy medical officer of th for Cumberland; Mr. P. J. Johnston-Saint, secretary he Wellcome Historical Medical Museum, London; R. W. Johnstone, professor of midwifery and diseases omen in the University of Edinburgh; Dr. T. J. Jones, rer in anatomy in the University of Liverpool; Dr. . Mackie, professor of bacteriology in the University dinburgh; Dr. G. H. Percival, assistant physician in skin department of the Edinburgh Royal Infirmary; Mr. Ronald Senior-White, malaria research officer, ral Malaria Research Bureau, Kasauli, India.

DR. SCHWEITZER'S ENGLISH VISIT.—It is stated that Dr. Albert Schweitzer, who has returned to Europe from his hospital at Lambarene in French Equatorial Africa, will arrive in England at the beginning of May for a six week's visit. It is doubtful whether he can arrange lectures in this country, but invitations to give organ recitals will be considered if sent to Mr. J. P. Fletcher at Friends House, Euston-road, London, N.W. 1.

SEAHAM HALL AS SANATORIUM.—On Saturday last Seaham Hall was opened as a sanatorium for the county of Durham. This beautifully situated and historic house has been presented to the County Council by the Marquis of Londonderry, by whose family it was purchased in 1824.

FINANCES OF KING'S COLLEGE HOSPITAL.—Correcting an impression that has got abroad that this hospital is financially prosperous, Prof. W. P. Halliday, Principal of King's College, when presiding over the annual court, stated that there is an outstanding debt of £72,000. There has been, however, on the past year's working a credit balance of £5700; the income just exceeded £100,000.

BETHLEM HOSPITAL.—At a meeting of the Governors held on Feb. 26th the Lord Mayor announced that Sir Charles Wakefield had given £25,000 towards the appeal for £120,000 still required to cover the estimated cost of the new hospital building. Other gifts included £5000 from Lady Cooper. A rural site has been secured for the hospital at the Monks Orchard Estate, Shirley, near Croydon, with a total area of 330 acres.

THE PRACTISING MIDWIFE.—A conference on the place of the practising midwife in relation to the protection of motherhood will be held on Wednesday, March 7th, at 5 P.M., under the auspices of the Midwives' Institute, at the house of the Royal Society of Arts, John-street, Adelphi, W.C. The conference is based upon the report by Dame Janet Campbell to the Ministry of Health, and will be presided over by Sir Francis Champneys. The discussion will be opened by Dr. J. S. Fairbairn.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, March 6th.—8.30 P.M., ORTHOPÆDICS. Discussion on the Treatment of Acute Osteomyelitis. Opener: Mr. Harry Platt. Other Speakers: Mr. Alexander Mitchell, Mr. Eric Lloyd, Mr. Whitchurch Howell, and Mr. W. H. Ogilvie. 8 for 8.30 P.M., PATHOLOGY. Laboratory Meeting at the Lister Institute, Chelsea Gardens, S.W. 1. Papers and Demonstrations: G. H. Eagles and D. McClean: On the Growth of Vaccinia in Tissue Culture. R. W. Fairbrother: Cholera Antigens from the Prophylactic Point of View. J. H. Orr and W. A. Campbell: The Action of *Welchii* Toxin on Red Cells in vitro. M. Robertson: The Behaviour of a Protozoon Exposed to Acriflavine. J. C. G. Ledingham and D. McClean: Propagation of Vaccine Virus in Rabbit Dermis. H. Chick, M. H. Roscoe and M. A. Boas: Pellagra-like Conditions in Rats. (Demonstration.)

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Papers: Dr. Robert Hutchison: A Biographical Note on Sir James Wylie, Bart., M.D., A Medical Adventurer. Mr. F. Prescott: Louis Pasteur and Fermentation. 8.30 P.M., SURGERY. Discussion on Colectomy. Opener: Dr. T. de Martel (Paris).

THURSDAY.—5 P.M., BALNEOLOGY. Discussion on the Value of Marine Health Resorts, with a Special Reference to Children. Opener: Dr. Fortescue Fox. Subsequent Speakers: Dr. Percy Lewis (Folkestone), Dr. W. C. Willoughby (Eastbourne), Dr. Collis Hallowes (Torquay), Dr. G. R. Bruce (Hastings), Dr. W. S. Campbell (Sidmouth), Dr. W. G. Sutcliffe (Margate), Dr. Octavia Wilberforce (Brighton). 8.30 P.M., NEUROLOGY. Discussion on Narcolepsy. Opener: Dr. S. A. Kinnier Wilson.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 5 P.M.) Cases will be shown. 5 P.M., OPHTHALMOLOGY. Clinical Meeting at St. Thomas's Hospital. (Tea at 4.30 P.M.) Cases: P. G. Doyne: 1. Asymmetry of Face. ?Plagiocephaly. 2. ?Parinaud's Conjunctivitis. 3. Atypical Ptosis. Arthur D. Griffith: 1. A Case of Scarring of the Nerve-head (probably birth injury). 2. Hypertrophic Scars in Retina. Fundus Paintings: 1. Scarring of the Nerve-head (see above). 2. Retinal Hole at the Macula. 3. Gumma of Sclera. 4. Gummatous Scleritis. G. W. Kendall: Loss of Upper Half of Visual Field in One Eye. ? Cause. A. S. MacCallan: Tumour of the Iris. H. Neame: ? Familial Macular Degeneration in a Girl. A. Hugh Thompson: 1. Aniridia with Dislocated Lens. 2. Macular "Colobomata." 3. Acquired Central Choroiditis simulating a Second Optic Disc.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.
WEDNESDAY, March 7th.—9 P.M., Dr. F. J. Poynton: Rheumatic Heart Disease in Childhood. (Lettsomian lectures (3).)
THURSDAY.—7.45 P.M., Anniversary Dinner at the Trocadero Restaurant.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY POST-GRADUATE COURSE ON CANCER.
WEDNESDAY, March 7th.—3.30 P.M. (in the Medical School, Leeds), Sir Berkeley Moynihan, P.R.C.S.: Introductory Address.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, March 6th.—5 P.M., Dr. F. A. E. Crew: Individual, Familial, and Racial Inborn Differences in Respect of Immunities and Disease Resistance. (Milroy lecture (2).)
THURSDAY.—5 P.M., Milroy lecture (3).)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, March 5th, to SATURDAY, March 10th.—FELLOWSHIP OF MEDICINE LECTURE, Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Dr. C. M. Wilson: The Chronic Abdomen.—BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck-street, W. Tues., 3 P.M., Dr. F. Hernaman-Johnson: X Rays as an Aid in the Diagnosis of Abdominal Disease (Demonstration of Radiographs).—HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W., Wed., 3 P.M., Clinical Demonstration by Mr. Jefferson Faulder. The above open free to members of the medical profession.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Special Course in Gynæcology—some mornings and some afternoons.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E. Intensive Course in Diseases of Children.—ROYAL EYE HOSPITAL, Southwark, S.E. Demonstrations and Treatment of Diseases of the Eye at 3 P.M., Mon. to Fri. inclusive.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith.
MONDAY, March 5th.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Dr. Trevor Davies: Gynæcological Department. 4.30 P.M., Special Lecture; Mr. Addison: Cancer of the Tongue.
TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose and Ear Department.
WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 3 P.M., Sir Henry Simson: Gynæcological Ward.
FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Ironside: Clinical Demonstration. 4.30 P.M., Mr. Vlasto (Special Lecture): Diagnosis and Treatment of Middle Ear Infections.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.
Daily, 10 A.M., to 5 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments. Anæsthetic and Operative Surgery Classes.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.
WEDNESDAY, March 7th.—4 P.M., Dr. C. G. Lakin: The Medical Dyspepsias.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.
MONDAY, March 5th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Wednesday and Friday, at 2.30 P.M., there will also be demonstrations of Skin and Medical (Children) Cases by Dr. W. Jenkins Oliver and Dr. C. E. Sundell respectively.

NATIONAL HOSPITAL, Queen-square, Bloomsbury.
MONDAY, March 5th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: The Epilepsies.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: The Psychoneuroses (2).
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Methods of Testing the Eighth Nerve (in Out-patient Department).
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Some Forms of Encephalitis.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.
THURSDAY, March 8th.—4 P.M., Mr. H. Tyrrell Gray: Abdominal Pain.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, March 6th.—3.15 P.M. (at the Royal Ch... Hospital), Dr. H. Barty King: Demonstration ... Cases in the Wards.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospi... 49, Leicester-square, W.C.
TUESDAY, March 6th.—5 P.M., Dr. J. E. M. Wigl... Leukæmia Cutis. Mycosis Fungoides.
THURSDAY.—5 P.M., Dr. J. E. M. Wigley: Pemphigus ... Allied Eruptions.

BELGRAVE HOSPITAL FOR CHILDREN, 1, Clapham-ro... S.W.
WEDNESDAY, March 7th.—4.30 P.M., Mr. R. A. Rams... Clinical meeting.

CENTRAL LONDON THROAT, NOSE AND EAR H... PITAL, Gray's Inn-road, W.C.
FRIDAY, March 9th.—4 P.M., Mr. Arthur Brown: Disea... of the Maxillary Antrum.

irths, Marriages, and Deaths.

BIRTHS.

ENBOROUGH.—On Feb. 25th, at Lismore, Camberley, the wife of Dr. Cuthbert Attenborough, of a son.
BBYER.—On Feb. 25th, the wife of Dr. P. W. Boobbyer, of Warwick-road, Ealing, of a son.
WNE.—On Feb. 26th, at St. Katharine's Precinct, Regent's Park, N.W., the wife of Leonard Foster Browne, M.D., of a daughter.
IS.—On Feb. 23rd, at Lower Berkeley-street, W., the wife of K. J. Acton Davis, M.Ch., F.R.C.S., of a daughter.
Y.—On Feb. 23rd, the wife of S. I. Levy, F.R.C.S., of Harley-street, W., and "Ruscombe," Ranulf-road, N.W., of a daughter.
TIN.—On Feb. 11th, at Piercefield Cottage, Park Village East, Regent's Park, N.W., the wife of E. Kenneth Martin, M.S., F.R.C.S., of a daughter.
DRE.—On Feb. 21st, at Birkenhead, the wife of Dr. L. C. Moore, of a son.

MARRIAGES.

LLIAMS—ANGELL.—On Feb. 21st, at Weybridge, Major A. Scott Williams, D.S.O., R.A.M.C. (Ret.), to Dorothy, daughter of the late Lewis Angell, M.Inst.C.E., F.R.I.B.A., of Eastbourne.

DEATHS.

HAM.—On Feb. 14th, at Menton, Hugh Lowrie Askham, M.R.C.S., L.R.C.P., of Pershore, Worcestershire.
KE.—On Feb. 24th, at Hawthorne, Lansdown, Bath, Lieut.-Colonel W. H. Burke, late I.M.S., aged 69.
KROFT.—On Feb. 23rd, at Hazelwood, Lancaster, Mary, the beloved wife of George Cleminson Cockroft.
EN.—On Feb. 16th, at Oxford-terrace, W., Richard John Cowen, L.R.C.P.I.
OCK.—On Feb. 22nd, Alfred George Clarke Pocock, M.B., M.R.C.S., L.R.C.P., L.S.A.
NCE.—On Feb. 19th, at Edderston-road, Peebles, Thomas Fair Hetherington Spence, M.B., C.M.
ERHILL.—On Feb. 20th, suddenly, at Elm Bank-gardens, Barnes, Arthur Stopford Underhill, B.A., M.D., M.Ch., M.R.C.S., D.P.H., aged 78.
LIAMS.—On Feb. 27th, at Bourne End, Sir Dawson Williams, C.B.E., M.D., F.R.C.P., late Editor of the *British Medical Journal*, aged 73.

Notes, Comments, and Abstracts.

CAPTAIN COOK'S DIETETIC SAGACITY.

Dr. R. T. Williamson, in the *Journal of the Royal Naval Medical Service* (January, 1928), draws attention once more to Captain Cook's special contribution to medical science in conducting his long second voyage without any outbreak of scurvy among the crew. He attributed his success entirely to his dietetic precautions, and he enumerates the special articles of food upon which he relied. These were "sweet-wort," given in large quantities as a preventive, "sour krout," a portable soup or broth, and a "rob" of oranges or lemons. He also made a point of taking on board fresh food wherever possible.

Needless to say, when an outbreak of scurvy occurred among Indian troops in Mesopotamia in the Great War, and Lister Institute workers were seeking for portable foods, suitable for victualling an army, their attention was directed to the experience of Captain Cook. They actually made use of the same natural process as he utilised, but in practice, malt, the principal constituent of the sweet wort, was of no use to them. V. Fürst [1] had shown that seeds, upon germination, develop the antiscorbutic principle and his work had been confirmed and extended at the Lister Institute,[2 3] and was made the basis of the principal recommendation. Without a doubt the virtue of Captain Cook's sweet wort must have been due to the anti-scorbutic vitamin, developed in the malt when the barley, of which it was composed, was germinated. But when A. Harden and S. S. Zilva [4] tested modern malt they found that it had no antiscorbutic potency. The explanation lies in the fact that modern malt is kilned, in which process the antiscorbutic vitamin, formed during germination, is again destroyed. Sour krout gave the war workers much thought. When prepared in the modern continental fashion, a process of fermentation is included in the method of preparation, and the cabbage might well retain its anti-scorbutic potency for a long time. For obvious reasons, however, sour krout could not be easily obtained and, as far as is known, is still untested. It would be interesting to know whether it deserves the reliance which Captain Cook placed upon it. Captain Cook's triumph over scurvy was a great victory for empirical knowledge and it is always interesting to look back upon such an achievement and try to interpret it by later exact knowledge. The present instance, however, shows how the inexactness or incompleteness of the record often makes this difficult.

"COMMON HELMINTHS IN MEDICAL PRACTICE." [5]

THIS frankly commercial pamphlet upon santonin contains a summary of present-day knowledge of the life-histories and pathological effects of the roundworm, whipworm, and threadworm, facts and opinions being selected from the literature, over 150 references to which are cited. If conclusions are sometimes drawn over-dogmatically, this in the circumstances could hardly be avoided. Next year will signalise the centenary of the extraction of santonin; that it is still with us is eloquent of its value. Mention is made of the evidence that santonin is not itself anthelmintic, but that in process of its absorption from and re-excretion into the bowel it becomes something which is so, thus falling into line with the action of quinine in malaria, of emetine in amœbic dysentery, and of other active parasiticides in other infections. These considerations suggest, first, that its mode of action is along right biological lines; and secondly, that it is upon such lines that we should look for an anthelmintic efficient against the hookworms. The practice advised conforms with what is known of its mode of action. Apart from idiosyncrasy the dose recommended is grs. 5 for a man, grs. 4 for a woman, grs. 2 to grs. 4 for an adolescent, gr. ½ to grs. 2 for a child, and gr. ¼ to gr. ½ for an infant. Against trichuris and enterobius (oxyuris) a small quantity of added calomel has a virtue by the flow of bile induced. The drug must be allowed ample time—12 hours—to act and presumably to be re-excreted; and must then be removed with the worms by a sharp purge of Epsom salts or castor oil. Helminthiasis of the kinds mentioned is sufficiently prevalent even in temperate countries to prevent the summary dismissal of its consideration.

NEW PREPARATIONS.

WE have received from Messrs. Schering and Co., 3, Lloyd's-avenue, London, E.C., specimens of *Synthalin*, the synthetic preparation whose use is recommended in diabetes. There have appeared in THE LANCET during the last four or five months several authoritative pronouncements on synthalin in the treatment of diabetes, in the light of which the value of the claims made can be estimated. On Sept. 3rd the preliminary reports on this subject to the Medical Research Council were printed in full, and from these it will be seen that synthalin may replace insulin apparently satisfactorily, but only in certain cases. Broadly speaking, the two sides of the insulin action—the depression of new formation of glucose in the liver and the accelerated metabolism of glucose already present in the circulation—are claimed to be represented in the action of synthalin. The question of its practical use has to be decided by the degree to which its beneficial action is complicated by its toxic effects. Without regarding synthalin as an ideal insulin substitute it may be held to suggest hopes of further progress. All the conclusions yet arrived at are drawn from the consideration of a limited number of cases or of investigation extending over a brief period, and will be accepted with caution. Where there is a definite contra-indication of insulin the substitute may fairly be tried, and it is hoped that all medical men using the drug in this more or less empirical way will bear in mind possible toxic effects and keep careful records of their results to serve for future information. The employment of synthalin as a substitute for insulin in Germany appears to be based on evidence derived largely from animal experiments.

We referred in our columns recently (THE LANCET, Jan. 14th and 28th) to a new synthetic remedy entitled *Plasmoquine*, mentioning that, although it was introduced by Prof. Mühlens, of Hamburg, and Prof. Sioli, of Düsseldorf, under the name of plasmochin, and is still issued under that name, it has been registered by the Bayer Products, Ltd. (19, St. Dunstan's Hill, London, E.C.) as plasmoquine. Chemically it is an alkyl-amino-β-methoxy-quinoline salt and is a new synthetic derivative of the quinoline ring. It occurs as a tasteless, light yellow, finely granular powder, freely soluble in alcohol, and only sparingly soluble in water. The action of the acid gastric juice converts it into the freely soluble hydrochloride. Clinically, it has been under trial in cases of plasmodium infection since the autumn of 1925 and satisfactory results are reported in tertian and quartan malaria, and in blackwater fever. In subtertian (æstivo-autumnal) type plasmoquine was found to be more effective combined with quinine than without. The preparation, as now submitted to us by Messrs. Bayer, is made up in tablet form combined with quinine. Each tablet contains 0·005 g. (gr. 1/12) plasmoquine and 0·0625 g. (gr. 1) quinine sulphate. The reason for believing that the addition of quinine renders the plasmoquine distinctly more efficacious in the subtertian variety of malaria, and may therefore render it preferable for prophylactic purposes in undifferentiated cases, may be found in the observations on the effects of plasmochin and "plasmochin compound" on the gametocytes of benign tertian and subtertian malaria, made by Dr. Manson-Bahr in THE LANCET for Jan. 7th, p. 26.

HOSPITALS AND CHARITIES YEAR-BOOK.

AN interesting feature of the latest edition [1] of "Burdett" is a table showing in detail the progress of the Hospital Saturday Fund since 1898, the year in which the street collections were abandoned. Individual funds and their ups and downs can be seen at a glance and the entire movement is thus brought under review. By a convenient rearrangement the institutions controlled by the Metropolitan Asylums Board and the London County Council are now classified with other institutions serving the same purpose, so that all mental hospitals, all sanatoriums, and so on, are now under the same heading. Full particulars of the staff, altitude, climate, soil, and special facilities are now given for each sanatorium, collected from the answers to a questionary sent round to the medical superintendents. New entries give information about the Sunlight League, the Lord Mayor's Fund, Melbourne, the Brisbane and South Coast Hospitals Board, and the Hospitals Board Association of New Zealand. The section relating to provincial teaching hospitals has been expanded so that the personnel of these institutions appears in full. A new subsection is devoted to societies for providing legal aid. The Joint Council of the Order of St. John of Jerusalem in England and the British Red Cross Society has attained an importance which justifies its new place immediately after the King Edward's Hospital Fund.

[1] Burdett's Hospitals and Charities, 1928. Being the Year Book of Philanthropy and the Hospital Annual. Thirty-eighth year. London: Faber and Gwyer. Ltd., 24, Russell-square, W.C. Pp. 618. 21s.

PLAYING AT HEALTH.

IT has rightly been insisted that health must be presen to boys and girls as an attractive thing, worth gaining keeping for its own sake. Too often in the past misgui enthusiasts have sought to frighten children into heal ways by painting a dreary picture of disease, and there still too many books on this subject which have not proper outlook. Dr. J. Maxwell Taylor's recent volu called "The Game of Health" (R. Gibson and Sons, L Glasgow. 1927. Pp. 79. 1s. 6*d*.), is not one of these can be confidently recommended for young children eit as a school reader or as a present for out-of-school ho There is an introductory chapter on games which le straight on to the main idea of the book in Chapter where the "health team" and the "disease team" are out. The various members of these two sides are t dealt with in simple terms and the "playing field" is discussed. The "strategy of the game" is the most import part of the book, and in it guidance on such matters as fo sunlight, sleep, posture, and clothing is presented in clear and sensible way. The central idea is well develop and if there is one small criticism of an otherwise excell little book it is that the author has made no mention of kidneys or sex organs which, with the ingenuity he obvio possesses, he could surely have worked into his sche The modest price should be noted.

A VITAMIN EXHIBIT.

AT the British Industries Fair, which is being held the White City, Shepherd's Bush, till March 2nd, Mes Burroughs, Wellcome and Co. have an interesting exhi of vitamin products, including "Tabloid" Irradia Ergosterol, which finds its chief use as an addition to d known to be deficient in vitamin D. A specimen of V min A Concentrate is also displayed in a tube, the cont of which measure only four-fifths of an ounce. It pres the equivalent of vitamin A contained in 1 gallon of finest quality cod-liver oil. With a view to demonst the space economy of tabloid products the contents "Tabloid" Outfit, measuring only a small fraction cubic foot, is contrasted with the equivalent content their ordinary or uncompressed state, with a capacity nearly 23 cubic feet.

THE "CHARLOTTE" COVER.

THIS cover for the hot-water bottle has features w will recommend it for use with patients or children. this reason it has received recommendation from medical men and from hospitals and nursing homes. It is a well-made bag of plushette, which exactly fits the indiarubber bottle for which it has been designed, while a cap, closely adjusted by studs, protects the stopper. Accidents certainly occur with some frequency through the employment of uncovered bottles, particularly where the patient is very young, or for various reasons unresponsive to pain; this is recognised by the employment of various methods of protection, of which the "Charlotte" cover seems a neat and improved example. The cover is supplied, pink or grey according to taste, by Messrs. C. J. Hewlett and Son, Ltd., Charlotte-street, London, in sizes from 8 in. by 6 in. to 12 in. by 10 in., the price varying accordingly from 19*s*. to 25*s*. per dozen.

A CHEAP RETINOSCOPY LAMP.

Dr. E. C. B. Ibotson (Corris, Merionethshire) wri "There must be many like myself who live in dist where gas and electricity are not available, and who d a cheap retinoscopy lamp. Most of those I have inqu about are not worth the price asked. I have rigged accordingly an acetylene bicycle lamp with a carbon p screen over the glass having a small central aperture. works admirably."

QUEEN'S NURSES.—The name of Queen Victo Jubilee Institute for Nurses has been changed by R Charter to Queen's Institute of District Nursing; all fu Queens are to be the patrons. The institute, which incorporated by Royal Charter in 1889 to provide nur for the sick poor in their own homes, now has 1400 nur associations affiliated to it, and has under its supervi 6300 nurses and midwives, of whom 2700 are Queen's nu Last year these nurses attended three-quarters of a mi cases and paid fifteen million visits.

Hunterian Lecture

ON

ABSCESS OF THE BRAIN:

ITS PATHOLOGY, DIAGNOSIS, AND TREATMENT.

Delivered at the Royal College of Surgeons of England on Feb. 3rd, 1928,

BY E. MILES ATKINSON, M.B., B.S. LOND.,
FELLOW OF THE COLLEGE; ASSISTANT SURGEON, THROAT AND EAR DEPARTMENT, ROYAL UNITED HOSPITAL, BATH.

THE subject of brain abscess is so large that I propose to limit consideration to the common type of case which arises secondarily and adjacent to a focus of infection in the skull—that is to say, mainly to otogenic brain abscesses.

On examination of the literature it is found that any exact description of the general pathology is lacking. Thus Sir William Macewen suggests that an abscess may originate by infection through direct continuity of tissue or by perivascular paths. Preysing reported in 1901 a case which arose from retrograde thrombophlebitis, a report which appears to have been largely responsible for Eagleton's recent elaboration of this mode of infection. But there is no information as to exactly how the infection enters the brain substance or where the abscess starts. Consideration of a few points in the anatomy and physiology of the brain will help in elucidating the problem.

ANATOMY.

The Vessels.—The blood-supply of the brain comes from the circle of Willis by two types of vessel: (1) central branches which pass directly into the base of the brain to supply the central nuclei and the main mass of white matter; (2) cortical branches which pass over the surface, and into the fissures, ultimately dividing into two varieties of terminal branches: (*a*) a large number of short branches which supply the grey matter of the cortex only, and (*b*) a smaller number of longer branches which pass through the cortex to supply a thin layer of subjacent white matter. These are all end-arteries, with no anastomosis between the central and cortical branches, so that there lies just below the cortex and between the terminations of the cortical and central vessels a flat sheet of white matter which is a relatively avascular zone. This zone is present both in the cerebrum and in the cerebellum, but owing to the greater complexity of the cerebellar convolutions its position in the latter is somewhat different. It corresponds to the centre of the white core of each cerebellar folium, which is supplied from either side by the cortical branches, the central vessels supplying the central white matter only. Thus the avascular zone is present in both parts of the brain, but altered in position because of the greater convolution of the cerebellum. It is in this zone, owing to the poor blood-supply, that brain abscesses originate.

The Membranes.—The cortical vessels lying in the subarachnoid space carry down with them into the fissures a sheath of endothelial cells derived on the vessel side from the pia-arachnoid, and on the brain side from the pia mater, the lumen of this sheath being in connexion with the subarachnoid space. These spaces between vessel and brain substance are known as the perivascular, or Virchow Robin, spaces of the brain, and take the place of lymphatics.

Circulation of Cerebro-spinal Fluid.—These perivascular spaces contain cerebro-spinal fluid which arises, according to Mestrezat,[1] as a filtrate through the walls of the choroid plexus and of all the capillaries of the brain, spinal cord, and meninges. It is poured out into these spaces and normally flows outwards along them towards the surface to be absorbed by the arachnoidal villi and the Pacchionian bodies. But Weed[2] has shown that under pathological conditions, where the pressure of the fluid in the subarachnoid space is increased, the direction of flow in the perivascular spaces may be reversed. Infection consequently can be carried down them from the subarachnoid space, and so into the brain substance. In these two facts, the presence of an avascular zone and the reversed flow of cerebro-spinal fluid in the perivascular spaces, we have the basis of the pathology.

PATHOLOGY OF ADJACENT BRAIN ABSCESS.

The osteitis caused by the original infection in the skull gradually spreads until it reaches the dura, causing a pachymeningitis, with or without the presence of an extradural abscess. This area of pachymeningitis induces a subjacent leptomeningitis, so that adhesions are formed between the membranes and the surface of the brain, shutting off the infected area from the main subarachnoid space, just as occurs around a focus of infection in the peritoneal cavity. From this area of localised meningitis infection passes on into the brain substance by one of three routes—perivascular, venous, or arterial.

The Perivascular Route.

This path was originally put forward as a possibility by Macewen, and is, despite statements to the contrary (Eagleton [3]), by far the most common. Evidence of it was found in 13 out of 16 specimens examined (82 per cent.). The process can best be studied in the cerebellum. Sections of the earliest stage show the pial vessels patent, but their surrounding perivascular sheath distended by a gross infiltration of inflammatory cells, mainly mononuclear, and adherent to, and in places incorporated by granulation tissue with, the cortex. This infiltration passes down with the vessels into the fissure against the normal stream of cerebro-spinal fluid, owing to the local increase of pressure. The attack upon the brain is of an extremely localised nature, marked pathological change, as evidenced by œdema and new vessel formation, occurring in one lobule only. Fig. 1 shows a section of a later stage. A small abscess is seen situated accurately in the centre of the white core of one folium, with surrounding inflammatory changes similar to those already described. This is the situation of the abscess which is to be expected from anatomical considerations, in the position of poorest blood-supply, the avascular zone in the centre of the folium. It is impossible, except by chance, to obtain such an early specimen of a cerebral abscess, because, while cerebellar abscesses extend backwards, leaving their point of origin more or less intact, a cerebral abscess extends in all directions around, so that its exact point of origin cannot be demonstrated. But by analogy it seems highly probable that the same thing occurs in the cerebrum as in the cerebellum, the abscess starting in the first place in the avascular zone close beneath the cortex.

The Venous Route.

Infection by this route was found only in two specimens out of 16 (12 per cent.), although according to Eagleton [3] this is the common path. It occurs in the cerebellum usually as a result of the spread backwards of a lateral sinus thrombosis through the pial veins, while in the cerebrum it may be the result of a pial vein being caught up in adhesions and thus infected, so that retrograde thrombophlebitis takes place (Preysing [4]). The histological appearances are characteristic. A section of such a case shows a large pial vein containing breaking-down clot, while the arteries are patent. The vessels in the fissure show the same changes, thrombosis of the vein and patency of the artery. There is a surrounding perivasculitis of mild degree, much less than that which occurs in cases of infection by the perivascular route and due to the infected clot in the vein. Further, the inflammatory cells are of a different type, in this case being polymorphonuclear, as against the mainly mononuclear infiltration of perivascular infections. Infection has entered by a fissure, but the perivascular sheath, though adherent, is not so closely incorporated with the cortex as in the previous group, nor is the

inflammation of the cortex of so marked a degree. Fig. 2 shows the extension of the process. The lobule drained by the veins running into the thrombosed pial vessels is degenerating from interference with its blood-supply—note the veins in the fissures, patent, but distended with blood. This interference is sufficient to cause changes even in the well-nourished cortex, but produces its maximum effect at the point of least vascularity, therefore in the avascular zone. Thus one finds again the development of the abscess in the centre of the white core of the lobule, in precisely the same position as that in which the abscess originated in the previous group. One characteristic feature of thrombotic cases is scattered patches of hæmorrhage which occur in the tissue around the abscess, due to the rupture of small capillaries from over-distension. The abscess once formed extends in a different direction from those of perivascular origin. There the cortex is preserved intact owing to its good blood-supply, and the abscess extends backwards through the centre of the infected lobule. Here, however, the cortex is damaged and extension follows the course of the thrombosis—that is to say, outwards towards the surface, and in doing so destroys the cortex. In these cases the abscess is therefore more likely to track to the surface and burst into the subarachnoid space, causing a generalised meningitis.

The Arterial Route.

This, as regards adjacent brain abscess, is the rarest of the three routes, and occurred in only one specimen out of 16 (6 per cent.). Infection of the artery happens again by its involvement in adhesions, its retention close to the infected bone area and consequent arteritis and thrombosis. If before the lumen of the artery is completely occluded a portion of the clot is swept off, and infarction occurs deeper in the brain, the event is signalised by the abrupt onset of symptoms—apoplectiform, convulsive, or paralytic. Fig. 3 shows the condition in such a case. A thrombosed artery is seen with on either side a vein beginning to thrombose. The cortex around shows very little change apart from hæmorrhage, and this lack of cortical involvement, which is seen also in thrombotic cases before the abscess approaches the surface, is characteristic of a vascular as against a perivascular origin. Similarly, the white matter in the region of the abscess shows little abnormality owing to the sudden onset of the process which prevents the mobilisation of any defensive force. Further away from the abscess cavity a slight venous dilatation is noticeable, but the veins are not engorged with blood nor are there patches of hæmorrhage as in the previous group. This is what would be expected from occlusion of an artery, the tissues being depleted of blood rather than engorged.

THE CAPSULE.

Infection having proceeded to the stage of pus-formation this pus is contained within an abscess cavity, to whose wall the term "capsule" has been applied in the literature. The choice of this word is unfortunate, for it has served only to produce confusion of thought as to the real nature of the limiting membrane. It is in no sense a true capsule as the term is applied to the tissue surrounding a tumour, and is nothing more than the ordinary wall of an abscess cavity, such as occurs in any part of the body, differing in histological structure only in so far as the supporting tissue of the brain differs from that in other parts. The term capsule presumably originated from the fact that at operation, or on section of the brain at post-mortem, the wall of a chronic abscess stands out rather sharply from the surrounding soft tissue of the brain by reason of the presence in it of a certain amount of fibrous tissue. But the fact that a special name has been applied to this wall, suggesting that the pathological process is something peculiar to an abscess in the brain as distinct from an abscess in other parts of the body, has led to a mass of literature accumulating upon the subject of encapsuled and non-encapsuled abscesses, both relation to their pathology and treatment.

There is in reality nothing peculiar about the capsu It represents simply the expression of an atten upon the part of the brain to wall off and limit t

FIG. 1.

Abscess developed accurately in centre of white matter, form centre of lobule. Well away from central mass of white mat Inflammatory changes in both layers of cortex; perivascul in fissures.

spread of infection. In the chronic cases with inf tion of low virulence the wall of the cavity will found to consist mainly of fibrous tissue of greater lesser thickness according to the chronicity of the ca and with a consequent variability in the degree neuroglial hyperplasia. Internal to this is a la of characteristic cerebral granulation tissue—v capillaries contained in a supporting tissue endothelial cells, leucocytes, neuroglial cells, a fibroblasts—while external to the fibrous tissue la is an encephalitis of variable degree and extent, chronic cases mild and limited.

In the subacute cases, the most common type, wh the infection is of moderate severity, the essent three layers are still found, though modified. T inner layer of granulation tissue is thicker and m apparent; the middle layer is less definite, contain comparatively little fibrous tissue, but many neu glial cells, while the surrounding encephalitis is m marked and more extensive.

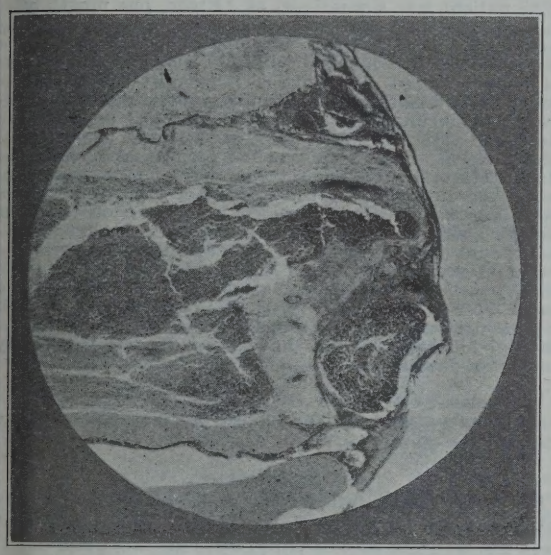
Finally, in the acute abscess, the result eit of a vascular catastrophe or of a fulminating infecti there has been no time for the development of a protective mechanism, and no evidence of a limit pyogenic membrane is found. The contents of t cavity consist of necrotic brain tissue, and a w of acutely inflamed cerebral tissue, which exte more or less widely according to the severity of t infection. This is the non-encapsuled abscess the books and is rather an acute spreading encephali with tissue necrosis than a true abscess.

Direction of Spread.—As the abscess gets larger extends in a definite direction. In the cerebrum increases in size at the expense of the white matt the cortex, by reason of its good blood-supply, be protected until quite late. Extension, though tak place to some extent in all directions, in the m follows the course of the vessels, inwards towards lateral ventricle, into which the abscess may ultimat perforate. The more acute the process the m likely is it to perforate the ventricular wall, whereas chronic cases the choroid plexus tends to beco adherent in the region of threatened perforation a

so prevent its occurrence, acting in the same way as the omentum in the peritoneal cavity. In the untreated case the cortex also will ultimately become involved until only a thin layer of tissue composed of thickened pia and the outermost part of the cortex intervenes between the abscess and the meninges. Eventually, if the patient survives, the cortex may be perforated with the formation of a fistula, so that the abscess discharges spontaneously to the surface, so-called "abscess with stalk."

In the cerebellum extension again occurs at the expense of the white matter, but in this case, of the

FIG. 2.



Abscess in white matter of lobule, extending through cortex to surface along course of thrombosed vessels. Cortex otherwise little affected except for tiny capillary hæmorrhages not well seen in photograph. Veins thrombosed, arteries patent, perivasculitis slight.

white matter forming the core of the lobule, the central mass at first being involved only to a minor degree. The process starts from the anterior end of the cerebellum, picks out one particular lobule, and spreads backwards through that lobule, to which it tends to remain confined. Adjacent lobules are pushed aside and involved only secondarily in the inflammatory process as the size of the abscess increases. It is important to note that the central mass of white matter is not usually destroyed to any great extent; that the abscess itself generally does not approach at all close to the central cerebellar nuclei, in particular the dentate, hence localising signs will be absent unless these nuclei are involved by the surrounding encephalitis; and further, that the shape of the actual abscess is usually ovoid with smooth walls, and not irregular as postulated by some authorities, and stated by Eagleton to be the cause of the difficulty in drainage.

BACTERIOLOGY.

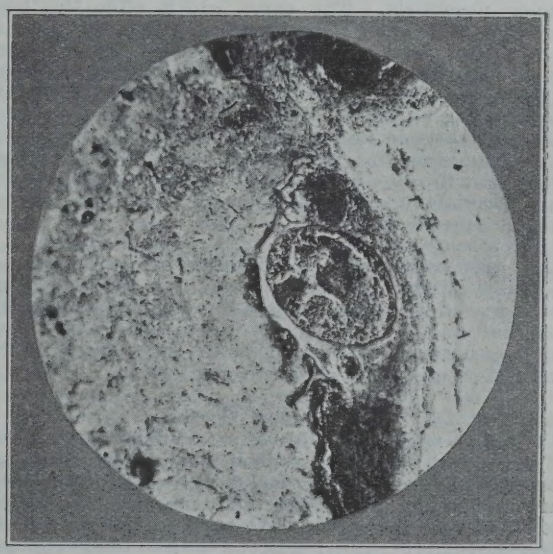
The bacteriology of these cases has been very inadequately worked out, and the results of investigation in the series of cases upon which this lecture is based have not served to throw any further light upon it. Much more work requires to be done before it will be possible to assess the relative pathogenicity of the different organisms found in cerebral abscesses. Lund, of Copenhagen,[5] has produced some evidence which seems to show that in chronic cases the *Bacillus coli communis*, either alone or in conjunction with other organisms, is highly virulent, and that in acute cases the pneumococcus is the organism of which to beware. My own investigations in a very small series (14 cases only) tend to confirm the former observation, though not the latter. It is stated that an anaerobic infection is common, and usually fatal, but sound evidence for this statement is lacking.

REGIONAL PATHOLOGY.

Little needs to be said about the regional pathology of *cerebral abscesses*. Those in the temporal lobe are of otogenic origin, commence in the inferior temporal convolution and spread upwards through the middle, and superior convolutions, and may even become so large as to extend to the neighbouring occipital and parietal lobes, which are otherwise usually involved only by direct infection such as wounds, or by metastatic abscesses. Those in the frontal lobe are secondary to a nasal accessory sinusitis, frontal or ethmoid, and show a high mortality owing to the smallness of the lobe, consequent early perforation of the ventricle, and mechanical difficulties of drainage. In connexion with frontal lobe abscess, it is of interest to mention that cases of brain abscess associated with bronchiectasis, usually considered to be of metastatic origin, are often in the frontal lobe. Adam [6] has suggested, and cited cases in support of his contention, that the real cause in many instances of both pulmonary and cerebral conditions is an unsuspected nasal sinusitis.

Cerebellar abscesses are more complicated as regards route of infection. Like temporal lobe abscesses, they are secondary to infection in the ear, and may be either labyrinthogenic or non-labyrinthogenic. If the former, infection may pass back to the cerebellum commonly by bone necrosis, less often by pre-formed ways, of which there are four: the internal auditory canal, the aqueduct of the cochlea, the ductus endolymphaticus, and the hiatus subarcuatus. Infection by way of the first two more usually results in a

FIG. 3.



Thrombosed artery, two accompanying veins incompletely thrombosed, in wall of abscess. Surrounding acute encephalitis; no evidence of a "capsule."

generalised meningitis; by way of the last is uncommon; which leaves the third, the ductus endolymphaticus, as the usual route in this group. Infection along this route may lead to a cerebellar abscess by formation of a saccus empyema, or by erosion of the bony wall of the aqueduct and the intermediate formation of an extradural abscess. Suppurative labyrinthitis, extradural abscess, and cerebellar abscess are a common triad. If the labyrinth is not involved the route of infection is through the posterior antral wall, either direct through Trautmann's triangle to the dura of the posterior fossa, or more commonly to the lateral sinus and thence to the cerebellum, in either case with or without the

intermediate formation of an extra-dural abscess. Infection having reached the cerebellum enters its substance by way of one of the main fissures, usually either the great horizontal or the fissure below, and this for anatomical reasons. The saccus endolymphaticus lies in relation to the inferior lip of the great horizontal fissure, while the knee of the lateral sinus lies actually on the fissure and turns downwards over the postero-inferior lobule. These being two common routes of infection, it would appear that the postero-inferior lobule is the one most likely to be involved by the cerebellar abscess, and this has in fact been found to be the case in the present series.

DIAGNOSIS.

Discussion of diagnosis will here be limited to the early and less generally recognised signs. The value of early diagnosis as a prelude to successful treatment is as great in this as in other morbid conditions, but the signs generally described are not early, being, on the contrary, rather late manifestations. Continuous severe headache, vomiting of cerebral type, papill-œdema, persistent subnormal temperature and pulse—these, when they are present, are the signs not of an abscess, but of increased intracranial pressure, and therefore, if caused by an abscess, of one either of large size and long standing, or of one surrounded by a considerable area of encephalitis. This increased intracranial pressure has a markedly deleterious effect upon the resistance to infection of the brain substance, and to await its onset before making a diagnosis is materially to diminish the patient's chance of recovery. Again, the well-known localising signs—contralateral paresis and aphasia in temporal lobe abscess; nystagmus, pointing errors and disturbances of muscular tone and coördination characteristic of cerebellar cases—are also evidence of a large abscess or of surrounding encephalitis, both conditions which impair prognosis. The cases which offer the best prospect of recovery are those in which the abscess is of recent development and still small, or is caused by an organism of low virulence so that tissue reaction is good, the abscess wall definite, and the surrounding encephalitis minimal. It is precisely in such cases that diagnosis is most difficult, for until they have attained a large size, these are silent abscesses whose presence will only be suspected by the accumulation and correlation of a number of small and inconspicuous manifestations.

For purposes of description the clinical course of a brain abscess is commonly divided into four stages: the stage of onset, the latent stage, the manifest stage of increased pressure and localising signs, and the terminal stage. With the two latter, the late stages, we have here no concern. It is the importance of the first two stages that I wish to emphasise.

The Stage of Onset.

This is a transient affair of a few days or less, and is characterised by an initial feeling of chilliness, possibly even a rigor, headache, some rise of temperature, and nausea or vomiting. These symptoms are the result of the extension of the inflammatory process from the focus of infection in the skull to the pia mater, causing a circumscribed cortical encephalitis. They are, of course, common to the onset of many diseases, but when they are associated with an adjacent focus of infection such as an acute, or more especially a flaring or grumbling chronic, suppurative otitis media, they should at least suggest the possibility of something more serious than merely an attack of "influenza." In some cases, especially in children and in those of vascular origin, a "fit" is the first sign and may occur suddenly when the patient is apparently well. With an associated suppurative focus this onset of convulsions is stated by Eagleton, and in my experience rightly, always to indicate an intracranial extension, and is the expression of a cortical instability due to irritation from without or to involvement by a process within the brain. An extradural abscess may be sufficient cause. I have seen a case in which an extradural abscess from a frontal sinusitis in a man of 29 was heralded by generalised convulsions and in which cure resulted from simple drainage of the abscess. This is the exception. More often an intracerebral cause must be sought, and the type of fit may give an indication of its situation. A lesion in the temporal lobe results in convulsions of a generalised type, frequently followed by some degree of contralateral paresis. In the frontal lobe they are also generalised, but may start with a conjugate deviation of the head and eyes, while in the parietal lobe they are of Jacksonian type. In cerebellar lesions fits are not characteristic and are a late phenomenon. The following case of the sudden onset of convulsions well illustrates the importance of a due appreciation of this sign.

The patient was a small girl of 2½ who, one month after the onset of a right acute suppurative otitis media following measles, had a generalised convulsion lasting one and a quarter hours, in which twitching of the left side of face and body occurred. When the child recovered consciousness she was drowsy and fretful and had a slight left hemiparesis, which improved during the day and was scarcely detectable after 24 hours. No other signs of an intracranial lesion apart from some drowsiness could be found. The original diagnosis of a right temporo-sphenoidal abscess was overruled by the opinion of a physician and a second aurist, but it was decided to operate on the right mastoid. This was found to be widely infected, but a small area of dura exposed looked healthy and pulsated normally so that no exploration of the brain was undertaken. The patient's condition improved somewhat after this, but a month later she suddenly became unconscious and died. At post mortem a huge chronic abscess was found in the temporal lobe which could have been drained with every prospect of success at the time of the mastoid operation.

This case also brings out forcibly the fact that an apparently normal and pulsating dura is not evidence against the existence of an abscess.

The Latent Stage.

The latent stage follows the stage of onset and may last for days or weeks. It is said commonly that there are no signs at this time, but this most emphatically is not correct. The signs are there, and the aim must be to appreciate them and make a diagnosis in this stage. The patient has passed through a sudden short-lived illness—the stage of onset—from which he has to some extent recovered, but *not completely*, and he has a focus of infection in the skull, such as a running ear. The conjunction of these three events—a focus of infection, a short, acute illness, and an incomplete recovery—should raise strong suspicion of some intracranial extension from that focus. Once suspicion is aroused a search will be made for confirmatory signs, and the following are briefly what may be expected.

Mental changes are very constant, and perhaps the most important of all at this time. A child is apathetic and listless, will not play with his toys and does not resent their being taken away. An adult is drowsy, lacks concentration, and allows his attention to wander; his memory may be faulty and his cerebration slow, so that there is a distinct pause between question and answer, though the answer when it comes is intelligent and correct. A change of disposition is not unusual, the normally good-tempered individual becoming fretful and irritable.

The *general appearance* is often very characteristic. The patient has a greyish unhealthy complexion, looks seedy, the tongue is furred, and the appetite poor.

Headache is always present to some extent, but is not continuous. It is rarely severe, more a dull aching discomfort, and seldom a day passes without it. It is not commonly localised, and if it is the position of the pain bears no constant relation to the position of the abscess. Percussion over the site of the suspected abscess sometimes produces or increases the pain.

The *temperature* and the *pulse-rate* may be of great assistance, and these suspected patients should always be put on a four-hourly chart, or even better, a two-hourly. The temperature is not the accepted subnormal, but shows considerable irregularity about the normal level, as of a septic temperature low down the chart. It may be raised throughout. The pulse

rate in general corresponds with the temperature and is seldom unduly slow, but in most cases it does fall once in a while and become definitely subnormal in relation to the temperature. This is only a transient drop, but is of the greatest significance, and it is to catch this drop that the two-hourly chart is so useful. In a recent case in which the temperature was persistently 99° to 100° or 101° F., and the pulse-rate 90 to 100, a drop on two occasions to between 60 and 70 was a very important factor in deciding to explore.

Lumbar puncture may be of assistance and should be done, as it is a safe procedure in the early days, and only a small quantity of fluid is required. Any increase in pressure or in cell count, with diminished percentage of chlorides, will be valuable confirmatory evidence. For a full account of the changes found in the cerebro-spinal fluid in abscess cases reference should be made to the recent book by Greenfield and Carmichael.[7]

The brief history of one case may help to point the moral of this tale. A boy of 6 was brought to the out-patient department with the story that for two years he had had a running ear, off and on, following scarlet fever. A fortnight before he had a "bilious attack," since when he had complained of headache, and for one day of pain in the ear, which had been discharging again. He had a large marginal perforation in his drum, the tympanum contained granulations, and there was slight tenderness over the mastoid antrum. He looked seedy, was rather sleepy, and took no interest in the proceedings at all. Temperature, 99·4° F.; pulse-rate, 96; resp., 24—nothing very remarkable. There were no signs in the central nervous system. He was admitted with a diagnosis of chronic suppurative otitis media with exacerbation, (?) some intracranial complication, because of his general appearance and the story. At operation, the tympanum and mastoid antrum contained cholesteatoma and offensive pus, and in one place the dura was found bared by erosion, but pulsating and covered with apparently healthy granulations. Nevertheless, it was decided to explore, and while enlarging the bony opening into the middle fossa, a small sequestrum was removed, followed by stinking pus oozing through a small opening in the dura. An abscess containing nearly half an ounce of pus was found and drained, with ultimate recovery of the boy.

Had full credit not been given to the history and mental condition of the child in this case it is improbable that the abscess would have been found at the first operation as there would have been no reason for a further exposure of the dura.

Localisation.—Having diagnosed, or suspected, an abscess in the early stages, it is of advantage to have some idea of its localisation. This is often not possible, and both cranial fossæ may have to be explored, or, at any rate, their dura exposed. But certain indications may put one on the right track. Thus with a focus in the ear a complaint of headache mainly frontal or occipital suggests a cerebellar lesion, as do also suboccipital tenderness or pain or a stiff neck. The association, with general signs of an abscess, of a dead labyrinth or of a thrombosed lateral sinus, would also point to a localisation in the posterior fossa. Per contra, the absence of any of these conditions would lead one to expect the abscess, if present, to be in the middle fossa, where, especially on the right side, abscesses are notoriously silent.

TREATMENT.

If, then, the position be accepted that an abscess must be suspected on much more slender evidence than has so far been considered adequate, the case for the need of earlier exploration of the brain is made. I am far from suggesting that every case of otitis media which has flared and has a headache should immediately have his brain explored; enthusiasm must be tempered with discretion. But I do suggest that it is far better and safer to explore half a dozen brains unnecessarily than to leave one abscess undiscovered for want of exploration. For the latter will die, whereas the other half dozen will come to no harm. Brain exploration with reasonable precautions is a safe and simple procedure, is painless, can be done in bed through an area of exposed dura without an anæsthetic, and is productive of no harmful after-effects. Yet even on the part of otologists, who realise these facts better perhaps than most people, there seems to be a great aversion from taking a chance. The dura is exposed time and again, but too often the evil hour of exploration is put off.

Indications for Exploration.

These are briefly three: (1) Where there are definite localising signs. Our ambition must be to catch cases earlier than this. (2) Where there are general signs of intracranial suppuration associated with a neighbouring focus of infection. The early appreciation of these general signs has formed the gist of the previous section of this paper. (3) Where intracranial symptoms have persisted or recurred after drainage of the primary focus. There are many patients with vague intracranial symptoms which clear up entirely after the focus of infection has been dealt with. In such indefinite cases the correct procedure without doubt is to operate on the mastoid and at the same time inspect the condition of the lateral sinus and the dura of the middle fossa, leaving a widish area of dura exposed and packing the wound open. If the suspicious symptoms do not subside, or if they become more marked, it is a simple matter then to explore the temporal lobe, this being the likely site of the abscess given an intact labyrinth and lateral sinus, and healthy bone between. In suspected cases a dura normal in appearance and pulsation should not be considered as a contra-indication to exploration.

Route of Approach.

Opinion is nowadays fairly unanimous that the best route by which to approach an abscess of the brain is via the originating focus, for which reason the treatment of the condition has passed largely out of the hands of the general surgeon into those of the otologist. There are many advantages in this method. It deals with the source of the infection; the track into the brain can be followed if found and drainage instituted through an area of subarachnoid space already shut off by adhesions; and any additional complication such as an extradural abscess or lateral sinus thrombosis will not be overlooked. The advantages claimed for exploration and drainage through a clean area seem to be theoretical rather than practical, and are not commensurate with the risk of leaving untouched the source of infection and any other possible complications. Therefore a frontal abscess will be approached via the frontal sinus, a temporal abscess via the mastoid with removal of the tegmen, a cerebellar abscess via the mastoid, and an abscess following a wound via the track of the wound. The only one of these which needs enlarging upon is the case of a cerebellar abscess.

Infection enters the anterior end of the cerebellum either by way of the sinus, the labyrinth, or the bone of Trautmann's triangle, and, following the principle of exploring along the path of infection, the abscess should be sought from this aspect. It is undoubtedly the surest way of finding a cerebellar abscess. But drainage presents difficulties on account of the limited space, especially in the event of a forward sinus. If the sinus is thrombosed the problem is simplified; as the sinus has to be obliterated, brain exploration will probably be undertaken through its inner wall, and the dural exposure can be increased to any desired extent by removal of bone on either side. But should the sinus be uninfected the problem of obtaining room becomes more difficult. It is generally recommended that the labyrinth should be opened by Neumann's method, in order to provide this space. This does not appeal as very sound surgery, unless the labyrinth is already dead, for it involves the destruction of a functioning special organ. Further, the extra space provided is not unlimited, and the presence of a drainage-tube in such close proximity to the sinus does not conduce to a feeling of security. I have seen secondary hæmorrhage and infection of the sinus occur from pressure of the tube. Counter-drainage behind the sinus enables a smaller tube to be used in front and a large one behind and is an effective measure for preventing the pooling of pus in

the posterior part of the abscess cavity, which becomes the most dependent part in the recumbent position. But the procedure which seems the most reasonable of any, and which has proved very satisfactory, is deliberate obliteration of the intact sinus. By this means destruction of a functioning labyrinth is avoided, the danger of tube in contact with sinus is overcome, the abscess cavity can be opened up in its entire length if necessary, the operation has no ill-effects upon the patient, and finally it takes much less time than opening up the labyrinth, especially if it is also necessary to do a radical mastoid and remove the promontory to provide drainage.

Some Points of Technique.

(1) *Dural Exposure.*—It is generally agreed that the ideal place through which to explore the brain is along the track of infection, and therefore a thorough exposure of the dura of both fossæ, if necessary, should be made to search for the point of entry. This is not always easy to find at operation, and too much time should not be spent in searching for it. But in the great majority of cases there is a macroscopical point of entry to be found, as is shown by an examination of post-mortem and museum specimens.

(2) *The Use of Antiseptics* should be limited to the dura, upon which they have no harmful effects. It can be sterilised with spirit before incision. The introduction of gauze soaked in iodine into the subdural space to encourage the formation of protective adhesions is unsound. The brain has little resistance to trauma, bacterial or chemical, and the application of antiseptics to it induces an encephalitis and defeats its own ends, a lesson which was learnt in dealing with war wounds of the brain.

(3) *Exploration.*—Having exposed and sterilised the dura and packed off the bone cavity, one is in a position to explore. In the absence of any sign of a track, blind exploration must be undertaken through an incision in the dura. It is better not to explore in more than one direction through the same incision. Three small openings should be made about a quarter of an inch apart with a tenotome, and exploration in different directions made through each incision, otherwise it is possible that pus passing along one exploration track might infect another track which had been unsuccessful in finding the abscess. Further, if several unsuccessful explorations have been made through one incision and later an abscess discharges down one of those tracks, it is impossible to tell which one leads to the abscess.

(4) *Exploring Instruments.*—In general cutting instruments such as tenotomes are to be avoided owing to the risk of dividing a large vessel in the brain substance. I have seen a patient die, and found his ventricles full of blood post mortem, as a result of the injudicious use of a tenotome, the brain, moreover, containing an undiscovered abscess. A cannula is unsatisfactory owing to its tendency to get blocked with thick pus. Some form of angled dilating instrument, such as aural or nasal dressing forceps or a laryngotomy dilator, is very satisfactory, and drainage-tubes can readily be passed along between the blades.

(5) *The Direction of Exploration* should be towards the ventricle in the cerebrum if working from the known point of entry, and backwards in the cerebellum. If working blindly the anterior end of the temporal lobe must be remembered, as abscesses situated here are very liable to be missed. My last case was such a one, only found at the third time of exploration three inches anterior to the roof of the antrum, and I have seen others. In the cerebellum the direction of blind exploration should be always backwards, and upwards or downwards, that is, either side of the great horizontal fissure, if working from the anterior aspect. The instrument should be advanced little by little and opened at each pause if the abscess is not to be missed.

Treatment of the Cavity.

When the abscess is located the exploring instrument is held in position while the original dural incision is enlarged in a crucial manner. The forceps are then opened and a long-bladed Thudicum's speculum is passed along as far as the cavity which can thus be inspected by means of a head-lamp. Finally, two rubber drainage-tubes, one of large bore and the other about half the size, are passed into the cavity between the blades of the speculum to reach just above the floor, and are firmly secured in this position by stitching to one edge of the skin incision. The bone cavity is packed with bipped gauze and the wound left wide open. I believe that nothing more than the insertion of a drainage-tube is advisable as far as concerns the immediate treatment of the cavity. Some authorities, however, advocate a much more complicated toilet. Neumann recommends exploration of the cavity with the finger to feel for small pockets. Whiting has devised an encephaloscope wherewith to inspect the cavity, while others advocate careful mopping out of the whole cavity with pledgets of wool. I am convinced that these procedures are wrong, for the brain is a delicate tissue, easily damaged, much less easily repaired. Moreover the walls of an abscess in the brain are in the majority of cases tenuous and soft, and even gentle palpation could scarcely avoid damaging them, far more so the introduction of an encephaloscope. Insertion of a speculum is, I think, justifiable in order to ensure that the drainage-tube is placed in the cavity and not short of it, or along side it.

With regard to the method of drainage, the two-tube method is very satisfactory. The tubes are of different bores, the smaller one to run fluid through during after-treatment, and the larger to allow it to flow away rapidly and so avoid any pressure in the abscess cavity. Innumerable other methods have been suggested, many no doubt equally satisfactory. The only one in particular that I would protest against is the insertion of any form of gauze, particularly of gauze impregnated with an antiseptic, for it acts not only as an irritant increasing the encephalitis, but rapidly becomes soaked with pus, and serves then as a plug rather than a drain.

After-treatment.

This should be carried out once daily by the same person, if possible by the surgeon in charge of the case or a trained assistant, for much damage may be done by an inexperienced person. The patient sits up in such a position that the tubes are dependent, and it is often surprising how much pus drains away simply by this alteration of position. The cavity is very gently washed out with saline or Ringer's solution through the small tube until the washings come away clear. This is a purely mechanical process, and the introduction of any antiseptic whatever is to be condemned. The cavity is carefully emptied by posture and the dressings are replaced. If the discharge is very copious the outer dressing may be changed as often as necessary, but the abscess itself should be left alone. The two tubes are best left undisturbed for about a week until a track has formed, and when ultimately they are removed for cleaning they should be taken out one at a time, replacing one before removing the other, and making quite certain that the tube is actually in the abscess cavity. If only one tube is used, or if both are removed at the same time, it is very easy in replacing the tube to make a fresh track and place it alongside, and not into the abscess. Drainage should be maintained until the abscess cavity is completely obliterated.

If these various points are carried out with meticulous attention to detail complications such as pocketing, second abscess formation, and hernia, which are due in the main to defective drainage, will be little likely to occur.

OBSERVATIONS ON THE MECHANISM AND ELEMENTS OF PLEURAL PAIN.

By A. I. G. McLAUGHLIN, M.B., Ch.M. Syd.,
TUBERCULOSIS DEPARTMENT, ST. THOMAS'S HOSPITAL.

It is generally accepted that the pain associated with inflammation of the costal pleural membrane is sharp and lancinating, that it is more intense on coughing and at the end of a deep inspiration, and that it abates on expiration; that it is experienced in the lower part of the chest, usually in the region of the anterior axillary line; and that pleurisy towards the apex of the lung causes a dull ache and not a sharp inspiratory pain. Further, it is accepted that the visceral pleura is insensitive, that the costal parietal pleura is richly supplied with sensory nerves (from the intercostals), and that certain types of irritation or stimulus to the membrane are experienced by the patient as definitely localised pain. Considerable differences of opinion exist, however, on the mechanism of production of pleural pain. The most generally accepted view is that it is produced by the inflamed pleural membranes rubbing and pressing against one another. This may be termed the *friction theory*. Mackenzie [1] was the first to question the friction theory, and he advanced the *muscular theory*, namely, that the pain is due to hyperalgesia of the intercostal muscles. He based this theory mainly on the assumption that the parietal pleura, like the visceral, is insensitive. Recently Bray [2] has enunciated what he calls the *tension theory* of pleural pain, viz., that the pain is caused mainly by tension or stretching of an inflamed parietal pleura.

The following cases are interesting as examples of varying types of pleurisy studied with the object of determining the mechanism and elements of pleural pain; in the main they tend to support Bray's tension theory. For the purposes of this paper cases of diaphragmatic pleurisy have been excluded, as the mechanism of the primary and referred pains in this condition differs from that of costal pleurisy. The sensory nerve-supply of the diaphragmatic pleura is also more complex (see Capps [3]).

Acute Pleurisy Supervening during Artificial Pneumothorax.

I have observed in many instances that when pleurisy comes on during the course of an artificial pneumothorax, the pain is similar in all respects to that of acute pleurisy when the lung is not collapsed—i.e., it is more severe during inspiration and diminishes during expiration, and is felt almost invariably towards the base of the chest. In addition, during the acute stage, an area of hyperalgesia of the skin is constantly present. The following case is a typical example.

A girl, aged 19 years, had pulmonary tuberculosis involving the left lung. Artificial pneumothorax was induced on Nov. 20th, 1926, and complete collapse was obtained about five weeks later. On May 13th, 1927, three days after a refill had been given, she complained of severe pain in the lower part of the left side of the chest. She described the pain as "like a knife going through the chest from front to back." On further questioning she said that the pain was worse on coughing and during inspiration. She also complained that the skin over the region of the pain was tender to the touch.

On examination the signs of complete pneumothorax were found. A succussion splash was not heard. As would be expected, no friction rub could be detected. An area of hyperalgesia of the skin was found over the lower part of the front of the chest and axilla, about 8 in. in diameter, involving the areas of skin supplied by the sixth to the ninth intercostal nerves. The distribution of the hyperalgesia was not segmental. An X ray examination of the chest showed that the left lung was completely collapsed. The hyperalgesia persisted for 12 days, and a succussion splash was heard on the fourth day after the onset of the pain, showing that a small pleural effusion had formed. The characteristic pleural pain lasted for about eight days. On one occasion during the period of acute pain, an attempt was made to determine the intrapleural pressure, and it was found, on introducing the needle of a hypodermic syringe into the parietal pleura, that the membrane was exquisitely tender, and that novocaine failed to produce local anæsthesia.

This was a case of acute pleurisy coming on while the lung was collapsed. The pain was characteristic of pleural pain—i.e., it was worse on coughing and at the end of inspiration, and abated during expiration. The lung was definitely collapsed, and there was no possibility that the pain was caused by friction between the two layers of the pleura. An additional element was the broad area of hyperalgesia, which persisted for twelve days. The parietal pleura was extremely sensitive, and the patient was able to localise accurately the pain caused by the introduction of a needle into the pneumothorax cavity.

Pneumonia Complicating Pulmonary Tuberculosis.

A man, aged 49, admitted on Feb. 18th, 1927, under Dr. G. T. Hebert, who kindly allowed me to study and report the case. He had suffered from chronic bronchitis for 26 years, and was subject to attacks of asthma. For several months his general health had been failing, and tubercle bacilli had been found in his sputum. For ten days after admission his temperature chart showed a typical evening rise to 99° F., but on March 1st he developed a sharp pain in the lower part of the right chest; the temperature rose to 101° F., and the respiration-rate to 40 per minute. He described the pain as "a knife going through the chest," and as more intense on inspiration. The cough was suppressed, as it caused great pain, and he complained that the pressure of the bed-clothes hurt his side. There was an area of cutaneous hyperalgesia 4½ in. in diameter on the postero-lateral aspect of the right side of the chest, extending from the eighth to the twelfth rib (not segmental in distribution). On auscultation, a loud friction rub was heard exactly over the area of hyperalgesia. The inspiratory pain was experienced by the patient in the same place. Elsewhere over the right lower lobe the breath sounds were distant, and medium crepitations were heard. The acute fever and rapid respirations persisted for ten days, after which the case resumed its usual character. The hyperalgesia persisted for four days, the inspiratory pain for six days, but the friction rub could be heard as late as the tenth day.

The important points were: (1) that the friction rub could be heard even after the pain had ceased, showing clearly that friction per se is not the cause of pleural pain; (2) that the friction rub and the area of hyperalgesia were exactly superimposed; and (3) that the hyperalgesia was a single broad area of non-segmental distribution.

Acute Pleurisy Associated with Fibrosis of the Lung and with Pleural Adhesions.

A woman, aged 46, whose illness started in 1911 with hæmoptysis. For three years she was quite well, until in March, 1914, she developed a pleurisy with effusion on the right side. From then until the present time she has been under regular supervision. She has had frequent attacks of pain, pleural in type, on the right side, with dyspnœa and occasional hæmoptysis. In May, 1926, she was found to have definite fibrosis of the right lung. X ray examination showed that the heart was displaced about two inches towards the right side, and calcified opacities were seen in the right lung. It seems reasonable to assume that dense pleural adhesions were present at the right base. On Dec. 4th, 1926, she had an attack of pain in the right side, associated with a slight hæmoptysis. She described the pain as "going through the chest like a knife," and as worse on coughing and on "breathing in." She also complained that the skin was tender. On examination it was found (1) that the heart was displaced to the right; (2) that an area of cutaneous hyperalgesia about five inches in diameter was present on the lateral wall of the chest, extending above to the fourth rib, in the mid-clavicular line; (3) that the breath sounds were distant over the right lower lobe, but that crepitations, superficial in character, could be heard over the base of the chest, especially over the site of the pain.

The side was strapped and the patient sent home to bed. When she was seen after a week, the pain and hyperalgesia had disappeared.

The essential points in this case appear to be: (1) The pain was of a typical pleural character, and was due probably to tension or stretching of the inflamed parietal pleura. (2) Owing to the dense pleural adhesions preventing friction between the pleural membranes, superficial crepitations and not a friction sound were heard. (3) The cutaneous hyperalgesia

was, as in Case 2, situated over the apparent area of pleural inflammation. It seems to be a reasonable deduction that, as the skin of the chest wall and the costal parietal pleura are supplied by the intercostal nerves, the areas of skin and pleura supplied by the same nerves are more or less superimposed.

Acute and Chronic Pleurisy in Unresolved Pneumonia.

Cases of mild, ambulant, unresolved pneumonia are comparatively common. The following case is a typical example and presents several instructive features concerning the nature of the pleural pain.

A woman, aged 32, attended the out-patient department on May 10th, 1927, and gave a history of having had cough and sputum, sweating, dyspnœa, and pains in the chest for 14 days. She had not stayed in bed because her husband had not allowed her to. She described the pain as being like a knife going through the left side of the chest, and as being worse on coughing and breathing. The temperature was 100·4° F., and the respiration-rate 28. Her skin was slightly cyanosed, the percussion note was impaired at the left base, the breath sounds were distant, and a few faint crepitations were heard over the same area. No friction rub, hyperalgesia of the skin, or deep tenderness was present. The heart was not displaced. Tubercle bacilli were not found in the sputum. The X ray report was "opacity at the left base; suggests resolving pneumonia."

She was kept under observation at intervals until August 30th, 1927, during which time the pains in the left side persisted, but gradually became less severe. It was noticed that she developed a slight tenderness on deep pressure over the skin of the lower part of the left side of the chest. Further X ray examination showed that the opacity at the left base had cleared considerably, but that some shadowing was still present. In December, 1927, it was noticed that the heart was displaced a little to the left. She still complained of pains in the left side, but they were more dragging in nature.

It appears that this is a case of very early fibrosis of the lung following an unresolved pneumonia, the pains being due to adhesions dragging on the parietal pleura. In this instance the usual initial hyperalgesia of the skin was not observed, as she was not seen until 14 days after the onset of the illness.

Discussion.

The four cases briefly described illustrate several factors in the production of pleural pain. In the first case the friction theory does not explain the pain, because the pleural surfaces could not possibly rub against each other; in the second, the existence of a friction rub without pain suggests that friction is not the primary factor; in the third, the characteristic pleural pain was present, although friction was prevented by pleural adhesions. In all three cases the additional factor of cutaneous hyperalgesia was present. The fourth case shows, in the first place, the presence of pleural pain without a friction rub, and, secondly, the dragging pain and deep tenderness associated with comparatively recent pleural adhesions.

I have not attempted to state all the points for and against the three theories of pleural pain, as too much space would be required. Bray gives a very good discussion in his original paper,[2] supporting the tension theory. If the friction theory is correct, the pain of pleurisy should be felt equally throughout inspiration and expiration, and not only at the end of inspiration. Strapping the chest with adhesive plaster gives almost complete relief from the sharp lancinating pain, not because friction is diminished or abolished by immobilising the ribs, but because stretching of the costal parietal pleura (which is attached to the inner surfaces of the ribs) is prevented. Mackenzie's muscular theory is based on the erroneous idea that the parietal pleura is insensitive. Again, it is not made quite clear whether the muscular hyperalgesia affects either or both the internal or external intercostal muscles. If both are involved pleural pain would be experienced equally on insp ration and expirat on. It seems quite possible that hyperalgesia of the intercostal muscles or of the deep fascia exists as a secondary element of the pain of the acute stage of pleural inflammation, but, if so, it is masked by the cutaneous hyperalgesia. The observation that the pain of acute pleurisy subsid when a pleural effusion forms is frequently cited i support of the friction theory, because frictio between the two layers of the pleura is thus pr vented. At least two alternative explanations ca be given: (1) That the pain is present during th acute congestive stage of inflammation of the pleur and dimin shes during the stage of œdema or effusio owing to the fact that, by the exudation of the fluid the end organs of the sensory nerves in the pleur are released from considerable pressure. (2) Tha the effusion causes collapse of the lung and diminish the amount of movement of the affected side of th chest, and also the amount of inspiratory stretchin of the parietal pleura.

The following provisional conclusions may be state as a working hypothesis on which to base furth investigation into the nature of pleural pain.

1. The ma n element of pleural pain—i.e., th sharp lancinating pain worse on deep inspiration- is due to tension or stretching of the inflamed pariet pleural membrane.

2. The tension may act in the plane of the men brane, as in the stretching on deep inspiration i acute pleurisy; or it may act tangentially, as i the dragging pains experienced when pleural adhesion are present.

3. The subsidiary elements of pleural pain are (1) in acute pleurisy, hyperalgesia of the skin ar possibly of the intercostal muscles or deep fasc overlying the inflamed parietal pleura; (2) in chron pleurisy, slight tenderness of the deeper structur (also overlying the affected pleura), either of th intercostal muscles or the deep fascia. In an acu exacerbation of chronic pleurisy cutaneous hype algesia is frequently found.

4. The hyperalgesia of the skin situated over a inflamed parietal pleura is a phenomenon which las usually for five or six days and sometimes longe In the majority of cases it may be taken as an ind cation of an acute inflammatory process of th parietal pleura. Further, in association with cost pleurisy the hyperalgesia is invariably local or dire and not segmentally referred (cf. Head [4]).

CHRONIC OSTEOMYELITIS IN LONG BONES.

By H. HALLILAY, M.B. Lond.,
LIEUT.-COLONEL, I.M.S.; CIVIL SURGEON, RAWALPINDI.

Chronic bone disease, if syphilis, tubercle, ne growth, and mycetoma be excluded, common presents itself to surgeons in India in one of tw forms.

1. Massive necrosis of the whole or part of th original shaft, which is enveloped in new bone, wi suppuration and sinus formation. This form is d to an attack of acute osteomyelitis, of which it is th sequel; it may cause intense suffering and discomfo to the patient and is liable to end in death fro amyloid disease and exhaustion.

2. A chronic overgrowth and sclerosis of the sha of the bone with or without the formation of sinus In this form there may be no outward sign of th sepsis which is lying in the heart of the bone, n sinuses, and none of the recurring abscesses which a so common in the first form. Sequestra may b formed and vary in size from tiny spicules to conside able fragments.

The outstanding clinical feature of both the varieties is chronicity; they may persist for year from early childhood to adolescence, and fro adolescence far into adult life, until an unusual severe exacerbation of sepsis or the onset of amylo disease ends the patient's troubles. From the actuari

)int of view these cases are "bad lives." The history a depressing one, and usually a record of continuous intermittent suppuration from a persistent sinus or nuses, alternating with recurrent acute trouble, llowed by operation and inevitable disappointment. fter these interludes of pain, insomnia, and fever ıe flow of pus resumes.

The surgical problem is the obliteration of a septic vity with rigid walls. Some have adopted the ethods of a dentist when dealing with a carious tooth, filling the cavity with an amalgam of metals, or the use of decalcified sponge. Others have poured)t antiseptic pastes into the cavity; these set solid ı cooling. Others, again, endeavour to effect the)literation of the cavity by means of pedunculated afts of muscle; this procedure is obviously doomed failure if there is any residual sepsis in the cavity.

The success attending these methods has been, on .e whole, mediocre, but they have all one aim in mmon—viz., the obliteration of the bony cavity. ıe method to be described has the same object, but tains it, not by the introduction of a foreign body to a cavity, but by converting the cylinder of bone to a lath, nothing but the posterior thickness of the aft being left. The free removal of all overhanging ıgments permits the periosteal sleeve to collapse)on the residual strut of bone. New bone is rapidly id down from the contiguous surfaces of bone and riosteum.

Technique.

The conservation of the periosteum is essential in this eration. The incision is made down to the bone on the rgical aspect through the periosteum, for the whole length the diseased area. The periosteum is then carefully parated from the bone with a rougine, which should have chisel edge of razor-like sharpness, so that an abundant pply of bone-cells from the cambium layer is elevated with e periosteum. The subsequent rate of repair will be rectly proportional to the care with which this operation carried out. The periosteum is separated up to the limits the bone which it is decided to retain; it is essential to ntinue the removal of bone until nothing is left but the o plane surfaces of the posterior aspect of the shaft. ith ordinary care, working within the periosteal sleeve, e danger of damage to soft parts is negligible. With an equate incision an ample exposure is secured and nothing ed be done in the dark. Free exposure and a good light e indispensable, for if a focus of sepsis is overlooked the ccess of the operation may be jeopardised.

As soon as sufficient bone has been stripped of its peri- teum the cavity of the shaft is opened by suitably planned ts into the bone. This may be done by an Albee's saw or th chisel and mallet. The electrically-driven saw saves uch time and labour, but the necessary trimming of the aft may be effected with chisel and gouge. The surface bone which remains is carefully scrutinised for areas of crosis, sinuses, or actual perforations, and all diseased sue is energetically removed.

The surgeon then ascertains how far the periosteum and tached soft parts will glide in over the remains of the aft and removes any projections interfering with this, as is important to reduce the number of dead spaces to a nimum.

When the operative area is near a joint great care ust be exercised to avoid damage to the articular rtilage, and the removal of bone should be so anned as to avoid too steep a descent. This is rticularly necessary when dealing with the tibia, too steep a gradient renders it difficult to get the w surface of the bone covered by the flaps of soft ssues and periosteum.

When all the diseased tissue has been removed ere remains a keel of bone to which is hinged on ch side a flap of periosteum which originally covered lf the expanded shaft and which still preserves its iginal connexions with the soft parts and therefore blood-supply. These flaps are united in the line the original incision by interrupted silkworm-gut tures. This abolishes nearly all the dead space, y gap at the upper extremity of the incision being ugged with gauze and allowed to fill up from the ttom. If all the diseased tissue has been removed vities will become obliterated by a vigorous growth close healthy granulations, and there will be no ore discharge than is usual with any granulating surface. Increase of or persistence of discharge means some undetected focus of caries, or recrudescence of caries in some part of the bone, and demands a further minor operation.

Illustrative Cases.

CASE 1.—Aged 28; duration of disease, one year. Admitted May 2nd, 1923. History of much pain and disability in the leg.

Operation (June 10th, 1923).—Great thickening and sclerosis of bone, and caries in medullary canal extending nearly half the length of the shaft. Complete operation, removal of all but a lath of bone so as to leave no over-hanging edges. The separated leaves of periosteum came into good contact with the denuded bone. Convalescence was uneventful, and there was abundant formation of new bone. The wound healed by first intention. Discharged July 28th, 1923. Days in hospital after operation, 49 (seven weeks).

CASE 2.—Aged 22. Necrosis. Chronic osteomyelitis of the right tibia. Leg riddled with sinuses. Duration, ten years. Admission, July 3rd, 1923.

Operation (July 9th, 1923).—Complete operation. Bone greatly sclerosed and thickened. Rarefying osteitis, pus, no massive necrosis, no involucrum. All bone removed in anterior and lateral aspects, only a lath of bone left. The periosteum was carefully conserved. One small secondary operation was found to be necessary. The lower half of the wound healed by first intention, but there was a small cavity left at the upper end which was not quite healed when the patient left the hospital in October. Stay in hospital after operation, 86 days.

CASE 3.—Aged 12. Much discharge, massive necrosis and involucrum. Admitted July 30th, 1923.

Operation (July 31st, 1923).—Complete removal of all but posterior layer of involucrum, cylinder of necrosed shaft removed, as it was lying free in the cavity of the involucrum. Periosteum came into good contact with the denuded area. The lower half of the wound healed by first intention, but a cavity was left in the upper half, which was plugged daily with plain gauze and granulated up. Discharged Sept. 24th, 1923. Stay in hospital, 56 days.

CASE 4.—Aged 12. Chronic osteomyelitis of left tibia. Duration, six months. Admission, June 4th, 1923. Foul and copious discharge. General health very poor.

Operation (June 12th, 1923).—Removal of sequestra and of all but posterior part of the bone. Periosteum in good contact with denuded area in lower two-thirds of the wound. Cavity left in upper third, which was plugged. Discharge persisted, so wound was explored August 21st, 1923, and a large piece of old necrotic bone found under an overhanging ledge. This was chiselled away, and the piece and all granulations removed. Gauze packing, wound securely healed in its entire extent by Nov. 10th, 1923. General condition much improved. Stay in hospital, 152 days.

CASE 5.—Aged 15. Chronic osteomyelitis of the left ulna. Duration, one year. Ulnar border of the arm was riddled with sinuses.

Operation (July 10th, 1923).—Large sequestrum round rather patchy involucrum, many sinuses, periosteum came into good contact with the denuded surface of the bone. Discharged August 29th, 1923. Good formation of bone and wound solidly healed. Stay in hospital, 50 days.

If the solidity of the residual shaft of bone permits the patient should be allowed upon his feet as soon as the wound is soundly healed, or earlier if there is any delay in healing. Use is the best stimulus to bone growth. To secure rapid healing and the best results the surgery must be very bold and radical; half-hearted operations are better left undone.

ROYAL MEDICAL BENEVOLENT FUND.—The following are some additional cases relieved at the last meeting:—

M.B. Edin., aged 40, married, three children, two daughters aged 17 and 4, and son, aged 12. Applicant's appointment abroad ceased in September, 1927, and he and his family arrived in this country in November, and have since been living on what small resources they had which have now come to an end. Has been unable to secure any appointment. £7 16s. was given them by the Social Service and the Church, £6 by the Guild and the Fund voted £10 for immediate necessities.

Daughter, aged 45, of L.R.C.P. who died in 1886. Both she and her sister have supported themselves by teaching in schools, and the applicant is now bedridden from rheumatoid arthritis and is entirely dependent on her sister. Friends have done their best to help with expenses for special treatment, but this has been of no avail. Asked Fund for grant to enable applicant not to be an entire burden upon her sister. Voted £26.

Subscriptions may be sent to the hon. treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

FRACTIONAL TEST-MEAL ANALYSIS.

A SIMPLIFIED TECHNIQUE, WITH SPECIAL REFERENCE TO CHLORIDE ESTIMATIONS.

BY JOCELYN PATTERSON, M.Sc. DURH., PH.D. ST. AND.,
BIOCHEMIST, CHARING CROSS HOSPITAL.

IN theory the study of gastric function by the fractional test-meal method involves the quantitative chemical examination of the variations of both acidity and chlorides. In routine practice, however, full investigation is made of the acidity, but scant attention is usually paid to chlorides, though their importance is obvious. The two factors really go hand-in-hand, for many of the acidity curves can have but very little meaning in the absence of chloride determinations. For instance, the absence of free hydrochloric acid cannot by itself distinguish between an achylia and an achlorhydria due to complete neutralisation, nor, at the other extreme, can mere evidence of a hyperchlorhydria differentiate between hypersecretion and defective neutralisation. Such considerations have been frequently emphasised, notably by Bolton and Goodhart[1] and Baird, Campbell, and Hern,[2] and need not be elaborated here. It must be assumed, therefore, that the determination of chlorides is omitted on account of the analytical difficulties explained below. Indeed, analysis greatly needs simplification, and this paper presents a method which avoids long and difficult technique.

Estimation of Chlorides.

(1) *Total Chlorides.*—The standard method of estimation is to render the sample alkaline, evaporate to dryness, incinerate, and finally determine the chlorides by Volhard's method. The preliminary process takes time and the incineration requires cautious manipulation, patience, and skill. A Volhard titration on the original fluid is vitiated by the presence of protein, but this can be eliminated by the simple expedient of enormously increasing the proportion of nitric acid to test-meal sample in the mixture to be titrated. The whole determination is carried out in one operation, requiring no more than a simple titration of the Volhard type, and in less than one-tenth of the time formerly occupied.

Method.

Take up 0·2 c.cm. of filtered fluid in a blood pipette, carefully discharge this amount into 3 c.cm. of pure nitric acid contained in a wide test-tube, sucking up the acid two or three times to wash out the pipette. Add 1 c.cm. of N/30 silver nitrate solution, and then 4 c.cm. of pure acetone; the latter gives a sharp end-point. Mix, and after adding three drops of a saturated solution of iron alum as indicator, titrate finally from a 5 c.cm. microburette with alcoholic ammonium thiocyanate, previously standardised against the silver nitrate. (Ordinary aqueous thiocyanate of N/10 strength diluted with two volumes of alcohol is a suitable solution.)

Calculation.—Using solutions of exactly N/30 strength, if x be the number of c.cm. required in the titration, then $(1-x)\times\frac{100}{0\cdot2}\times\frac{1}{3}$ gives the degrees of total chloride (i.e., the number of c.cm. of N/10 chloride in 100 c.cm. of fluid). To convert this into percentage HCl multiply by 0·00365.

A series of comparative results, using the incineration method and the present one on samples taken at random from different test-meals, in each case performing the analysis on 0·2 c.cm. of fluid, is compiled in the table below. The figures represent degrees of total chloride.

Sample.	Incineration method.	Present method.
1	133·3	136·6
2	46·6	46·6
3	115·0	115·0
4	80·0	81·6
5	27·6	27·6

The methods agree within the limits of experimental error.

(2) *Mineral Chlorides.*—In the presence of an appreciable amount of free hydrochloric acid it will usually be sufficient to calculate the value of th mineral chlorides as the difference between the tota chlorides and the total acidity, for in such cases th free acid acts as a check to fermentation and th amount of organic acid is negligible. In other case it may be necessary to analyse for mineral chloride For this purpose no departure can be made from th principle of the generally accepted method. Incinera tion—without previous neutralisation—is the essentia feature, but the method as given in the text-books i unnecessarily long, because too much material i evaporated to dryness and then incinerated. Tim can be saved without loss of accuracy by taking one tenth of the usual amount of fluid. Moreover, direc tions are not, as a rule, precise enough as to th conditions under which the combustion should b performed. A Bunsen burner playing directly upo the ignition crucible to give a dull red heat i commonly recommended, but when no more than " dull red heat " is employed an appreciable amoun of chloride is lost by volatilisation. This error does no arise if a fine iron gauze is interposed between th crucible (which should be thin-walled) and the flam and the ignition is expedited if a Meker burner i substituted for the ordinary type of Bunsen. Th entire organic matter in 0·2 c.cm. can by this mean be safely incinerated within five minutes.

Method.

Take 0·2 c.cm. of fluid and discharge it into a porcelai crucible, washing out the pipette with three or four drop of distilled water introduced from a second pipette Evaporate to dryness on a water-bath, and incinerate a described, placing the cover over the crucible for the initia stage. The process is complete as soon as the whole of th black carbonaceous material is destroyed, leaving a grey ash Allow to cool, then take up the residue in 2 to 3 c.cm. c distilled water, and add an equal volume of nitric acid followed by 1 c.cm. of N/30 silver nitrate. Finally ad acetone and iron alum as in the previous method, an complete the titration in the usual manner.

Estimation of Free and Total Acidity.

There is little scope here for simplification, as th method usually adopted (Töpfer's) is one of th simplest of all chemical procedures. The alternativ put forward involves only a minor alteration of tech nique, but most of those to whom the author ha privately communicated it have preferred it t Töpfer's. It replaces Töpfer's two indicators b thymol-blue (thymol-sulphone-phthalein). A fe years ago Cole and Adie[3] elaborated a method c using this indicator, but their contentions wer subjected to well-founded criticism by Ryle,[4] whos essential point is, in effect, that the refinements c their method accomplish nothing clinically whic cannot equally well be achieved by simpler mean But, stripped of these refinements, it provides th basis of a method which is extremely simple—viz when the titration of the free HCl is carried to th point where the red tint, given by the indicator in th presence of mineral acid, just disappears. The assump tion, accurate enough for all practical purposes, is tha only the free acid reacts with the alkali up to th point. Continuation of the titration to the poin of first appearance of the blue colour gives the measur ment of the total acidity. (The significance of thes colour changes will be made clearer by reference to th paper of Cole and Adie.)

Method.

Pipette 2 c.cm. of filtrate into a test-tube and add thr drops of a 0·1 per cent. solution of thymol-blue. In the presen of free HCl the mixture will appear red. In this case titrat with N/10 sodium hydroxide from a 5 c.cm. microburett to the point where the red tint is no longer perceptibl noting the amount of alkali added (x c.cm.). Continue th titration through the range in which the mixture is yellow until the point where it turns sharply blue, now noting th whole of the amount of alkali added from the beginnin (y c.cm.). Then $50x$ gives the degrees of free acid and $5($ the total acidity. If on first adding the indicator the flui appears yellow, no free HCl is present, and the titration simply performed for total acidity.

No comparative figures need be cited. For obviou reasons the three methods discussed give practicall

ıtical results where the amount of protein in solu- ı is very low, a condition which obtains in nearly fractional test-meal samples. However, as Cole ntly pointed out,[5] in the resting fluid, where the tein tends in some cases to be relatively high, a repancy would arise under such circumstances ween the results obtained by the methods of Cole Adie, and Töpfer, the inaccuracy—the more reciable the greater the protein content—being the side of the Töpfer method. Here closer ement with the exact values would be attained using the present technique instead of Töpfer's, on the basis of principles enunciated in the paper ole and Adie, this would follow from the fact that end-point of the initial titration (pH 2·8 approx.) termediate between that of Cole and Adie (pH 2·0), that of Töpfer (pH 4 approx.).

n this score, therefore, as well as on account of its plicity, the thymol-blue method would seem ified.

Summary.

) An easy and rapid method is described for the mation of total chlorides.

) Considerable saving of time and labour results n the estimation of mineral chlorides is conducted micro-scale under the conditions stated.

) A method devised to take advantage, in the iest manner, of the colour changes of thymol-blue, referred to Töpfer's method of estimating free rochloric acid and total acidity.

THE MEINICKE MICRO-REACTION.

DAVID PRENTICE, M.B., CH.B. GLASG.,
ASSISTANT MEDICAL OFFICER, COUNTY MENTAL HOSPITAL, WHITTINGHAM.

HE diagnosis of syphilis in patients admitted to a tal hospital is a matter of some importance in of its possible ætiological influence on their hosis. Ordinary clinical examination is fairly tive in discovering general paresis and cerebro- al syphilis, but practically all the cases of latent ilis go undiscovered unless a Wassermann or r serum examination is performed. It is rious, and sometimes very difficult, to withdraw gh serum for a Wassermann in resistive or trouble- e cases, children, and those whose veins are ly developed, and the need for a test that would iate these difficulties has been felt for some . The Health Committee of the League of ions, in its report on the sero-diagnosis of syphilis penhagen, 1923), stated that "the flocculation s cannot at present replace the Bordet-Wasser- n test," but reported favourably on their bility, and mentioned the simplicity of the nicke turbidity reaction. Unfortunately, all e tests require a considerable amount of m. Micro-methods for the Sachs-Georgi test e devised by Scheer and A. H. Priestley,[1] and the Kahn reaction by B. S. Kline and A. M. ng,[2] and by R. L. Kahn himself. Weidainz rted a micro-method for the Wassermann tion. In most of these, however, there arose problem of inactivating a small quantity of m, and the Kahn micro-method involves the culty of measuring small quantities of serum by ns of capillary pipettes.

1 1923 the late Paul Dohnal[3] discovered a micro- hod for the Meinicke turbidity reaction. This was simplified and improved by Meinicke[4] in 1925. The practical value of the test has been amply proved by the investigations of Dohnal, Unter- steiner, Rietschel, Meinicke, and others. So far there has been very little work done on it in this country or in America, though it is extensively used on the continent. The Meinicke micro-serum reaction was first tried at this hospital over a year ago, and we are now in a position to give an opinion on its reliability and utility.

Technique.

1. *Serum.*—This is collected from a finger-prick and the blood run along a capillary tube 10 c.cm. long by 1 mm. inside diameter. Two-thirds of the tube are filled and the empty end sealed by a flame, taking care that the blood is not heated. Only if the capillary is to be sent away does the other end require sealing with wax. The tube is now left for a few hours in a cool place in a horizontal position and then centrifugalised towards the sealed end. The clear serum collects in the centre and is ready for use when the tube has been filed and broken and the contents tapped or blown on to a clean numbered slide.

2. *Antigen.*—Meinicke uses a cholesterin-free extract of horse heart muscle with the addition of balsam of tolu. One c.cm. of this is placed in one test-tube, and in another is placed 10 c.cm. of a 3 per cent. saline solution, to which pure sodium carbonate in the proportion of 1 to 8000 has been added. The two are placed in a water bath at 40° to 45° C. for ten minutes and then mixed by pouring rapidly three times from one to the other. The diluted extract is poured into a warmed porcelain crucible and covered with a watch glass. It has a yellowish tinge and is somewhat opalescent. As it rapidly becomes more opaque it should not be kept longer than ten minutes, in which time from 10 to 15 sera can be mixed with it.

3. *Mixing.*—Two platinum eyelets are used for this mixture. They are measured so that one loopful of the larger contains exactly five times as much as the smaller. The larger, about 5 mm. in diameter, is attached horizontally to a small porcelain stand, and a loopful of the diluted extract is taken on it. On the smaller, which is about 2 mm. in diameter, serum is taken. By passing this one through the lumen of the larger a 1 in 6 dilution of serum with diluted extract is accurately and easily made. The extract and platinum eyelets may be obtained from Dr. Meinicke's laboratory, Elberfelder Str. 74, Hagen, Westphalen, Germany.

4. *Examination.*—Both dark-ground and hanging-drop preparations of the mixture are made and examined within two hours. As several specimens are examined at once no other controls are needed. With the dark-ground illumination, using weak ocular and strong dry objective, a negative reaction shows an even greyish field, full of tiny gaily dancing dotlets. In a positive reaction the field is black, empty, and quiet, and very few dotlets are seen. The hanging-drop preparation is made in the usual way on a hollow slide, using a small loopfulof the mixture. The edge of the cover-slip should be vaselined to prevent evaporation. Here all the planes are optically empty in a negative reaction, save for the almost infinitesimal dancing particles, which are practically invisible. In a positive reaction agglutination occurs, and the clumps, which are at first evenly distributed, gradually sediment towards the lower pole. Blood corpuscles, fragments of dust and bacteria, if present, can be distinguished from true agglutinations by their shape and colour.

For some time now we have dispensed almost entirely with the dark-ground illumination, finding, as Meinicke himself does, that sufficient information can be gathered from the hanging-drop preparation. Our only fresh observation is that a delayed positive reaction has been noted on two occasions, so that it is advisable to re-examine the slides eight or nine hours after the test has been completed. The blood is collected by a trained nurse. Eight or ten of the capillary tubes are sent over to the laboratory at a time, and within a few hours the results of the examination can be sent to the medical officer concerned. Where a positive reading is found, a confirmatory Wassermann test is always performed. All glassware should be absolutely clean and free from grease, and the room temperature for the test should be about 20° C. The atmosphere should be humid.

Experimental Results in a Mental Hospital.

The sera of over a thousand patients have been tested. In 429 of these the Wassermann has been done as a control, and there is an agreement between the

results of the two tests in 93·3 per cent. of the cases. The main source of disagreement between the readings was in those general paralytics whose serological findings had undergone modification after a course of treatment by malarial inoculation and tryparsamide. The test has been performed on all new admissions since June 1st, 1926, and the numbers diagnosed as syphilitic between then and May 31st, 1927, make a most interesting comparison with the corresponding numbers for a year prior to the institution of a routine serum examination.

1925.		*1926–27.*	
Admissions.	Syphilitic.	Admissions.	Syphilitic.
Male .. 260	.. 32 (12·3%)	Male .. 264	.. 58 (21·9%)
Female .. 209	.. 9 (4·3%)	Female .. 190	.. 17 (8·9%)

Of the male admissions in 1925, 30, or 11·5 per cent., were general paralytics. The remaining two cases were of cerebro-spinal and meningo-vascular syphilis. On the female side seven of the nine, or 3·3 per cent., were general paralytics, and of the remaining two cases one was of cerebro-spinal and the other of meningo-vascular syphilis.

In the 1926–27 period the diagnosis of the 58 men and of the 17 females, according to their mental state, was as follows:—

MEN.		WOMEN.	
General paralysis of the insane	43	General paralysis of the insane	5
Meningo-vascular syphilis ..	2	Meningo-vascular syphilis	1
Dementia præcox	3	Dementia præcox	2
Recent and recurrent mania	3	Insanity with epilepsy ..	1
Manic-depressive psychosis	1	Imbecile	1
Senile dementia	1	Secondary dementia (cerebral hæmorrhage)	1
Insanity with epilepsy ..	2	Acute melancholia ..	4
Recent melancholia ..	1	Recurrent mania	1
Confusional insanity ..	1	Delusional insanity ..	1
Paranoia	1		

The very marked increase in the incidence of those diagnosed as syphilitic is most significant, and constitutes a strong plea for the more general adoption of this or some similar method of examination. In practically none of the cases, save those suffering from general paresis or meningo-vascular syphilis, could syphilis have been diagnosed without a blood test, as none showed any typical lesions.

The part played by syphilis in the ætiology of the other psychoses, and the therapeutic effect of anti-syphilitic treatment, is not a question which I propose to discuss at present. It will be noted, however, that if the general paralytics are excluded only 6·7 per cent. of the remainder of the patients gave positive blood readings at the time of admission. The Royal Commission for Venereal Disease estimated that 10 per cent. of the urban population of Great Britain are suffering from syphilis.

Kovács,[5] of the State Asylum for Children, Szeged, Hungary, reports very favourably on his experience of the test when dealing with infants. He resorts to a Wassermann only when the individual reactions of the mother and child give opposite results. The test, therefore, would probably be of great service in pediatric work. It is not suitable for the general practitioner, as he has not the time or material to carry out the routine.

Summary.

The Meinicke micro-reaction, as used in this hospital, has proved a very serviceable and reliable test. It gives a high percentage of agreement with the Wassermann, and has almost doubled the number of those diagnosed as syphilitic.

My thanks are due to Dr. R. M. Clark, medical superintendent, who has supervised the test throughout for permission to publish these results, and to Mr. A. H. Fann, senior laboratory assistant, to whose careful technique it owes much of its success.

Clinical and Laboratory Notes

A CASE OF FACIAL NEURALGIA ASSOCIATED WITH PULMONARY ABSCESS.

BY R. C. HUTCHINSON, M.D., D.P.H. MANCH.
LATE MEDICAL SUPERINTENDENT OF THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, VENTNOR;
AND
J. S. B. STOPFORD, M.D. MANCH., F.R.S.,
PROFESSOR OF ANATOMY IN THE UNIVERSITY OF MANCHESTER

THIS case is considered worthy of record on accou of the rare distribution of pain.

The Case Related.

The patient, a woman aged 39, was admitted to t Ventnor Hospital on April 17th, 1925. She gave a histo of slight hæmoptysis at the age of 10 years. From 19 onwards she had a cough and occasional attacks of staini of the sputum. In April, 1917, she had pneumonia of t left upper lobe with a very slow convalescence, a high te perature persisting until October of the same year. January, 1918, another attack of pneumonia occurre affecting the same part of the lung and again followed slow convalescence. In March, 1924, one of us (R. C. H saw this patient with a definite pneumonic consolidati of the left upper lobe. From this time onward she had very troublesome cough, slight fever running up to 9 and 100° F. nightly, and two ounces of sputum daily negati for tubercle bacilli. From 1919 till April, 1925, repeat attacks of slight hæmoptysis had occurred. On admissi on April 17th, 1925, there were signs of a cavity in t lower and anterior part of the left upper lobe, such sig being present in the fourth and fifth spaces and occupyi the normal area of cardiac dullness. The sputum was f and had increased to three ounces daily. There was clubbing. X rays showed a large cavity present in the lov and anterior third of the left upper lobe, probably adhere to the pericardium.

On April 27th a left-sided artificial pneumothorax w induced and continued, but the result was not satisfacto the X rays showing a rigid-walled abscess cavity wh showed no sign of collapse, although the peripheral lu was well collapsed round it (see figure). There w considerable mediastinal dislocation. On July 30th defin clubbing was noted. Thoracoplasty was suggested refused. The pneumothorax was maintained as the patie appeared to be more comfortable during its continuan In August a broad single diaphragmatic adhesion was not which appeared to pull on the abscess cavity. This w thought to be a possible additional cause of the troubleso cough, and with a view to eliminating its traction Harold Burrows performed a left-sided phrenicotomy Sept. 20th, 1925. A note, made at the time of the operati reads that something less than ½ in. of nerve was resected.

The X ray report on Oct. 3rd stated: "The diaphra has not lifted in the chest. It shows paradoxical movem —inspiratory rise, very slightly expiratory fall. There apparently a very definite lateral decrease in the size of cavity." On Jan. 1st, 1926, the notes read: "Patient neuralgic pain in the face which started last night. To-d has definite neuralgia of the left inner canthus and alo the left nasal bone. Pain is most severe in the left na bone and occasionally there is a stabbing sensation alo the inferior margin of the orbit. The left eye wat when the pain is severe. There is also pain and tendern on pressure over the upper border of the left trapezius a in the hollow of the left shoulder."

The neuralgic pain decreased considerably after cough and consequent expulsion of the contents of the cavity, a on some occasions disappeared altogether for a time. At a quiet night with little coughing the pain was more seve for example, on Jan. 7th, 1926, the notes read: "Pati has not coughed during the night and now has intense p in the face and nose." The daily sputum varied fr 3 to 24 ounces. The neuralgia persisted until de occurred on March 20th, 1926. The relationship betw the pain and decrease of expectoration was definite, accumulation of secretion in the lung being invaria associated with the onset of neuralgia.

Cause of the Referred Pain.

Any explanation of the cause of the facial neural and reflex pain in the shoulder must be founded the assumption that the phrenic nerve was at t time capable of conveying afferent impulses to t

ntral nervous system. The mediastinal pleura is pplied with branches from the phrenic nerve, and e clinical history suggests that this nerve was agged upon, or otherwise stimulated by the abscess vity when this was full of pus. It is difficult, owever, to derstand how pulses could conducted to e central ner- us system by ie phrenic rve when it is called that lf an inch of length was cised in the ck about three nths before e onset of the in.

In the absence a post-mortem s only practic- le to consider e possibilities, which there pear to be ree. The first that some bres have ssed the gap d descended e distal seg- ent of the rve to reach e vicinity of e abscess. servations on the re- neration of ripheral rves under ilar circum- nces render this explanation highly improbable, ce the interval between the two segments s so great. This explanation cannot, however, absolutely excluded. The second possibility that fibres from the distal end of the proximal gment have sprouted out into the surrounding ep tissues, and some have passed down between e fascial planes in the thorax and so extended to e neighbourhood of the abscess. This appears to quite a reasonable possibility, as after section a nerve it is well known that fibres grow out and ll travel along fascial planes, although most of the res usually cause a reaction in the neighbouring sues which leads to the creation of an "end bulb." serious objection to this hypothesis is the short ie which elapsed between the operation and the set of the pain; it appears hardly long enough to rmit regeneration of nerve-fibres from the level the section to the abscess cavity. The third, and haps the most likely, explanation is the occurrence an accessory phrenic nerve. This arises usually m the fifth cervical nerve, and after passing in front behind the subclavian vein joins the main phrenic nk near the thoracic inlet or in the thorax. This nction between the phrenic and the accessory renic would be distal to the level of the section of e former, and therefore a pathway from the pleura to e cervical spinal cord would persist after the opera- n. The occurrence of an accessory phrenic nerve is ficiently common to render this suggestion highly obable.

Relation of Phrenic and Trigeminal Nerves.

It is easy to understand the referred pain in the oulder, since it is only necessary to refer to the con- xions between the central terminations of the essory phrenic and the central connexions of the scending cutaneous branches of the third and urth cervical nerves which are distributed to the skin in the regions where the pain was experienced. The occurrence of the neuralgia in the upper part of the face is of greater interest and must involve connexions between the phrenic and the central terminations of the trigeminal nerve. It is well known that the spinal nucleus and tract of the latter descends well into the cervical cord, at least as low as the second cervical segment, so that the central fibres of the two nerves are very near and likely to be connected. It has been shown by anatomical and clinical researches [1] that the caudal part of the spinal nucleus of the fifth nerve receives fibres only from its ophthalmic division; the most caudal part would be the segment nearest to the central fibres of the phrenic, and this probably explains the limitation of the neuralgia to the distribution of the ophthalmic division of the trigeminal nerve. A minor point of interest is the development of clubbing of the fingers and toes in sixteen weeks.

Radiogram showing the condition of the lung after artificial pneumothorax and before phrenicotomy. The large pulmonary abscess with a fluid level is not compressed, although the peripheral lung is well collapsed. There is considerable mediastinal dislocation, and a broad basal adhesion is present.

A somewhat similar case has been reported by Ricaldoni [2] in connexion with artificial pneumothorax treatment. In this instance the neuralgia was more widespread and this was considered to be due to the refilling of the pleural space. It disappeared with the discontinuance of pneumothorax.

A CASE OF TRAUMATIC PANCREATITIS.

BY HERBERT R. MAYO, M.B., B.CHIR. CAMB.,
HON. MEDICAL OFFICER, GENERAL HOSPITAL, GREAT YARMOUTH;
AND
EDWARD A. ELLIS, M.B., B.CH. DUB.,
HOUSE SURGEON TO THE HOSPITAL.

A CASE of traumatic pancreatitis has lately been under our care in the General Hospital, Great Yarmouth. Medical literature in Great Britain has few records of such cases, the only one recently recorded to our knowledge is that of Waring and Griffiths.[3] Therefore details of our case may be of interest.

The patient was a Scotch girl of 18, from Stornoway, one of the fish-workers visiting this port during the herring fishing season, in the autumn. She was a strong, healthy girl with no history of previous illness or accident. On Oct. 14th she was caught between a wall and a lorry moving sideways towards her, which nipped her at the level of the upper half the abdomen. She was rapidly conveyed to hospital and admitted between 8 and 9 P.M. On examination,

[1] The Function of the Spinal Nucleus of the Trigeminal Nerve, by J. S. B. Stopford, Journal of Anatomy, 1924-25, lix., 120.
[2] Pneumothorax artificiel et névralgie de la face, A. Ricaldoni, Bull. et Mém. de la Soc. Méd. des Hôp. de Paris, 1921, 3e sér., xlv., 802; Abstract in Tubercle, March, 1922, p. 266.
[3] Waring, Sir Holburt, and Griffiths, H. E.: Brit. Jour. Surg., 1923-24, xi., 476.

no abrasion or bruise was present on the abdomen or elsewhere. She was suffering considerably from shock, with some diffuse abdominal pain. Temperature subnormal and pulse, 84, was thin. No signs of any gross lesion. She received the usual treatment for shock and was kept under careful and constant observation for any sign of internal hæmorrhage. The next morning the temperature was 98° F. and in the evening rose to 99°. She said she was free from pain and her general condition was greatly improved. The pulse was fuller. On the 16th her morning temperature had risen to 101° and the pulse-rate to 100, and she complained of vague abdominal pains, but the temperature fell to 99·4° in the evening and respirations increased to 40. On the 17th the temperature continued to fall, but the pulse increased in frequency, though still of good volume. The pain increased and was accentuated by ingestion of food and relieved by vomiting. The exhibition of bismuth and soda had no influence on the pain which was referred to the epigastrium.

For the next two or three days the pain continued at intervals, but the pulse and respirations diminished in frequency. The temperature was somewhat erratic but fell to normal with a pulse-rate of 84 and respiration-rate of 26 after a copious stool, which resulted from an enema given on Oct. 20th. In the evening the temperature rose to 101·6° with pulse of 100, but in the morning of the 21st it fell to normal again with pulse-rate 80 and respirations 24. During the next three days, though there was nothing alarming in the pulse and temperature, her condition became worse. She had a bad colour and the pain became so bad that morphia was given to relieve it on the 24th, when operative interference was suggested. As her condition was much worse on the 25th she agreed to an operation. The left upper rectus was rigid and very sensitive to touch or pressure. There was some general tenderness over the abdomen and some distension. The abdominal pain was very marked, but it was most acute under the left upper rectus. The respirations had risen to 46.

Laparotomy was performed on Oct. 25th. As the bulk of the pain and tenderness was on the left side, a paramedian incision was made through the left rectus. There was no sign of any damage to the abdominal wall. On opening the peritoneal cavity a little free turbid fluid was noted, but there was no escape of gas or marked odour. Two or three small areas of fat necrosis were seen close to the stomach, which was undamaged. The pancreas was found to be swollen with recent adhesions at its head. To obtain more easy access to the head of the pancreas and the gall-bladder a transverse incision was made across the middle line and through the right rectus, above the umbilicus from the middle of the primary incision. The gall-bladder was tense and somewhat hidden by recent adhesions. On gently freeing the gall-bladder with swabs pus was seen to ooze up from the direction of the head of the pancreas. The gall-bladder was freed from its adhesions and pus removed with swabs. A rubber tube was sewn into the gall-bladder, a corrugated rubber and gauze drain to the head of the pancreas, and drainage-tubes to the right kidney pouch and Douglas's pouch were inserted. The primary incision was sutured and all four drains concentrated in the middle of the second incision. After the operation she was in a state of great collapse with feeble pulse of 120, sighing respiration, and bad colour. Camphor and ether were administered subcutaneously and four-hourly rectal salines.

The next day, Oct. 26th, as her condition still remained very serious, five units of insulin were ordered twice daily, with glucose added to the salines. On the 27th her condition improved slightly, but she had tympanites, which was much relieved by a turpentine enema, which was followed by a loose, copious stool. On the 28th the drainage-tube to Douglas's pouch and the right kidney pouch were removed and as hiccup appeared eserine gr. 1/100 was given four-hourly. On the 29th she was much improved, so eserine was discontinued; but as the improvement disappeared eserine was again given.

During the subsequent period there was a free discharge of pus from the drain to the pancreas and the tube in the gall-bladder which at first discharged pure bile, then discharged bile mixed with pus and, later, almost pure pus. The skin round the drain was protected with zinc ointment and did not suffer from irritation as in the case reported by Delatour.[4] Her condition was curiously dependent upon the administration of eserine. When this was discontinued she rapidly became much worse, the pulse became feebler, though the rate did not increase much, her colour became bad and she had marked depression and lethargy. Simple enemata were given every alternate day with invariably good results.

On Nov. 5th the stitches were removed. On the 16th the tube from the gall-bladder and the drain from the head of the pancreas were removed, but bile and pus mixed continued to discharge from the sinus in gradually decreasing amount. As rectal salines were discontinued glucose w given by the mouth. From Nov. 26th her condition steadi improved, with colour returning to her cheeks.

General massage was instituted to improve her muscul tone and general metabolism on Dec. 7th. On the 16t the amount of insulin was reduced to five units once a d before the midday meal and this was discontinued the 22nd. On the 13th she had been allowed to sit in chair, and day by day she was given further opportuni for exercise in walking about the ward, and rapidly improve The bowels acted normally without enemata from Dec. 27 onwards. She was discharged from hospital on Jan. 7t 1928, with a perfectly healed scar and no sign of sk irritation around it. She stayed in the town a few da and then returned by easy stages of one day's travelling far-off Stornoway. Nearly a month later she wrote a stated that she had continued to improve after reachi her home and was rapidly regaining her strength.

The only similar case of which we can find a record the one of Delatour,[4] but there are many poin of difference. They agree in the age and incide and amount of shock after operation and pain exhibition of food. They differ in the amount initial shock, irritation of skin by discharge fro drainage-tubes, and subsequent formation of a cys

The points to be noted in this case are: (1) T injury was not caused by a direct blow, but by sliding squeeze, producing a shearing effect on limited portion of the abdomen with no local mar on the skin. (2) The severity of the immedia shock differing from the cases reported by Wari and Delatour, and we suggest that this may have be due to direct irritation of the solar plexus. (3) T tardy development of the symptoms directly d to the pancreatic lesion. (4) The free discharge pus from the gall-bladder drain. (5) The exhibiti of insulin on the theory of rest and regeneration the pancreas and to assist in the absorption a utilisation of glucose, the most easily administer nutriment. (6) The most ready and constant respon to hypodermic injections of eserine when su generally accepted remedies as strychnine, camph and ether and brandy were of no avail. (7) Despi the use of four separate drains and a discharge ther from lasting some five weeks, there was a very sou abdominal wound, and as the bulk of this is above t umbilicus the risk of subsequent hernia is almo negligible. (8) There was no sign of any cy formation.

New Inventions.

A CARBONIC ACID SNOW APPLICATOR.

In the application of carbonic acid snow warts, moles, and small nævi the protection of t surrounding skin always presents a difficulty. T pressure of the snow pencil creates a temporary crat the sides of which are inevitably frozen and blister so that the consequent scar is larger than desirab Moreover, it is not easy to apply it exactly to t tumour. To obviate these drawbacks I have had made to my design the applicator here illustrated. It consists of a circle of plate glass 2 in. in diameter, with an axial tube projecting 1 in. on one side, $\frac{1}{16}$ on the other. A solid glass rod to each packs the snow easily and tightly. T lumen of the tube is exactly applied over the sm tumour and the plate held in position by two fingers one hand, while the desired degree of pressure maintained by a finger of the other on the end of t rod. The applicators are made in four sizes, $\frac{5}{32}$, $\frac{7}{32}$, and $\frac{1}{4}$ in. Nævi of more than $\frac{1}{4}$ in. in diameter c be treated with an unprotected pencil. I have us them with the greatest satisfaction both in priv and in hospital practice. The intense cold does crack or even chip the glass.

Medical Societies.

FEDERATION OF MEDICAL AND ALLIED SERVICES:

COUNCIL OF INDUSTRIAL MEDICINE.

THIS Council met on March 2nd under the chairmanship of Dr. D. A. COLES to discuss Industrial Accidents and Rheumatism. The Chairman explained that the Council's objects were to gather all the available knowledge and place it at the disposal of employers of labour with a view to reducing the great economic loss and human suffering caused by accident and disease. The International Congress for Industrial Accidents and Diseases, of which the Council was the authorised English Committee, would meet this year in Budapest.

Industrial Accidents.

Prof. E. L. COLLIS set out the advantages of treatment at a works clinic in saving both time and compensation costs. Whereas the ordinary surgeon dealt only with wound healing, the industrial doctor was skilled in the restoration of specialised function. The panel doctor to whom an injured workman was sent had either to imperil the healing of a wound by taking down the dressings, or to make himself responsible for a wound of which he knew nothing, and which might include cut tendons or nerves. The works doctor could prescribe suitable half-time work, and administer that sovereign remedy, "a hair of the dog," at a much earlier stage than the panel doctor. A clinic which organised treatment from first-aid to care saved literally half a firm's compensation charges.

Sir PERCIVAL WILKINSON said that the object of the Order of St. John was to get as many men and women trained in first-aid as possible in all the pits, factories, and industries of the country. The "responsible person" whom the Factory Acts required to be in charge of a first-aid room should be properly defined by any new legislation, and his qualifications ensured by inspection; there should be a first-aid supervisor for each big floor and each building. In the best-run pits there was an organisation on every level and for every shift. There was an average of 62,000 accidents a year on each of the four main railways, and one of the most up-to-date Doncaster pits treated 80 accidents a year at pit-head.

Dr. DRUMMOND SHIELS spoke of the efficiency of the first-aid work on the railways, and the praiseworthy way in which the directors encouraged it, and Dr. SALISBURY SHARPE described the system on the Great Western Railway by which 10 per cent. of the men were trained in first-aid and their skill maintained by yearly courses.

Dr. ALFRED SALTER stated that in his work as medical officer to three trade-unions he found a constant source of difficulty in directing injured men to places where they could obtain after-treatment for, say, traumatic arthritis. A certain amount of massage, radiant heat, and the like was available at the London hospitals, but the enormous industrial dormitories on the fringe of London remained unprovided for, and unless the patient travelled up every day it was almost impossible to find treatment. This was often physically or financially impracticable. The result was that patients who might have been at work six weeks after an accident went on drawing compensation for months or years. The remedy he suggested was the establishment of central district and local clinics financed by a levy on the companies insuring against industrial accidents. Another great difficulty was that of finding light work by which a convalescent could be rehabilitated, and he saw no solution but the provision of gymnastics at these suggested industrial clinics.

Mr. HENRY LESSER, President of the National Federation of Employees' Approved Societies, extolled the system whereby in some large works a "jury" of representatives of the men and management sat to inquire into the cause of every accident that took place and to suggest means for preventing its repetition.

Mr. MAURICE SALMON, of Lyons', and Mr. C. R. PITT, of Debenhams', testified to the value of a clinic in a large factory and a department store respectively.

Dr. N. HOWARD MUMMERY compared the respective efficacy of the treatment of accidents at the factory, in hospital, and by private and panel doctors, in favour of the first method. In his own clinic, serving a factory staff of 6200, the records for the three months ending February, 1928, showed 2909 new injuries of all kinds. In only 179, just over 6 per cent., was any working time lost. 4716 out of 5060 redressings were done during continuous employment. The saving of working time and compensation was enormous.

Industrial Rheumatism.

Dr. FORTESCUE FOX said that the campaign against rheumatic diseases was now international. Their investigation and treatment presented big problems, and he would despair of success unless the many interests concerned—medical, official, industrial, and social—gave support to the Red Cross Society's effort to found a demonstration clinic in London. Among its other functions this clinic would deal with early cases which were at present left untreated, and it would also aim at ameliorating cases which were now regarded as incurable, thus preserving the usefulness and earning capacity of large numbers of workers.

Mr. LESSER bore witness to the effectiveness of continental clinics for the out-patient treatment of rheumatism. Statistics compiled by the insurance societies and employers showed that men returned to work much sooner than formerly. The clinics which the British Red Cross was proposing to set up would prove a boon to thousands of sufferers from this disease.

Dr. M. B. RAY dealt with the actual methods by which rheumatic diseases—he used the plural advisedly—should be treated. These complaints were profoundly influenced by climatic and environmental changes, and some people were more liable to them than others. The only possible inference was that the tendency was congenital. It had been found that the skin of rheumatically inclined persons was an insufficient protection against cold and damp, and although other causes, such as septic foci, played their part, the skin was the organ chiefly at fault in the production of these diseases. They occurred in certain persons who did not react favourably to their surroundings, and no organ was concerned so closely with the environment as the skin. Treatment should therefore be directed towards improving the activity of that organ, and should consist of hydrotherapy, manipulation, and exercise, in combination with heat, light, and electrical therapy. Up to the present time no concerted effort had been made to deal with this large body of sickness. Hospitals and spas could only deal with suitable cases who could travel to them. The British Red Cross Society proposed to bring the treatment to the patients, by establishing clinics accessible at all times in which patients could be treated after their working hours. Sufficient progress had already been made to start a demonstration clinic.

Dr. R. LL. J. LLEWELLYN said that he had been treating skins for 30 years and agreed with Dr. Ray's estimate of their importance. People were often asked how their bowels acted, but never how their skin acted, though it was equally important. In the prevention of rheumatism the care of the skin was the beginning of wisdom. It ought to be possible, and he thought it was possible, to "spot" potential rheumatic subjects, and these were the people towards whom preventive measures should be directed. It was useless to talk about preventing a disease that was already there. These subjects should be studied, not from the pathological, but from the physiological point of view, bearing in mind that the skin and the mucous membranes were the danger spots. The skin and the muscles were bound up reciprocally, and should interact with due balance.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF ANÆSTHETICS AND OBSTETRICS.

AT a combined meeting of these Sections on March 2nd Dr. CECIL HUGHES, President of the Section of Anæsthetics, in the chair, there was a discussion on

ANÆSTHESIA IN OBSTETRICS.

Mr. EARDLEY HOLLAND said that professional anæsthetists were now beginning to take an interest in the administration of anæsthetics in obstetrics, a branch which they had hitherto much neglected. The method used for this work, if it was to be generally adopted, must be simple and safe, and capable of being employed by those who had not had special training. It was necessary in this work that pain should be abolished, or materially diminished, over long periods of time, and the form of anæsthesia used must not lessen the force and frequency of the uterine contractions, nor endanger the life of the fœtus. Anæsthetics were used for two distinct purposes in this specialty: (1) to relieve the pain of labour; and (2) for obstetric operations, such as version and Cæsarean section. For the second purpose the most suitable anæsthetic was that which was best for operations in general; deep and prolonged ether anæsthesia, however, was undesirable for the fœtus, which was also very sensitive to morphia. This drug should not be given within two hours of delivery. He thought highly of stovaine, certainly for Cæsarean section, which it made almost bloodless.

Reverting to the relief of pain in ordinary or normal labour, Mr. Eardley Holland declared that every woman ought to be saved the pains of labour. The statement of the whole question by Simpson 81 years ago had not been improved upon since, and the only subsequent advance had been the Junker inhaler. If practising midwives could not alleviate the pains of labour, 75 per cent. of women must go on suffering in labour in this country, as that proportion were attended at the present time by midwives. This inability to relieve the pain of the mother was the great bar to the advancement of the midwife. He did not see any objection to midwives giving analgesic drugs, such as chloral and morphia. The anæsthetic requirements of the first stage of labour were different from those of the second stage. In the latter, especially in primiparæ, the pain was very severe. The pain in the first stage could easily be made tolerable by such drugs as chloral, or morphine and hyoscine together; but in the second stage a general anæsthetic was usually needed. Emotional conditions heightened the intensity of the pain, and the apprehensive state engendered by conversation about the perils of childbirth made it desirable to try to restore their confidence in the last months of pregnancy. The method of common use for anæsthetising these women was that of intermittent chloroform anæsthesia. This should not be given until the second stage had begun—certainly not until the first stage was nearing its end. As soon as it was evident that the pain of the uterine contractions was not being well borne, grs. 30 of chloral should be given or an injection of morphia and hyoscine. This, with a repetition of the hyoscine, carried the patient, with very little pain, on to the second stage of labour. At the onset of the second stage, chloroform was given by the Junker inhaler. This was not, he contended, sufficiently taught to medical students. The anæsthesia must not be deep enough to interrupt the uterine contractions. Under light anæsthesia, powerful bearing-down efforts were associated with perfect relaxation of the pelvic floor. There should be a deepening of the anæsthesia for the most painful part of the process of birth, when the head passed through the vulval orifice.

Dr. JOSEPH BLOMFIELD said the obstetrician tolerated, in labour, a condition of affairs—i.e., absence of anæsthesia—which he would not allow in any other surgical connexion. Even when an anæsthetic was used it was often left until too late, and was n skilfully administered. Every woman in labour shou be free from pain from first to last. The absence the anæsthetist from such a large proportion of the cases was simply due to the fact that he had not be asked to coöperate. In certain cases nitrous oxi and oxygen was the ideal anæsthetic, but it must administered by somebody familiar with the apparatu and generally home conditions were not very suitab for it. For some it was an inefficient anæsthetic, a these women would only become excited with it. H agreed with Mr. Eardley Holland that the anæsthet for general use was chloroform, as it was almo invariably successful. He had not had experience the synergistic method, which was advocated and us in the United States—namely, the use of morphia a magnesium sulphate, followed by ether and quinine p rectum. He had found that ethyl chloride was a ve useful drug when the pains began, and its effect cou be reinforced by very weak chloroform.

Mr. WILLIAM GILLIATT agreed that certainly wh the doctor was working with single-handed assistan chloroform was the favourite anæsthetic. Eth seemed to diminish the strength of the uteri contractions and so delayed the birth of the chil Not only had the woman in labour the right to saved pain, but the obstetrician preferred that t woman should be lying still, for then it was easi to keep the operation aseptic. Chloroform was mo potent and acted more quickly than ether; but ga and-oxygen, with the addition of a little ether, was be during the passage of the child's head. It stimulat rather than checked the uterine contractions and a vomiting was but slight. There was some danger chloroform poisoning if that anæsthetic were use and if any toxæmia was already present that dr might increase it. The danger of trouble was increas if the patient were given more than one kind anæsthetic for the labour and a complication. He ga details of five serious cases, two of which end fatally, one in 36 hours, the other in 15 hours. Wh spinal anæsthesia was used for a patient for wh inhalation would be dangerous, no inhalation shou be given at the same time. In his maternity wards now used ether.

Dr. H. A. RICHARDS said the choice of the anæsthe should depend on the state of the particular patie He agreed that if a patient had previously been giv an anæsthetic no subsequent anæsthetic shou contain chloroform. For a second anæsthetisati gr. 1/100 atropine should be given half an h beforehand, then ether. If the patient was accustom to being violently sick, nitrous oxide and oxygen shou be used when she seemed to be unduly apprehensi of pain. For Cæsarean section it was best not to g any chloroform at all. Twilight sleep did not co into the range of the discussion, as it was not anæsthetic. His objection to using ethylene in priva practice was that there was usually a fire in the roo and it was a very explosive substance.

Mr. H. E. G. BOYLE spoke highly of the skil administration of gas-and-oxygen by Dr. Wes Bourne at Montreal; from this he had gained t impression that it was one of the finest of all an thetics. After obtaining the patient's confidence could produce by this mixture a condition of analge in which the patient would do just what she was ask to. Certainly it did not diminish the propuls efforts of the uterus. When the woman bore do well it shortened the duration of the labour. Eth could be used just when the head was being bo and then a mixture of CO_2 and oxygen could be giv for a few minutes. He would like to see gas-an oxygen more used in obstetric practice in this count

Dr. H. BECKETT-OVERY said he did not kn whether specialists appreciated how much so patients suffered after their confinement—sometim for months or years after delivery. Even after uncomplicated confinement some women suffe severely from shock, and if it could be shown th there was a general anæsthetic which was available all purposes, it was, he considered, the docto

ounden duty to use it. In the case of women whose s was dilating rapidly he at once gave hyoscine and iorphine, a measure which seemed to quieten the motions, so that by the time the second stage was eached the patient was able to use the chloroform erself. He hoped that the old attitude that it was ot necessary to use an anæsthetic for women in abour had now passed from the profession for good. n quite 70 per cent. of the cases he did not think a mall quantity of an analgesic drug brought about any ppreciable delay in the birth process, and it was a onsiderable gain to the patient, as the head could e delivered without any laceration.

Dr. S. A. S. MALKIN (Nottingham) spoke of the ynergistic method—i.e., administration of morphia nd magnesium sulphate, followed by the rectal nstillation of ether and quinine in olive oil. The merican view of it was that only a small dose of iorphia was given and that the magnesium sulphate ept the action more effective and over a longer time. he quantity of ether needed was also small, and it as said that the administration could be rendered so utomatic that the constant attention of the obstet- ician was not required. He had used the method in) cases, of which 12 were entirely successful—i.e., ie patient slept between the pains and stirred only ith the pains. In some cases the woman had not nown when the child was born. In one case there as excitement, in two the method failed completely, one he gave the morphia rather late, the second age supervened quicker than he expected, and the ild was born blue. Now that he was better quainted with the technique he felt certain of curing a large percentage of successful cases with ie method, which, he was convinced, possessed dvantages.

SECTION OF ORTHOPÆDICS.

A MEETING of this Section was held on March 6th, r. W. ROWLEY BRISTOW, the President, in the air, when Mr. HARRY PLATT read a paper on the

TREATMENT OF ACUTE OSTEOMYELITIS.

he literature, he said, offered conflicting advice, ually based on very small series of cases collected er very long periods. The outstanding contribu- on to the subject in the last decade had been made Clarence Stau, of Toronto, who had recorded 7 cases at the Children's Hospital during 12 years. he greatest mortality occurred in the age-group –15, and was twice as great in males as females. Mr. att's series at Ancoats Hospital, Manchester, mbered 41 in five years. He then outlined the atomy of the blood-supply of growing and adult nes on which the infective process depended. he acute osteomyelitic process began in the meta- yseal cancellous tissue just under the epiphyseal sc, because of the "end-artery" system and ggish blood-supply. The focus rarely spread to the joint, but more often to the subperiosteal ace and thence along the surface of the shaft. he "gutter" operation had been based on the roneous belief that spread occurred early along e medullary canal. The Toronto school had shown at the cancellous tissue of the metaphysis offered nsiderable opposition to the spread of infection, d that the juxta-epiphyseal focus remained small d localised when the periosteum was extensively ripped. The medullary canal was invaded late, d through the Haversian canals from the sub- riosteal space. This fact had been established by e most convincing experimental, clinical, operative, d post-mortem observations in Toronto, and Mr. att had confirmed it in his own series. In older ildren there might be atypical localisation, especially the radius and ulna, and occasionally in the fibula, e infection reaching the bone by the nutrient artery d spreading up and down the medullary canal.

Early and Differential Diagnosis.

There were two main clinical groups: those in om local and constitutional signs appeared abruptly after two or three days prodromal period, a phase which might indeed almost be non-existent, and those in whom the prodromal stage lasted three or four weeks with important localising signs which all too often passed unnoticed. During the prodromal stage a tiny juxta-epiphyseal focus was smouldering. The signs were fixed pain at the end of a long bone and metaphyseal tenderness, which might be accompanied by intermittent limp and general seediness. In these cases diagnosis should be increasingly possible in the future, if the significance of the localising signs were more widely appreciated. In the next phase the signs became more insistent and bony swelling was added to them; the juxta-epiphyseal focus was just reaching the periosteal space. Unfortunately, this was often taken for some other acute infection, usually rheumatism. Yet there was a marked distinction between the joint pain, tenderness and muscular spasm of rheumatism, and the painful, thickened, tender metaphysis. It was important to decide whether indeed there was such a thing as acute monarticular rheumatism, and, if so, how common it was, in order that students might be taught to think first of acute osteomyelitis. An early exploratory puncture was a minor operation which did no harm if the diagnosis were not confirmed, and might save many lives and limbs. Special diagnostic difficulties and high mortality were presented by osteomyelitis of the flat and hidden bones. In the pelvis the ilium was usually affected, and there was early extra-osseous spread and large intermuscular abscess, or the infection might spread widely in the diplöe. Pain and tenderness might be absent or inconspicuous, and the condition should be suspected in any acute toxæmia without localising signs. There might be referred pain down the thigh, pelvic tenderness, or a sense of resistance between the trochanter and the iliac crest. Mr. Platt urged exploratory puncture without delay in every suspicious case.

Treatment.

The principles governing treatment were: (1) early and efficient drainage and early sterilisation of the wound; (2) avoidance of further devascularisation of infected and uninfected bone, and infection must not be introduced into uninfected areas during operation; (3) systemic infection must be combated by all forms of general and specific treatment, such as immune transfusion and intravenous antiseptic medication.

Operations could be regarded in terms of drainage. Subperiosteal and metaphyseal drainage in the early stages gave excellent results. Subperiosteal drainage alone was usually insufficient, and could only be regarded as a minor procedure of urgency in patients who were too ill for anything else. The cavity should be lightly sponged out, but no curettage should be done. Of Mr. Platt's 41 cases, 22 had been treated in this way and 14 had healed without sequestration. There was no justification for the "gutter" extension, which should be condemned as futile and dangerous. The gutter operation, or diaphyseal drainage, had its indications when the medullary canal and cancellous tissue were widely affected, as when the process had started in the centre of the shaft or in neglected cases of primary metaphyseal infection. Of the four cases so treated by Mr. Platt one had died and two had had extensive necrosis and chronic suppuration. On the subject of subperiosteal resection of the diaphysis Mr. Platt's mind was "open and to let." The procedure must compete satisfactorily with conservative operations if it was to be accepted. In theory it was better than the gutter operation for neglected cases when the shaft was riddled with infection.

Primary Resection.

Mr. ALEXANDER MITCHELL spoke of the importance of blood culture on admission. Simple incision was universally disastrous, except in the mild type of pneumococcal osteomyelitis. In an early case of septic osteomyelitis of a long bone he had found that

removal of a piece of the cortex for drainage gave a good intermediate, and in most cases a good end-result. Resection in subperiosteal infection had not received the attention it deserved. Extensive resection of the humerus, tibia, or femur was not, however, very satisfactory. His practice of resecting the whole length of an infected shaft must be regarded as an alternative to amputation. In 90 per cent. of cases, with careful after-treatment by extension and early muscle exercise, a good result would be ensured. It was very important to get the tibialis anticus, or interior muscles of the leg, to act early. Plaster or tight splints were almost sure to prevent regeneration, but if the limb were kept in a Thomas splint with a certain amount of extension, but not fixed in such a way as to prevent voluntary movement, regeneration was almost sure to follow. Two days after operation the packing should be removed and a periosteal suture done, except for a gap at each end for drainage-tubes. The bone should then be treated with eusol or flavine. Another argument against resection was the high mortality, but in a series of 70 cases treated during the last five years primary resection had been performed 13 times with only one death, a patient with active septicæmia. The total number of deaths was ten. The risk of removing a large sequestrum was much greater than that of a primary resection. Subperiosteal resection was not a routine treatment, but it had a place, and suitable cases could be recognised by the experienced surgeon. He had not seen any good follow blood transfusion in acute osteomyelitis. He had never seen a case in private practice, although he would expect the hospital child to be less liable to bone infection. He strongly agreed with the importance of impressing upon students the gravity of the disease and the need for early diagnosis, particularly of making a routine examination of the ends of the long bones in children with an unexplained rise of temperature.

Mr. ERIC LLOYD described a series of 29 cases from Ormond-street Hospital, all of which had been under his personal care. The *Staphylococcus aureus* was the cause in a very high proportion (19 cases) and was much more lethal than the streptococcus. Only one was due to the pneumococcus. Eleven had died. The lower limbs were involved far more often than the upper. None of the cases gave negative blood culture, and there was a high incidence of cardiac complications: pericarditis, pyopericardium, and ulcerative endocarditis. Treatment should be something between the "gutter" operation and the periosteal incision, leaving only a portion of the circumference to act as a splint. The pendulum had, perhaps, swung a little too far away from amputation. Blood transfusion and intravenous medication had been tried, without striking results. Some of the streptococcal cases seemed to make a remarkable recovery however they were treated, while some of the staphylococcal ones made no effort in spite of every kind of help. Diaphyseal excision had not been generally practised recently.

Mr. W. H. OGILVIE showed the records of 51 cases from Guy's Hospital from 1922–26. Acute osteomyelitis was one of the decreasing diseases. The preponderance of male cases was great, but varied in different localities. Sixty-eight per cent. of cases were between the ages of 8 and 15. The upper end of the tibia showed the greatest incidence, followed by the lower end of femur, lower end of tibia, and upper end of humerus. The mortality was 21 per cent., and 51 per cent. were discharged unhealed. Amputations accounted for 8 per cent., and 16 per cent. were sent out healed. There had been three cases of disease of the ilium, of whom one had died; the mortality from infection of the femur was low, because signs were earlier in that region. The series showed favourable results from radical ("gutter") operation. The mortality was not so much a question of treatment as of the virulence of the disease, which varied enormously. The average time between the onset of symptoms and admission was 7·4 days. The difference between the adult and childish type was shown strongly; in the adult the infection wa apt to be latent, the symptoms less severe, and th course much more favourable and quieter. Th average time in hospital was three months. Ninety two per cent. of the organisms were *Staphylococcu aureus*, admittedly the specific organism of oste myelitis in London; the Edinburgh figures differe from those of other centres. Joints were very frequentl affected, but this was more a feature of pyæmia tha of osteomyelitis as such. In severe cases the hea and pericardium were often attacked. It wa impossible by clinical means to tell the amount present or future necrosis, what bone was healthy and what would survive, and where resection shoul stop. Bone death was always liable to appear a the edge of the operative interference. Operatio should take into consideration the future proble of repair as well as the immediate problem of infectio All bone which did not die was a potential source bone cells, and wide resection might be harmfu He condemned diaphysectomy. Infection in th early stage was mild, and only dangerous becaus it was in an enclosed space and the blood-vesse were sinusoids through which pus easily passe into the circulation. Therefore the drainage oper tion should lay open only the area infected. Th usual operation produced an extensive wound wit painful dressings and protracted healing, leavin a wide scar adherent to bone and always liable t break down. To avoid this Mr. Ogilvie operate through a flap so that the skin scar did not overl the bone scar; he removed compact bone for th whole extent of pus formation and at least one-thir of the circumference. He left the medullary cavit alone, save for removing loose portions, and inserte a series of Carrel tubes without packing. The sk was then closed with interrupted silkworm sutur about an inch apart. This method had all th advantages of the open and the closed operatio He did not believe in radical secondary operation which only produced temporary relief. Operatio was only justified for abscess or sequestrum. H preferred to insert a silver wire down to the bon keeping it in place with strapping. The patient cou remove this daily. There was very little discharg and it stopped the tension in the deeper parts an abolished the intermittent bouts of fever. Transfusio was no use in acute sepsis.

Mr. N. DUNN described a case of osteomyelitis the spine, and Mr. ALAN PERRY described his expe ence at the London Hospital, where 75 per cent. cases gave a positive blood culture. He regarded th cases as pyæmic from the beginning rather than localised foci. Diaphyseal excision had been failure in his hands, yielding no regeneration in mo cases.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

A QUARTERLY meeting of this Association w held at the City Mental Hospital, Fishponds, Brist on Feb. 16th, Dr. HAMILTON MARR, the Presider being in the chair. A paper dealing with son points in the

Histology of the Globus Pallidus.

was read by Dr. E. BARTON WHITE. He said that amo the changes in the globus pallidus in various diseas several authors referred to striking changes in t walls of the blood-vessels of that body, manifest as a deposit of an amorphous material in their out walls, often sufficient in amount to obliterate t muscular and elastic fibres. It looked like calcific tion. Half the hundred cases examined by West Hurst at the National Hospital, Queen-square, show this change in the vessels, sharply limited to t anterior half of the globus pallidus. The ages of t patients ranged from 20 to 81. Hurst found that t material was not calcium, but a large portion of

was easily stainable iron. The material was also found lying free in the corpus striatum. Hurst considered that the deposit did not represent a senile change, and that it was not related to arterio-sclerosis, and in some of the cases he could find no pathological change in the nerve-cells of that nucleus. These deposits seemed to show, in Hurst's view, a proclivity of the globus pallidus to degenerate in the second half of life. Dr. G. Hadfield had shown that acute bilateral necrosis might affect the part of the globus pallidus in which the vascular change was found, and that a rich deposit of iron salts was present in the walls of the vessels of the pallidus in half the persons examined who had no chronic nervous disease, their ages being over 30. Dr. White's own figures corresponded with these. He submitted, as his conclusion, that the deposition demonstrated was as frequent in all forms of mental disorder as in chronic neurological cases and as in normal brains, and that, therefore, it could not be regarded as pathognomonic of any particular nervous disease, as some had previously contended.

Dr. GEOFFREY HADFIELD said the deposit spoken of was not a minute microscopical quantity, but could be easily made out with the aid of a hand lens. Many had concluded that the change in the vessels was pathological and that it caused, or largely contributed to, neurological signs and symptoms; it had, for instance, been put forward as a cause of post-encephalitic Parkinsonism, also as playing a large part in the causation of paralysis agitans. The change must be related to the fact that the globus pallidus was very rich in iron salts, as could be readily seen by putting a slice of brain into ferrocyanide of potash and hydrochloric acid, when it rapidly became a deep blue. An investigation led him to the conclusion that the iron which appeared in the vessel wall came from the nucleus itself—i.e., it was intrinsic iron—and he also considered that it was derived from a precursor in the nucleus which did not stain. The site of the deposit in the nucleus strongly suggested that the process was actually a degenerative one. It was, he said, tempting to think that perhaps the globus pallidus was a vestigial structure, which was undergoing evolutionary atrophy. There seemed to be no specific association with diseases. It was possible that this deposition of iron might predispose to disease; it certainly would alter the permeability of the vessels. The condition always seemed to be present in children, but in old people it was frequently found.

Prof. EDWARD FAWCETT said he was unable to throw any light on the subject of this paper. He agreed that the globus pallidus was one of the oldest parts of the encephalon. Dr. Hadfield's suggestion that it was a degenerative process which resulted in these depositions seemed fairly sound.

Dr. J. R. LORD spoke of the importance to psychiatrists of the basal ganglions as probably the seat of the central nervous mechanism of the emotions. Dr. John Brander at Bexley had investigated the presence in the brain of iron in cases of general paralysis, and had discovered that it was present in great quantities. He understood, however, that Dr. White had not arrived at the same conclusion. The presence of the iron in the globus pallidus, he thought, might indicate a regression of function, and that indeed the structure was a dying one. The extent of regression would vary in individuals.

Dr. G. E. PEACHELL asked whether Dr. White had investigated the brain of a patient who died of pernicious anæmia, and, if so, whether iron was found in that case. Also whether there was any analogy between the reaction which was found in the globus and the staining and pigmentation found in the brain after hæmorrhage.

Dr. WHITE, in reply, said that in one case of four having of general paralysis there was certainly no iron deposited.

Dr. HADFIELD, in reply, said he had not examined any cases of pernicious anæmia, but in that disease the pigment was taken out of the blood by a phagocyte. In the cases which had been examined there was no reason to suppose there was any excess of iron in the circulating blood. Neither was there excess of iron in the pathological series as opposed to the normal. He believed the deposition took place apart from any phagocytic cell action. And he thought hæmorrhage could be eliminated as a cause of the pigmentation or the change in the globus pallidus, as in the majority of these cases there was no sign of a pathological lesion.

Dr. CAREY COOMBS read a paper on the

Mental State in Cardiac Disease.

He said he had reviewed about 2000 cases of cardiac disease, and from them he had drawn certain inferences as to the connexion between such disease and mental disorder. His ideas he put in the form of answers to the following three questions: (1) Is there evidence that mental disorder causes cardiac disease? (2) Do the circulatory disturbances arising from cardiac disease often upset the mental functions? (3) How far are both cardiac disease and mental disorder, when they occur together, due to a common cause? In the war mental disturbance was often the chief factor in causing functional tachycardia; and mental stress and worry were appreciable factors in producing high arterial tension. He did not believe there was any form of heart disease which arose out of mental disorder. With regard to whether cardiac disease could be directly responsible for mental disorder, he had been struck by the absence of unimpeachable evidence in support of such a view. Still, severe cardiac disease was so terrible to contemplate that it might well upset the mental equilibrium of the person concerned, and also the deficiency in the cerebral circulation might result in mental trouble. It was rare to find insanity as a sequel of rheumatic heart disease. The incidence of insanity in uncomplicated heart disease was not higher than that of insanity in the general population. There were some conditions in which mental and cardiac symptoms appeared together, and might be ascribed to a common cause. In persons with senile heart disease, for example, the failure of the heart to supply blood adequately to the periphery was only one of many straws whose combined effect was to break the camel's back.

The PRESIDENT thought there would be general agreement that heart disease per se seldom caused mental disorder; and that when mental disorder followed heart disease it could usually be ascribed not to heart conditions but to the circumstances which brought about the diseased state—i.e., the autotoxic or microbic effect on the blood. With regard to cardiac conditions affecting the mind, it was usually the mental condition which caused the functional aberration; that was certainly so in many of the cases of shell-shock during the war; the cardiac condition usually came on after mental exhaustion.

Dr. LORD agreed with the President's remarks. The action of the heart was very much involved in the psychoneuroses and the neuroses. Insanity was so closely associated with the toxæmias that it was difficult, in a given case of acute insanity, to decide whether the cardiac condition was due to the mental state or to the accompanying toxæmia.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

AT a meeting of this Society held on Feb. 24th, with Colonel L. W. HARRISON in the chair, two papers were read on the

Treatment of Gonorrhœa in Pregnancy and in the Puerperium.

Dr. MARGARET RORKE dealt with *antenatal treatment*. She said it was now a matter of course for every upper middle-class woman in London to visit her doctor, not once but many times, for examination and advice

during pregnancy, whilst free antenatal clinics were now popular with the wife of the wage-earner, who took it for granted that she should undergo careful examination during this period. The change in public opinion during the last 10 or 12 years was astonishing. This being so, it was natural that as time went on the standard examination of the expectant mother should be more exacting. In most of the modern antenatal clinics almost any discharge occurring in pregnancy was investigated at once by the venereal diseases department, but there were five or six types of discharge commonly seen in addition to true gonorrhœa. Of these a discharge attributable to *Bacillus coli* infection was the commonest, and possibly it was more dangerous in its end-results than gonorrhœa itself. No patient, said Dr. Rorke, required more careful handling than the pregnant woman with gonorrhœal infection. If she was unmarried and deserted, a sense of utter helplessness overcame her; if she was married and realised that she was the victim of her husband's infidelity she suffered from wounded pride and bitter resentment. A correct understanding of the woman's psychology was very important to effective treatment. The first step was to have one, and if necessary more than one, Wassermann test carried out to ensure that she had not got syphilis as well as gonorrhœa. In all acute cases the patient ought to be immobilised by rest in bed, and the need for complete evacuation of the bowels, daily or twice daily during pregnancy, and of strict cleanliness, including the daily bath or wash down, should be impressed upon her. After instancing the various methods of treating the condition, Dr. Rorke referred to the value of diathermy where there was persistent infection of the urethra; it was useful to clear up the urethra in a patient awaiting delivery. The conditions to be aimed at were that there should be no ophthalmia neonatorum in the child, that the mother's pelvis in the puerperium should be in as good condition as that of a non-infected mother who had had the same type of delivery; and that complete cure of the infection should be brought about by continued treatment and supervision.

Prof. LOUISE MCILROY gave an outline of the working of the system of coöperation between the obstetrical unit and the venereal diseases department at the Royal Free Hospital. During labour vaginal examinations and operative interference were to be avoided as much as possible. Lacerations of the vaginal walls and cervix were the commonest cause of puerperal sepsis. During the third stage of labour the uterus should not be massaged unless hæmorrhage occurred, as sepsis might extend upwards from the membranes in contact with the vaginal secretion. Pyrexia in the puerperium occurred more often in gonorrhœal than in non-infected cases. Acute sepsis did not occur unless pyogenic organisms followed in the track of the gonococci. In the treatment of septic conditions free drainage of the uterus was essential and exploration of the cavity was only to be carried out if retention of portions of the placenta was suspected. Intra-uterine douching should not be permitted and patients should be kept in the open air as much as possible. Antistreptococcal serum was beneficial and, where extension of sepsis had taken place, intramuscular injections of quinine had value. She concluded by showing some tables of 322 cases treated at the Royal Free Hospital and gave full details of the deliveries and the puerperium. There was spontaneous labour with normal puerperium in 197 cases, and in the whole series there was not a single maternal death. It was interesting to note what happened to 34 infants whose mothers had combined infection of syphilis and gonorrhœa. Of these children 24 were satisfactory after spontaneous deliveries, 5 had ophthalmia neonatorum, 1 was stillborn, 2 were macerated, and 2 died shortly after birth.

Dr. EDITH HALL quoted cases showing the risk of very severe sepsis as the result of manipulation in the presence of gonorrhœa. She doubted whether it was justifiable in that condition to consider induction or Cæsarean section.—Dr. DOROTHY LOGAN emphasised the necessity of leaving off treatment very gradually as a safeguard against relapses.—Dr. FOWLER WA commented upon the rarity of interference in obstet practice 20 years ago, and advocated minimal int ference in childbirth where there was gonococc infection.—Prof. F. J. BROWNE said that gonorrh in pregnancy was rather difficult to define. Were cases which had a discharge in pregnancy to regarded as gonorrhœa? If not, a good many cas of true gonorrhœa would be missed. But if all cas with a discharge were treated on antivenereal lin many patients would come to the venereal departme who had not gonorrhœa at all. He did not like t idea of separating venereal from ordinary patients.

Dr. RORKE, in reply, said that she would defi gonorrhœa in pregnancy as a discharge, showing t gonococcus, either from the urethra or the cervix, a she would consider a persistent discharge in pregnanc not yielding easily to treatment, as probably gon coccal with secondary infection.

Prof. MCILROY said she could not agree wi Prof. Browne that these patients should be nursed common wards. The people in attendance had to considered. She had known a nurse acquire syphi because she was not aware that the patient, who w not in the venereal ward, was infected, and nobody h taken the trouble to tell her. Another objection bringing these patients into the common ward w that a large number of them were unmarried wome and some were of the prostitute class, and it was n possible to mix them up with decent married wom occupying ordinary maternity beds. She agre however, that venereal wards should not be labell as such.

Reviews and Notices of Books

X RAY PHOTOGRAPHY.

Kontrast und Schärfe im Röntgenbilde. By J. med. WILLEM BRONKHORST, Senior Physici Berg en Bosch Sanatorium, Apeldoorn, Holla Done into German by Dr. HEINZ LOSS Schatzalp-Davos. Leipzig: Georg Thieme. 19 Pp. 104. M.16.50.

THE quality of a radiogram is determined by t degree of contrast between its several shadows a by the sharpness of their edges. These two fact are influenced by several variables. Thus contr depends on: (1) intensity of the X radiatio (2) penetrating power of the rays; (3) thickness the object and of the media surrounding it; presence or absence of intensifying screens; scattered radiation; (6) chemical composition of film emulsion; (7) nature of the developer; temperature of the developer; (9) time of devel ment. Sharpness in its turn depends on: (10) s and nature of the focal spot in the X ray tu and (11) relative distances of the focus and object from the film. Although the photograp factors (6), (7), (8), and (9) have of late been elimina through standardisation of dark-room techniq seven variables remain, each of which has a bear on either the contrast or the definition in the X negative.

Dr. Bronkhorst may be congratulated on trouble he has taken to separate the effects of th seven factors from one another, thereby unravell a nasty tangle and sorting out the strings wh govern the making of a negative for any radiolog who cares to learn how to pull correctly. The fi part of the book deals with contrast. The aut used a set of aluminium steps, increasing in thickn from 0·5–12 mm., to represent the object which w placed between two layers of water varying in thi ness from 2–6 cm. This represented the surround tissue. By subjecting this arrangement to X r of four different compositions (55, 66, 77, 88 k and by working with and without intensify screens and a Potter Bucky diaphragm, he alt

n turn, every one of the first five factors mentioned. The results are recorded in a set of curves arranged o permit of comparison and discussed in the text.

Some of the most important of the many interesting esults which Dr. Bronkhorst found have been known rom empirical experience, but are here traced to their rigins. Thus he finds that radiograms are rarely ense enough—i.e., that intensity of radiation or time f exposure should be increased—and that viewing oxes should be much more brightly illuminated. urthermore, he finds that where scattered rays are ot removed soft rays should be employed, and hat intensifying screens, apart from reducing the ngth of exposure, add greatly to the contrast in hese circumstances. He also finds, however, that he elimination of scattered rays by a Potter Bucky iaphragm more than doubles the contrast, that this pplies to both thick and thin parts of the body, that nder such conditions hard rays are preferable to oft, and that though intensifying screens do not ffect contrasts when scattered rays are absent, they re of great importance in reducing times of exposure.

In the second part of the book the author deals ith definition and explains the cause and effect n it of what astronomers call penumbra. He draws ttention to the loss of detail caused through small bjects being so far from the film that the cone of bsolute shadow is at an end before the rays reach he film. It might perhaps have been better to express he effect of distances and size of focal spot in terms f definition, rather than of blurring, since, as he oints out, the former is merely the reciprocal of he latter; the more so as in discussing the effect f depth he refers to definition and not blurring. t the end of the book is a discussion of methods of easuring, not only the size, but also the shape and ature of focal spots; and here the results are very urprising and thought-provoking.

The book is a valuable contribution to a difficult ubject and is particularly commendable for the implicity of the apparatus used, the logical nature f the deductions, and the clearness of presentation he translation from Dutch into German has been ell done, with only an occasional mannerism. The rinting and illustrating leave nothing to be desired.

THE EXPECTANT MOTHER.

Advice to the Expectant Mother on the Care of Her Health. Second edition. By F. J. BROWNE, M.D., D.Sc., F.R.C.S. Eng., Professor of Obstetric Medicine in the University of London. Edinburgh: E. and S. Livingstone. 1928. Pp. 48. 6*d*.

IT is no matter for surprise that a second edition of his little book should be called for within a few months of the first. The author has succeeded n giving, in 38 pages, advice covering every mportant point on the care of the expectant mother, he preparation for confinement, and hints on breast-eeding and care of the baby. The book has been horoughly revised and some new matter added, hiefly in the last chapter, on the general care and lothing of the baby. Perhaps, in a future edition, he author might include a chapter on the care of the nother during the puerperium. The book is presumably vritten for middle-class mothers—e.g., the novels of Sir Walter Scott are recommended as a cure for leeplessness—but the explanations and directions re so simple and practical that almost any clinic nother would understand them. The teaching is on ommon-sense lines, and is that given in most up-to-late welfare centres. The only statement in the book o which exception might fairly be taken is that ailure to thrive in a breast-fed baby is never due o poor milk. Such cases may be rare, but they do ndoubtedly occur. Analysis of the milk shows a lefinite and sometimes marked deficiency in fat, vhich amply accounts for the baby's failure to gain veight. Apart from this small point, however, we have othing but praise for the book, which deserves a wide irculation, and would be cheap at double the price.

THE NATURAL HISTORY OF A SAVANT.

By Prof. CHARLES RICHET, Membre de l'Institut. Translated from the French by Sir OLIVER LODGE. London: J. M. Dent and Sons, Ltd. Pp. 155. 5*s*.

IN his deft dissection of the character of the savant, Prof. Richet often reminds us of his great countryman, Voltaire, in his most playful mood. It is true that the description of a savant as given by Prof. Richet belongs more to the men of his own country than to those of ours, and it is characteristic of the French intellect that a French savant should be able to describe his class with such facility and charm. His definition is rigorous, for according to him a savant is one whose sole aim is the search for truth to the exclusion of everything else, even to the exclusion of the practical results of his labours for the benefit of mankind. Subjected to this test, Newton and Darwin would be accorded niches in the professor's temple of fame, but the position would be denied perhaps to Kelvin, and Bacon's conception of gathering the fruits of science for the use of mankind might possibly exclude him from the temple of the elect. One of the most entertaining chapters is that which analyses the character of savants under a series of assumed names. Prof. Richet brings his luminous analysis to a close with two eminently sound propositions—viz., that "the welfare of mankind depends upon science," and "the progress of science depends upon savants"; carrying with them the necessary deduction that the savant must be cared for.

The translation of this delightful little book has been ably performed by Sir Oliver Lodge, who has entered thoroughly into the spirit of delicate irony which pervades it.

PRACTICAL PHYSICS FOR MEDICAL STUDENTS.

By MARY D. WALLER, B.Sc., Lecturer in Physics, London (R.F.H.) School of Medicine for Women. London: H. K. Lewis and Co., Ltd. 1927. Pp. 95. 6*s*.

IN Miss Waller's book is to be found the outline of an elementary course in practical physics. It is, in fact, the course followed by students at the London School of Medicine for Women who are preparing for the London or Conjoint qualifications. As the author states, this work is done in conjunction with demonstrations which, no doubt, amplify the written word. Sometimes the aim of the experiment seems hardly defined enough; as, for instance, in the experiment on the path of a projectile, the student is advised to tabulate certain quantities though it is not made clear for what purpose. We miss diagrams, especially in the optical section; many of the difficulties of the students would disappear if diagrams were insisted upon in practice as well as in theory.

It is a pleasure to recognise the origin of some of Miss Waller's methods of teaching. Those who have had the privilege of submitting at the hands of the late Prof. A. Waller to the psychogalvanic reflex test will be glad to see it included in exercises upon the Wheatstone Bridge. The note on the "Self" method of producing and determining the direction of a current through a galvanometer is, we venture to think, traceable to the same source. We could wish that there were even more of such links with a great physiologist.

THORACOSCOPY.

Atlas Thoracoscopicon. By Dr. FELIX COVA, of the Vittorio Emmanueli III. Sanatorium. Milan: Sperling and Kupfer. 1928. With 50 plates. 37*s*. 6*d*.

Dr. Felix Cova has produced a very fine and comprehensive atlas illustrating the various pathological conditions which may be seen in the pleural cavity by means of the thoracoscope. It is evident that in the Vittorio Emmanueli III. Sanatorium of the City of Milan, the thoracoscope is used extensively, with

the result that it has been possible to reproduce most of the typical conditions that are to be found within the pleural membranes (with certain exceptions such as actinomycosis, hydatids, and primary tumours). Following on three anatomical pictures there are 38 plates illustrating the various inflammatory conditions varying from hyperæmia, through the dry and wet pleurisies to purulent effusions and fistulæ; plates of tuberculosis and syphilis, secondary malignant deposits, fracture of a rib, diaphragmatic hernia, subpleural emphysema, and adhesions are included. These are followed by nine illustrations depicting Jacobæus's operation. The coloured illustrations give a faithful picture which shows clearly the characteristics of the individual lesions. The descriptions, and the author's preface and that by Jacobæus are in three languages. Whilst the German translation of the original Italian text is excellent, the English translation leaves much to be desired.

As the author points out, this is the first atlas of its kind which has been produced, and should be valuable to all who are undertaking thoracoscopy and who are interested in visualising the appearances due to pathological lesions in the pleural cavity. The reproductions are so clear that, given experience in the technique, the recognition of the various lesions in vivo should be greatly simplified.

THE DIARY OF A MEDICAL STUDENT DURING THE MID-VICTORIAN PERIOD, 1860–1864.

By SHEPHARD T. TAYLOR, M.B. Norwich: Jarrold and Sons, Limited. 1928. Pp. 201. 3s. 6d.

Mr. Shephard Taylor, the son of a Norfolk squire, had a successful student's career, especially distinguishing himself in botany. He was for many years on the staff of the Norfolk and Norwich Hospital and is now approaching the age of 90. His diary is that of a close and shrewd observer of matters both medical and otherwise. It affords a valuable retrospect of manners, modes, and men in medicine and surgery in the immediate pre-Listerian period, together with an amusing and critical survey of London viewed through the eyes of a provincial medical student in mid-Victorian times. His discursive and chatty diary is thoroughly interesting, dealing with the serious, the intimate, and the petty with equal humour and discrimination. The diary was kept when the author was a medical student at King's College Hospital during the years 1860–64, and is more or less a record of his own career as a student, with pithy and apt comments on medical and surgical happenings—examinations, operations, and the clinical features of medical and surgical cases. These notes are interspersed with lighter matter, outside medical interest, but maintaining the personal note. There were important men at King's College Hospital in the early 'sixties, among the staff being the professors of surgery, Sir William Fergusson and Sir William Bowman, the professor of physiology, Lionel S. Beale, the professor of medicine, Sir George Johnson, and the professor of materia medica, Sir Alfred Baring Garrod. The medical student, who is open eyed, is often a sound critic of his teachers, and when not prejudiced his opinions are sometimes worth while if they were made in statu pupillari, and are not the outcome of his later reflections, and Dr. Taylor's were made on the spot. He admired greatly Sir Alfred Garrod, but condemned the then almost routine treatment of typhus fever, at the time very rife in the neighbourhood of King's College Hospital, with large doses of alcohol; this treatment Garrod followed and in the opinion of young Taylor it was responsible for the mortality-rate which prevailed. The student-critic had the courage of his views, for he wrote a paper condemning the use of alcohol in typhus fever which was ranked "A 1" by Dr. John Harley for the King's College Medical Society's Prize.

Among public events noted by the diarist, he witnessed, in the intervals of a midwifery case in a street off the Strand, the public entrance of the late Queen Alexandra into London; he saw the great Tooley-street fire, and several public executions, including the hanging of five Malay pirates at the Old Bailey on Feb. 21st, 1864. Dr. Taylor has done well to publish the commentaries of his youth; such documents make for a real comprehension of medical history, scientific and social.

JOURNALS.

LE SANG, Vol. I.—This journal[1] has now completed the first year of its life, and the six numbers so far published have fully justified its existence. Much useful material has been collected in the first volume. The subject of the blood groups, which for some reason has hitherto failed to attract much attention in France, is competently dealt with by M. Lamy and A. Mendes Correa, the former reviewing the general situation in regard to the groups and the latter the anthropological implications as they now stand; given this ample exposition of the subject in their own language it may be hoped that French workers will now turn their serious attention to the numerous relevant problems still to be solved. Among other valuable papers J. Jolly reports the results of investigations on the action of radiant energy upon the lymphoid system, and J. Barcroft describes the results of his work on the relationship of the mass of the spleen to the volume of circulating blood; this has already been reported in our own columns. A biography of that doyen of hæmatology, Prof. Georges Hayem, constitutes an interesting and very welcome feature of the first number. On the Comité Etranger it is pleasing to observe the names of "J. Barcroft (Cambridge)" and "Sir Wright (Londres)."

JOURNAL OF INDUSTRIAL HYGIENE.—February: An excellent article is contributed by S. Meyer from Dusseldorf, based on a long series of examinations of blood from workers exposed in factories to such toxic substances as benzol, toluol, xylol, naphthalene, aromatic nitro-compounds, arsine, thallium, and hydrocyanic acid. The material was obtained by Dr. Teleky in the course of his work as medical inspector of factories. Regardless of which poison was acting, invariably the lymphocytes showed an increase, and the neutrophils a decrease. A similar reaction is said to occur in diseases of the endocrine-sympathetic nervous system. The author, therefore, suggests that chemical poisons named act upon the endocrine glands and disturb their functions, and sees here an explanation of why aplastic anæmia is originated by such poisons. A further article is the fifth in a series dealing with metal fume fever, and describes the results of exposing rabbits, rats, and cats to the inhalation of zinc and magnesium oxide fumes. The authors, K. R. Drinker and P. Drinker, induce deep breathing by adding 10 per cent. CO_2 to the fume-laden atmospheres. There is a full account of the experimental work. Falls in body temperature occurred, varying with the duration of exposure, in contrast to the rises which occur in man. Zinc oxide fumes caused a heavy outpouring of polymorpho-nuclear leucocytes, indicative of an irritative process which may go on to broncho-pneumonia. Zinc, which is not in itself toxic, appears to be excreted by the kidneys and liver; the pancreas also may be concerned.

---

KING GEORGE'S HOSPITAL, BECONTREE.—Under this name a new voluntary general hospital of between 300 and 400 beds is to be created on the new Becontree Estate of the London County Council in Essex. The scheme has been approved by King Edward's Fund which, by reason of the recent extension of its radius, now includes this district. The existing buildings of the Ilford Emergency Hospital (42 beds) will be used as the nucleus of the new buildings which will be erected in contiguity to it. A board of management constituted from each of the districts served will administer the institution, to which the King and Queen have promised to contribute.

THE LANCET.

LONDON: SATURDAY, MARCH 10, 1928.

INDUSTRIAL RHEUMATISM.

THAT a scheme is on foot for the establishment in London of a clinic for the employment of physical methods of treatment with special reference to rheumatic conditions is known to the medical profession and the public. This proposal of the British Red Cross Society to found a centre accessible for certain classes of sufferers from industrial rheumatism is the first expression of a movement which has already well-known continental examples, and we are glad to learn that substantial pecuniary support has been received already. Of the sum of £40,000 which was considered to be necessary to meet the cost of founding the first clinic over one-third had been received some weeks ago, and when the figures are published it will be appreciated that an immediate start can be made in what should be a most valuable public effort. At the meeting last week of the Council of Industrial Medicine, in connexion with the Federation of Medical and Allied Services, workers of experience in that particular regard pointed out the directions in which industrial rheumatism would be amenable to organised treatment, while Dr. M. B. RAY dwelt in more detail upon the aims of the British Red Cross Society. They were voicing views held by all who have any knowledge of the misery and inefficiency which result for a large section of our population from the varied group of symptoms termed, collectively, industrial rheumatism.

The scheme of the British Red Cross Society has matured in the decision to start a clinic for the treatment of rheumatism in adult sufferers, especially industrial workers, in an accessible place in London, and an option has been secured on a suitable building in Marylebone. The first funds collected will be used for the adaptation and equipment of the premises, and the future of the project can hardly be in doubt seeing the powerful endorsement which it received in the *Times* at the beginning of this year in a letter signed by Sir ARTHUR STANLEY, chairman of the Red Cross Joint Committee, and a group of distinguished men, physicians and physiologists, officials and public workers. Further, the scheme has the support of the representatives of industrial and friendly societies and of many other health organisations, whose managers are all alive to the serious inroads made by rheumatism upon the well-being and wage-earning capacity of their constituencies. Compared with the urgency of the evil the sum of money required to start a practical organisation for its relief is small, and the proportion of that sum already promised in donations makes it seem likely on every count that the total which has been asked for publicly will be forthcoming promptly. And as the first step in their large policy proves successful, we may be sure that the British Red Cross, and those associated with them in the scheme, will be pressed to pursue their activities, for the extent of the need will be more widely recognised. A memorandum from a subcommittee of the British Committee on Rheumatism, itself a committee of the International Society of Medical Hydrology, has been issued giving a summary of what is necessary in a clinic intended primarily for the benefit of insured rheumatic persons, who constitute such a heavy burden upon medical service. More than 370,000 individuals under the National Health Insurance Act alone seek relief annually from their panel for rheumatic diseases, and as London has an insured population of nearly 2½ millions the number of rheumatic persons requiring treatment in the metropolis is huge. It is easy to see that those who are now putting out a working plan for treatment have to think largely, and must also define clearly their initial design. For the purpose of the clinic which it is now proposed to start such varieties of rheumatism as rheumatic fever, acute rheumatoid arthritis, and acute inflammation of fibrous tissues are not under consideration, for it is an ambulatorium rather than a hospital which is in contemplation. The patients who are suitable for treatment must be able to walk, or at any rate be in a condition which enables them to be brought to the centre, where the subacute forms of rheumatism, arthritic joints, lumbago, sciatica, and fibrositis will be treated, as well as the mechanical impediments which follow acute or subacute attacks, and all disabilities due to accident or injury which have assumed a rheumatic form. It will be the special object of the first centre, which is situated near Great Portland-street railway station, alike to prevent the development of these mechanical disabilities and to relieve the results of the exudations and adhesions which damage so sadly the working capacity of their victims. For this purpose the clinic will have at its disposal all the necessary equipment for the application of heat and cold, in water or vapour, for all methods of manipulation, and for the prescribing of exercises, alone or in combination with other methods. The clinic will be able to apply radiation, as heat, light, and invisible rays, and electricity in constant, interrupted, or high-frequency currents; and these physical methods will be accompanied, where necessary, with the indicated forms of medical and surgical treatment. Speaking generally, the patient will have at each visit two or more of the methods applied in succession, and this combined treatment will be continued in accordance with the progress made; and while experience suggests that slight cases may require brief treatment the value of periodical physical treatment is recognised—indeed, it can be demonstrated from the records in the possession of many medical men familiar with spa therapeutics.

We are behindhand in this country in our realisation of the toll which is paid through a large class of afflicted workers, and also in our unfamiliarity with the value of the systematic treatment of many rheumatic conditions. Over a year ago Dr. RAY, writing in our columns[1] as honorary secretary of the British Committee on Rheumatism, described the existing situation in many continental States, and demonstrated how much we lack both in care and prevision. But lately there have been signs of the intention to do better, and we welcome the fact that a conference will be held in May next at Bath under the presidency of Sir GEORGE NEWMAN, at which rheumatic diseases will be considered under their social and medical aspects by leading scientific authorities. Such a conference will prove the need for clinics like that which is now about to be started in London. We have experience of good results from systematic treatment at our spas, where scientific hydrology combined with physical procedure is systematically employed, and the place of British spas will be made clearer by the relegation of cases from the new clinic to certain centres for apt treatment. Further, while the medical profession and, through them, the public can be familiarised

[1] THE LANCET, 1926, ii., 935.

with the scientific use and conditions of physical methods, material will be available for the investigation of the influence of occupations upon the population, and facilities will be furnished for the concurrent investigation of incipient subacute and chronic diseases. We have some distance to make up, but the signs of an earnest start are promising.

ABSCESS OF THE BRAIN.

CEREBRAL abscess must always be regarded as imminently dangerous to life, for it is almost invariably fatal if untreated. Yet there is no disease of the brain which can be approached with greater confidence of success, and as long ago as 1893 MACEWEN was able to report 25 cases, in 19 of which operation was performed, with 18 recoveries. The reasons for a hopeful outlook are not far to seek. Though occasionally due to infection through a compound fracture of the skull, or to transmission of bacteria from infective foci in the lungs or pleural cavities, cerebral abscesses are generally caused by infection spreading from the frontal sinus or middle ear. In those of otogenic origin, which far outnumber all the other varieties, extension of disease to the brain is usually heralded by symptoms referable to the ear. The infection passes in certain clearly defined directions and the abscess is to be found in the white matter of the adjacent temporal lobe or cerebellum. It tends to become "encapsulated" and its ill-effects are produced not by destruction of the vital parts of the brain, but by a local and general rise of intracranial pressure. These facts mean that to discover its presence and situation should be relatively easy compared, let us say, with the diagnosis of intracranial tumours. But in actual practice the warning signs may be slight and the rapid rise of intracranial pressure, so characteristic of abscess formation, may speedily induce a drowsiness which interferes with examination of the patient and thus militates against accurate localisation. It is for this reason that complete neurological investigation is urgently required in all cases of chronic otitis media in which headache makes its appearance, and in all cases of acute mastoiditis in which the temperature fails to settle after operation. The localising signs that should be sought for have been admirably described by Dr. C. P. SYMONDS [1] in a recent address to otologists. For cerebellar abscess, which is usually situated in one lateral lobe, Dr. SYMONDS regards incoördination of the upper limb on the corresponding side, and nystagmus, or lack of conjugate movement of the eyes towards the side of the lesion, as the most valuable diagnostic signs. For temporal abscess weakness of the face, signs of involvement of the pyramidal tract, and defects of the visual fields, on the side opposite to the lesion are of cardinal importance. When the abscess is in the left temporal lobe (in a right-handed person) an additional sign of great value is dysphasia, often limited to a difficulty in naming objects and not necessarily apparent in the patient's ordinary conversation.

In the Hunterian lecture which we publish on another page Mr. MILES ATKINSON lays stress on the importance of certain early general signs of intracranial suppuration. He considers that in cases of otitis media the onset of cerebral abscess is characterised by "an initial feeling of chilliness, possibly even a rigor, headache, some rise of temperature, and nausea or vomiting," and he urges that diagnosis should, if possible, be made from the detection of these changes before the onset of the localising signs described above. Mr. ATKINSON does well to call attention in this way to the early stage of abscess formation and he is probably correct in believing that the mastoid process should be explored, or reopened, at this stage; for the spread of infection to the brain can be limited, and development of cerebral abscess can often be prevented, by timely and adequate drainage of mastoid and extradural abscesses. It is doubtful, however, whether he is wise in recommending exploration of the brain before the appearance of the localising signs, as patients who show symptoms such as he describes recover sometimes without any surgical interference with the brain itself. Success in treatment depends on an understanding of intracranial pathology. The rise of pressure occasioned by the formation of a cerebral abscess is both sudden and progressive, and the brain has little opportunity of adapting itself to the new conditions prevailing within its rigid covering. The degree to which tension is raised is shown by the remarkably rapid onset of papillœdema, severe headache, drowsiness, and other signs of acute hydrocephalus, and by the appearances seen at operation. When an abscess is opened its walls are rapidly obliterated by the pressure of the surrounding brain, and it is notorious that an abscess which has been partially emptied is extremely hard to find again, either at operation or by subsequent passage of the exploring needle. Failure to empty the abscess completely allows pus to be trapped in the depths of its cavity so that recurrence may follow after a period of temporary improvement. No time is so favourable for drainage of an abscess as the moment when the pus is first discovered, and for these reasons it is inadvisable to treat the condition through a small opening in the skull, or by such measures as repeated aspiration and the insertion of small drainage-tubes which do not reach to the bottom of the abscess cavity. It seems more rational to make a wide opening in the skull and dura, the situation of the abscess having previously been mapped out by passage of a brain needle down to—but not through—the resistant wall of the abscess. When the abscess is opened a large drainage-tube should at once be passed down into the depths of the cavity, where it is left to be extruded by the brain during the development of the fungus cerebri that usually follows. The formation of fungus cerebri is to be desired, since it displaces the remains of the abscess cavity to the outside of the skull and thus allows rapid restoration of normal pressure within. It soon heals and subsequently gives no trouble.

Thirty-five years have passed since MACEWEN published his remarkably good results, and it is to be regretted that Mr. ATKINSON does not give us the results of more modern workers. In spite of advances in neurological diagnosis and surgical treatment, it would not be surprising to learn that no one has been able to improve on MACEWEN'S successes. Modern specialism has not been favourable to the treatment of cerebral abscess, inasmuch as it has produced three artificially restricted fields of endeavour—aural surgery, neurology, and neurological surgery—each of which tends to monopolise some branch of practice that is essential to successful management of the disease. Such specialisation inevitably leads to divided responsibility for the treatment of a condition which is pre-eminently one of emergency demanding the control of a single individual who is thoroughly familiar with all its aspects.

HEAT IN THE RELIEF OF PAIN.

THE medical profession owes an increasing debt of gratitude to the chemists and biochemists of the great manufacturing houses for their labours in making available so many lines of treatment in the handy form of tablet or ampoule. There is a danger, however, that this "treatment made easy" may lead us to forget the use of, and method of using, some of the older therapeutic measures which have stood the test of time. Blood-letting, cupping, and the rest were powerful weapons in the careful hands of the older physicians, and Dr. JOHN HARVEY KELLOGG has done a service by drawing attention in the *American Journal of Surgery* for December last to the value of heat for the relief of pain. He traces the therapeutic use of heat in this connexion from the lower animals, through children and the primitive people of all countries, to the present day. The exact mode of action is not fully understood. Heat may relieve local congestion by producing a collateral hyperæmia, it may break down a vascular stasis, and it is suggested that it causes an inhibition of the sensory nerves and so relieves pain by acting through the thermal nerves of the skin. This power of relieving pain seems to be a specific property of heat, common to heat waves of all lengths but most marked in the short infra-red rays, possibly on account of their greater penetrative power. To obtain the best results the heat must be intensive, or as "hot as the patient can bear," and to apply it, careful and continuous attention is required either from doctor or nurse. It is not just a prick with a hypodermic needle and away. Heat can be applied by compress, poultice, hot-water bag, hot stones, heated air or electricity in various forms, and may be given either dry or moist. The intensity of dose may be greatly strengthened by combining some method of cooling the skin surface, such as evaporation or the intermittent use of cool air. Treatment of this nature, like every form of therapy, requires a knowledge of when and how it should be employed, and it ought not to be left to a nurse or an attendant as being below the personal attention of the physician. Unfortunately this is often done because the physician is not skilled in the niceties of its use. Sir LAUDER BRUNTON, in his "Action of Medicines," published over 30 years ago, gave minute directions as to the proper making of a poultice and advised his readers to connect in their minds "the two p's: pain and poultice." Does poultice-making still find a place in the modern medical curriculum? It is doubtful. The apprentice system had much to commend it, and one of its virtues consisted in the handing down from generation to generation of a number of practical points in what might be called minor medicine and surgery, the knowledge of which made the distinction between the master and the apprentice. No one who has seen the relief which follows a good poultice in a case of abdominal colic, or who has obtained for his pneumonia patient a couple of hours' sleep with a well-timed mustard paste, will ever doubt the value of heat therapy. Besides, it reduces the drug bill and lessens that chance accident which every true physician dreads—the formation of a drug habit.

A MEDICAL CRUISE.—Every year the *Bruxelles Médical* organises a cruise for doctors, their families, and their friends. This year it will start at Bordeaux on July 29th and end at Marseilles on August 18th, the places to be visited including Vigo, Funchal, Santa Cruz de Ténériffe, Las Palmas, Casablanca, and Ajaccio. Information may be had from the Section de Voyages de *Bruxelles Médical*, 29, Boulevard Adolphe Max, Brussels.

Annotations.

"Ne quid nimis."

WELFARE OF THE BLIND.

THE yearly reports of the Advisory Committee on the Welfare of the Blind show a steady improvement in their condition since the passing of the Blind Persons Act of 1920, and the latest[1] of them states that 14,563 blind persons between the ages of 50 and 70 are in receipt of Government pensions—i.e., 84 per cent. of those within the eligible age. Schemes for promoting the welfare of the blind have been submitted by all the 146 local authorities concerned, and having been approved by the Minister of Health are now in operation. In all but 30 cases the arrangements made are working quite satisfactorily, the difficulties in the minority of cases being due partly to the want of an efficient voluntary organisation and partly to the difficulties of administration in rural areas with a widely scattered population. The expenditure incurred by local authorities in this connexion and the grants in aid from the Ministry of Health have both been steadily growing, the amounts under these headings for the financial year 1926–27 under the former head being £173,828 and under the latter £112,510. The bulk of this money was spent on workshops, home-workers, home-teaching, and books. The statistics given show that the Blind Persons Act has led to the discovery of a large number of blind who were hitherto unknown. Apparently the granting of free wireless licences to the blind in 1926 has led to the discovery of a considerable number who were unregistered. Another thing that comes out is a slight decrease in the number of the blind under the age of 21 in spite of a considerable increase in the later decades, a decrease which presumably indicates some degree of success in the measures in operation for the prevention of infantile blindness. Apropos of these statistics it is difficult to accept the figure 0·5 per cent. which purports to represent the total blindness existing under the age of 5 years, compared with what exists at all later ages. This figure appears to be quite inconsistent with the figures in another table showing the percentage of the total of blind persons who became blind at various ages. It is true that between 1919 and 1927 the percentage of those who became blind under the age of one year compared to the total number diminished somewhat, but in the latter year it was still 17·4. We made a similar criticism of the figures of the sixth report published in 1926[2] and suggested as an explanation that a considerable proportion of children under school age escape registration. It must be a very large proportion. Other figures show that although the total number of blind persons employed in remunerative work has increased between 1919 and 1927, the percentage in relation to the total number of the blind had decreased from 24·6 to 19·6. This is accounted for by the large number of blind persons over 50 added to the register. One of the favourite occupations is piano-tuning. "It would appear," says the report, "that the general remunerativeness of this occupation has attracted a number of persons who are not really suitable or competent, and in the interests of the qualified tuner we think it desirable that in future only those persons with the highest technical and personal qualifications should be encouraged to take up this occupation." We are glad to observe that an important section of the report is devoted to the difficult problem of partially blind children. The partially blind are outside the scope of the benefits conferred by the Blind Persons Act. It is estimated that there are some 7000 partially blind children in England and Wales, and at present there appears to be accommodation for only 1500 of them in special schools for myopes and the partially blind. Meantime there is considerable pressure put on the managers of blind schools to admit these children, for whom the

[1] H.M. Stationery Office. 1928. Pp. 33. 6*d*.
[2] THE LANCET, 1926, ii., 760.

regimen is not altogether suitable. The report rightly deplores the fact that so little has as yet been done to equip persons of this class for taking their place in the industrial life of the country. The suggestion is made that there is ample scope for voluntary enterprise to take up and develop what is really a new social service.

COLLOID CANCER OF THE STOMACH.

IN a thesis submitted to the Graduate School of Minnesota Dr. J. W. Stinson,[1] of the Mayo Foundation, states that the first statistical studies of gastric carcinoma were published in the *British and Foreign Medical Review* of 1857 by Brinton, who in a series of 135 cases found that 9·4 per cent. were of the colloid type. In a series of 2516 pathologically proved cases of carcinoma of the stomach examined at the Mayo Clinic from March 1st, 1913, to May 1st, 1925, colloid changes were found in 121, or about 5 per cent. Twenty-five were in women and 96 in men; the average age of the women was 50·5 years, and of the men 53·3 years, the general age being 52·7 years. The oldest patient was aged 79 and the youngest 31. As regards the symptoms, Dr. Stinson says that there was nothing to differentiate colloid carcinomata from other types of gastric cancer. The only certain method of distinction consisted in exploratory operation and microscopical examination of the tissue. The structure of colloid carcinoma is similar to that of ordinary adenocarcinoma of the stomach except that a large amount of mucus is present. In typical cases the whole wall of the stomach is almost completely changed by the presence of colloid material, so that the cut surface is clear and gelatinous and of a soft consistency. Colloid changes may be noted in the earliest stages of the carcinomatous process and are frequently found on microscopical examination when they are not visible to the naked eye, especially in cases with small ulceration in which the diagnosis lies between benign ulcer and carcinoma. In the present series 97 cases, or 80 per cent., were operable, and the growth was removed; 19 were inoperable and 5 were suitable for palliative measures. The percentage of cases still alive three and five years after operation is about the same as in the non-colloid types of carcinoma, but the incidence of late recurrence is greater in the colloid variety. The post-operative mortality-rate is about the same as in the non-colloid types, the post-operative life expectancy being less in young patients.

THE RED CROSS BLOOD TRANSFUSION SERVICE.

ONE day in 1921 the Camberwell division of the London Branch of the British Red Cross Society was asked for a blood donor for an emergency case. Four members immediately volunteered, and the secretary of the division, seeing that the work was eminently suitable for the Society, instituted a roster. One of those who responded to the appeal was a Rover Scout, who induced his colleagues to adopt blood transfusion as one of their forms of service. In 1925 the Red Cross headquarters took over the organisation, and appointed a committee consisting of representatives from the Society, the Rovers, and the Hospitals Association. In 1926 no fewer than 737 applications for donors were received, and on three occasions only had the request to be refused. The report of the Blood Transfusion Service for 1926 contains a very interesting account of its working. The office is open day and night; in fact, 198 of the calls during the year were urgent. Most donors are called up by telephone at their place of business, and for this reason 6 P.M. is the best time to make the appeal, as it obviates special leave. Until the post offices close, express messages are sent, and after that summonses are transmitted through hostels and private persons with telephone facilities. There is great need for more volunteers for this part of the work. Like most altruistic services, this one suffers much from popular ignorance. The belief that transfusion is dangerous and harmful to the donor is almost universal, and only many years of public education will eradicate it. The truth is, as medical men well know, that the operation is never dangerous and is often beneficial to the donor. The rules of the Society protect donors from being operated on by students and from any but the needle method of extraction. The lay press is generally very helpful in appealing for volunteers, but occasionally prints indiscreet paragraphs about "heroism," which lead to apprehension and a number of withdrawals. Further economies in the service could be effected by hospitals if they would take more care to eliminate the possibility of obtaining a relative before calling up the service, and would avoid as far as possible calling on universal donors (Group 4). The scheme has been financially self-supporting from the start. Two hospitals subscribe 10 guineas each a year, but the bulk of the revenue is derived from donations from private patients and the sale of tinfoil, £60 worth of which was collected in 1926. Although there is still urgent need for volunteers, the London service is well set upon its feet, but the provinces are not so well supplied, since, apart from a few local services there is no regular organisation at work. One great difficulty is the lack of facilities for grouping patients and donors, and even of surgeons competent to carry out transfusion without pain and inconvenience to the donor. No volunteer, however altruistic, will submit to a series of incisions which he knows are unnecessary. That a service of such value should be wasted on this account is a reproach which we hope the provincial hospital staffs will do their utmost to remove.

STANDARDISATION OF REMEDIES.

THE second annual report of the laboratories of the Pharmaceutical Society of Great Britain shows steady continuance and expansion of the invaluable work they perform for the public health. The two main purposes of this work are pharmacological research, especially into methods of assay, and the biological testing of manufacturers' products. Two events particularly marked 1927. At the beginning of March the new department for vitamin tests began to receive samples, and at the beginning of August the laboratory began to take its part in the administration of the new Therapeutic Substances Act, a duty which meant a great increase in the number of samples of pituitary extract submitted for examination. Alongside this work research has been carried out at Queen Charlotte's Hospital to relate the new system of dosage of this extract to clinical requirements. The Act enjoins that manufacturers shall state the strength of their preparation in units, but leaves them free to sell as many units as they like in each ampoule. The majority, following the United States Pharmacopœia, put up 10 units in 1 c.cm. The preliminary observations of the laboratory staff show that 10 units is a wasteful and occasionally dangerous dose, and that 5 units in 1 c.cm. is sufficient for general purposes. A suggestion that is to be further tested is that manufacturers should prepare doses of 2 units only, a quantity which appears to be safe at any stage of labour where there is no mechanical obstruction. In addition to this work, the staff have been examining the action on the parturient uterus of the various constituents of ergot, and have come to the conclusion that, as the action of histamine is powerful but evanescent, and as tyramine is inert the value of ergot lies in its specific alkaloid ergotamine or ergotoxin alone. The report goes on to say that since the water extract of the British Pharmacopœia contains none of this alkaloid, not one ounce of the thousands of gallons made since 1914 can have had any medicinal value.[1] An assay by the Broom and Clark method of several samples of ergot prepared

[1] Surgery, Gynecology, and Obstetrics, February, 1928.

[1] These investigations of uterine stimulants have been discussed in a leading article in THE LANCET (1927, ii., 560).

according to the U.S. Pharmacopœia showed that, whereas Spanish and Portuguese ergot yielded a fair proportion of active samples, 26 out of 27 samples of Russian or Polish ergot had no appreciable activity. This result has been confirmed by the U.S. Department of Agriculture. An investigation into the best method of preparing liquid extract of ergot showed that only the extracts of the U.S. and Dutch pharmacopœias retained specific activity. Among other assay work a standard has been fixed for squill, and results from the rat method of examining digitalis tinctures have been compared with the results obtained on patients; the comparison is nearly complete and is unexpectedly promising. In testing digitalis samples the Society ceased last year to follow the recommendation of the Geneva Conference, which urged that certificates should only be given for samples which did not differ from the international standard by more than 25 per cent. In view of the large number of samples which exceed the upper limit of potency, and the possibility that the next conference may revise this recommendation, a certificate is given for strong samples in an altered form, stating by how much the international standard is exceeded.

The other activities of the laboratory have a large range. Work on the œstrus-producing hormone has confirmed the principles of determination laid down recently by Trevan. Research into the metabolism of rats on a fat diet, especially into ketonuria, shows that the excretion of acetone bodies may be ten times in summer what it is in winter; that it can be inhibited by the injection of pituitary extract or adrenalin, and strikingly increased by insulin. The experimenters conclude that the amount of carbohydrate in the diet has only an indirect influence on ketonuria. The vitamin-testing department is now in full swing. Rats have been obtained from several first-class sources, and an attempt is being made to establish a stock colony of Wistar rats (a highly inbred strain) and feed them on a diet of known composition. An effort with Steenbock's diet broke down in the third generation, probably owing to a deficiency of accessory factors in the particular maize and lucerne used, and Sherman's has failed for the same reason. Nevertheless, success is essential if a serious advance is to be made in vitamin estimation. Ordinary rats may vary enormously in their requirements; six Wistar rats will give a degree of accuracy attainable only with 10 casually chosen animals. To obtain accurate results and keep the numbers within reasonable bounds it is necessary to secure the greatest uniformity. The tests for vitamin D are now fairly certain, and McCollum's "line" test has been verified by X ray photographs, but as yet no standard exists for vitamin A. Höjer's method of estimating vitamin C is being investigated. So far 43 samples have been tested for manufacturing firms by this department, which promises to maintain the high traditions of the Society.

THE PHYSICAL BASIS OF CONDUCT.

"I hope you have recovered from the snappishness from which you were suffering when I last saw you" was, we are told, a common morning greeting among the Erewhonians, and "if the person saluted is still snappish he says so at once and is condoled with accordingly." When Samuel Butler's book was first published in 1872 it was regarded as a piece of amusing satire, far removed from rational procedure. It seems not unlikely, however, that another 50 years will see us taking a very similar attitude to that of Mr. Nosnibor in these matters. Such at least was the conclusion to be drawn from Sir Farquhar Buzzard's discourse to the Royal Institution on March 2nd. He brought forward evidence, supplied by anatomist, physiologist, and pathologist, to show that every change in behaviour has its corresponding change in the central nervous system. Fatigue, heat, or a circulating toxin will so act on the nervous element that its granules are broken down, its shape altered, and its nucleus displaced. Already we are tolerant of the peevishness of convalescence, realising that it is the result of a direct physical cause for which the patient should not be held culpable. We know that the small boy, described by the lecturer, who displays for a week or so after an attack of influenza the primitive emotional reactions proper to a much younger child, will in a short time regain the inhibitions he had recently acquired and become once more the well-mannered person we have produced by careful tuition. Much bitter experience has taught us that punishment, care, and education avail nothing for the victim of encephalitis lethargica, who is, as Sir Farquhar Buzzard put it, hopelessly lacking in moral responsibility because the germ has made havoc among those cells and fibres which should exercise inhibition over childish behaviour. The physiologist, again, has shown that bad language belongs really to the group of "release phenomena" and probably means no more in the bargee or the overworked business man than in the patient going under an anæsthetic or the experimenter shut up in a chamber from which oxygen is being withdrawn. Nevertheless the teaching that sickness is crime and crime is disease has hardly begun to penetrate the public mind, and it is in paving the way for a very necessary change of public opinion that lectures like the discourse at the Royal Institution are so useful. When the intelligent layman realises that changes in behaviour are associated with alteration in structure he will be approaching the disorders of body and mind in a rational and enlightened manner, and he will see the law in its proper light, as an instrument for the public convenience rather than a mechanism for distributing abstract justice.

TREATMENT OF STREPTOCOCCAL INFECTIONS WITH ARSENICAL COMPOUNDS.

It will be remembered by those familiar with the literature that after Ehrlich introduced salvarsan for the treatment of spirochætal and protozoal infections the drug was used by a great many uncritical observers for the treatment of all types of infection, in much the same way as insulin has been used for conditions other than diabetes. After a time these empirical experiments were dropped and the drugs of the salvarsan series are now employed for the treatment of protozoal infections alone. The question of their use for other purposes is once more raised by Dr. Leonard Colebrook's report [1] to the Medical Research Council, which describes an attempt to ascertain their effect on streptococcal infections. The work has been undertaken in a very thorough and careful manner with adequate controls, and the conclusion is reached that a small group of trivalent arsenicals differ very decidedly from almost any other known compound hitherto used in bacterial infections. It is clearly demonstrated that the toxic effect of these substances on the human leucocytes is much less than on certain microbes, such as the hæmolytic streptococci, so that it becomes possible, by suitable adjustment of the doses, to avoid a harmful effect on the leucocytes, while at the same time the drug has an antiseptic action in the blood stream. Dr. Colebrook says that, "broadly speaking, the destructive affinity of these drugs for hæmolytic streptococci is greater than for human leucocytes—that is to say, stronger solutions are required to produce leucotoxic effects than are necessary to kill streptococci." It would appear, therefore, that good results may be expected from this form of treatment. The compounds so far tested may, it is stated, be placed in the following order of increasing toxicity for human leucocytes: metarsenobillon, kharsulphan, and sulfarsenol, approximately equal; stabilarsan; salvarsan; neosalvarsan; and lastly, silver salvarsan. Unfortunately it is found that the leucocytes of patients suffering from streptococcal infections are much more sensitive to the action of these arsenical

[1] A Study of Some Organic Arsenical Compounds with a View to their Use in Certain Streptococcal Infections. By Leonard Colebrook, M.B., B.S. Lond. Bacteriological Department, Medical Research Council. Special Report Series No. 119.

compounds than are the leucocytes of normal people. The problem which Dr. Colebrook has been studying is particularly well suited to the technique evolved in the laboratories of Sir Almroth Wright, but as the result is somewhat tentative, it is difficult to assess the clinical value of the work so far accomplished.

MEMORIAL FUND TO SIR DAWSON WILLIAMS.

IT was naturally decided, and very rightly, that the movement for a testimonial to Sir Dawson Williams, which was started the week before his death, should continue, and that the resulting fund should be employed in the institution of a memorial to him, connected in some intimate and fit manner with the advancement of medicine. The fund will remain open for a time in order that answers to the appeal may be awaited from medical men resident abroad. All who wish to be included in the lists, the first one of which will be published shortly, are requested to send their contributions at once to Sir StClair Thomson, 64, Wimpole-street, London, W., to whom cheques should be made payable, while the envelope should be marked "Dawson Williams Testimonial."

MEDICAL EDUCATION.

IT is often said that academic teachers have too much say in medical education and practising doctors too little. The reply that medical education is an educational and not a professional problem and should therefore be dealt with by educational rather than professional experts is probably not altogether sound in medicine or in the other technological subjects of university training. However that may be, the Commission on Medical Education, which has its headquarters in New Haven, U.S.A., gives in its second report a very interesting account of its attempt to obtain the views of medical men in ordinary practice on the subjects with which the Commission concerns itself. A circular was sent out to a number of doctors named by their local medical societies as successful practitioners and over 1600 replies were received. These were divided into three groups, the first graduating before 1900, the third in 1911 or later. Owing to the rapid changes which have taken place in medical education in America, these three groups had themselves received very different training. Thus only 20 per cent. of the first group had had as much as four years' instruction (i.e., beginning with anatomy and physiology) against 100 per cent. of the third group, 53 per cent. had had no pre-medical university teaching compared with 18 per cent., 61 per cent. had held no house officership against 8 per cent., 70 per cent. were in independent practice when they were 25 years old compared with only 6 per cent. But when the medical men trained in these diverse ways stated their opinions as to what training was desirable, there was remarkable unanimity, whether they had themselves experienced what they recommended or not. Thus over 90 per cent. in all three groups consider pre-medical university work desirable, nearly every one thinks a four-year medical course necessary, and an internship desirable. What was good enough for them is not good enough now. But while these practitioners think well of some of the main changes which have overtaken the curriculum, they are, of course, far from satisfied with the present arrangements. The overcrowding of the course and consequent absence of time for study, undue emphasis on laboratory work, too much attention paid to rare and too little to common diseases are among the most frequent criticisms. At the same time the Commission reports that it is generally appreciated that the acquisition of a proper philosophy of scientific method by the student during his training will largely determine the level of his practice in the future, and there is no serious suggestion that the course should be focused on practical problems alone. Many doctors reported that they had received signal and fruitful inspiration from one teacher or another, and most of those who answered the question about the essential ingredients for success in practice put character and hard work first. The report, with all the details which it gives, deserves careful study because it represents the aims of the average good-class practitioner and not those of the avowed reformers and reactionaries who alone are commonly vocal.

SERUM TESTS FOR SYPHILIS.

THE Meinicke micro-reaction, on which Dr. David Prentice reports in our present issue (p. 493), represents a further stage in the search for some simple and quick modification of the Bordet-Wassermann test for syphilis—a search which has already resulted in the development of the Sachs-Georgi, the sigma, and the Kahn tests. The reaction may be performed either macro- or microscopically; and while Dr. Prentice's paper deals with the latter method a full account of the macro-reaction by Dr. E. A. Rucker and Dr. L. E. H. Whitby may be found in the February number of the *British Journal of Experimental Pathology*. In its barest essentials the technique consists in the admixture of a certain quantity of the serum to be examined with a certain quantity of a special "antigen." Full details of the preparation of the antigen are given by Rucker and Whitby, but those who wish to perform only a limited number of tests will probably find it easier to procure it from Meinicke's laboratory. As the reaction depends upon precipitation, and the complement is not concerned, the serum to be examined requires no preliminary inactivation. The report given in both papers is favourable, and in the hands of these three observers the reaction gave results closely approximating to those of the Wassermann test. Rucker and Whitby point out, however, that they obtained no evidence that the Meinicke reaction is more sensitive than the Wassermann, which makes them regard it as definitely less sensitive than the sigma. For the present there is obviously no question of the Meinicke reaction or any of its precursors replacing the Wassermann reaction in the diagnosis of syphilis, but in its microscopic form, which requires only a few drops of blood withdrawn by puncture of a finger, it has great advantages in pædiatric and asylum practice. The macroscopic technique, furthermore, seems to be an advance on all previous reactions of its kind and certainly marks an important step towards a method which will send the Wassermann reaction into honourable but unregretted retirement.

MEDICAL AND DENTAL REGISTERS.

WE have received from the General Medical Council the three official registers for the year 1927. The Medical Register, among its 102 prefatory pages, includes the amending Act of 1927 giving effect to the mutual registration as between Great Britain and the Irish Free State. In this section the important warning notices have been revised and brought up to date, the warning in regard to association with uncertified women practising as midwives having taken more precise form in view of recent legislation. In the warning notice addressed to dentists has been inserted a paragraph on dangerous drugs, similar to that addressed to the medical practitioner. The only other substantial addition to the prefatory section is a somewhat melancholy table showing the several British possessions and foreign countries with which reciprocity formerly existed and no longer exists. Belgium, of course, renounced this kind of coöperation seven years ago, but the Canadian provinces of New Brunswick, Ontario, and Saskatchewan have thought better of their reciprocity within the past two years, and in the case of Ontario the change has only just come into force. The number of persons on the Medical Register at the beginning of the present year was 53,769, being an increase of 1155 on the previous year. During the year 1927 1941 names were added to the Register, 971 in England, 462 in Scotland, 274 in Ireland, 215 and

the Colonial and Foreign Sections. At the same me 71 names were restored to the Register and 035 removed, 840 on evidence of death, 2 on ceasing practise, 191 under Section XIV. of the Medical ct as having failed to reply to the Council's inquiry, nd 2 were erased by order of the Council. The entists Register, besides containing a convenient cord of the various Acts relating to dentistry, ts out in full the regulations of the Dental Board, ith an appendix of forms for dental registration. he total number of names on the Dentists Register the close of the year 1927 was 14,576, being an crease of 181 on the previous year. The number names added by registration during the year was 0 in the British list and one in the Colonial list. f these, 363 registered with qualifications and 38 nder the Dentists Act, 1921. At the same time 5 names were restored to the Register and 575 moved, 135 on evidence of death, 2 on ceasing to actise, 429 for non-payment of registration fees, on failing to reply to the Board's inquiry, and names were erased by order of the Medical Council. he Dentists Register contains a classified local t of dental practitioners which has special value ving to the disappearance of the names of dental rgeons from Churchill's Medical Directory and e discontinuance of the Dental Surgeons' Directory. he Medical and Dental Students' Register shows at 1214 medical students and 244 dental students gistered during the year. In the case of medical udents the number has apparently settled down to a vel adequate to supply the annual loss from death or tirement; an entry of under 250 will certainly not ffice to maintain the level of dental practitioners at s present figure. All three Registers are published for e General Medical Council by Messrs. Constable and ., 10, Orange-street, London, W.C. 2, the prices being *s.*, 12*s.*, and 7*s.* 6*d.* respectively. It may be noted at copies for previous years are available at the eatly reduced figures of 5*s.*, 1*s.*, and 2*s.* respectively.

THE HEATING OF BUILDINGS.

LIKE their ventilation, the heating of buildings is t to be haphazard. Of the several methods ployed, the most popular is, of course, radiation m coal fires, gas fires, or electric radiators, and is method has many supporters who claim that is pleasant and exhilarating because the rays do t warm the air through which they pass so much the objects on which they impinge. The opposite m of heating is the introduction of warm air the plenum system; the process is here reversed, ce objects in the room are warmed by heated air stead of the air being warmed by heated objects. t-water pipes and steam radiators have much e same effect as hot air, for they chiefly transmit rmth through currents of air heated by contact th them, and only to a minor degree by radiation. ite recently a new method of radiant heating has en introduced, in which large surfaces or panels, sh with the surface of ceilings, walls or floors, are rmed by concealed coils of hot-water pipes. The tensity of the radiation so obtained is some 1400 nes less than that from a fire at about 2000° F., so at panel-heating is hardly in the same category as at from fires. Thus it is somewhat misleading, say the least, to suggest that the radiant warmth m a ceiling approximates closely to the effect oduced by sunshine. On the other hand, the thod deserves consideration, if only because coal gas fires are not suitable or economical for heating ge buildings, and a useful report [1] just issued by e Industrial Fatigue Research Board describes an vestigation of its application to offices and factories. account is first given of the Moll thermopile, ed for measuring the amount of radiant heat emitted from various surfaces, and details are then supplied of a large number of observations made, and sensations recorded, under varying conditions produced by wall-panel heating, ceiling-panel heating, under-floor heating (studied in the new Liverpool Cathedral), panel heating in factories, and high temperature radiations. The most characteristic feature of panel heating was found to be an even distribution of heat over the room, the air temperature of which might not vary more than 1° to 2° F. at any position or level; with hot-water radiators and plenum systems the air temperature near the ceiling may be 10° to 20° warmer than it is near the floor, thus leaving the inmates' feet too cold and their heads too warm. Generally with panels the walls, ceilings, and floor are about 3° warmer than the air, whilst with hot-water radiators the reverse holds good. Direct panel radiation is said not to have caused any definite subjective effect, such as is experienced when gas or coal is used, and whilst it was found that rooms heated by fires felt comfortably warm when 7° cooler than convection-heated rooms, the permissible reduction of air temperature in panel-heated rooms was less than 1°. Panel heating, without claiming comparison with the sun's rays, is held to have a great future, and it may come to replace hot-water radiators and plenum air installations. In big rooms, however, any system of radiant heating ought to be supplemented by small hot-water radiators before each large window, so that down-drafts of cold air may be counteracted.

A HUNTERIAN CELEBRATION AT ST. GEORGE'S.

THE Hunterian Society of St. George's Hospital celebrated the 200th anniversary of John Hunter's birth by inviting the Hunterian Society of London to a conversazione on March 1st, when Sir Humphry Rolleston and Sir Crisp English delivered short addresses. This was a time of centenaries, said Sir Humphry. The four most famous names in British medicine were those of William Harvey, Thomas Sydenham, John Hunter, and Joseph Lister, and whilst the centenary of Lister's birth had been celebrated last year, the tercentenary of the publication of Harvey's "De Motu Cordis" would be commemorated in two months' time. It was fitting that Harvey and Hunter, both of them experimental philosophers, should be linked together in grateful recollection. Hunter was the first to describe the circulation in crustaceans and insects, just as Harvey discovered the circulation of the blood in the higher animals; Hunter, like Harvey, studied the earliest stages of life, and was responsible for the dictum that "embryology indicates the steps by which higher forms in a group of animals have been evolved from a lower." The more he was known the more wonderful did he seem, and as the years went by his intellectual stature seemed only to grow grander; anatomy, physiology, pathology, surgery, and biology in its widest sense found in him their master. But though his influence covered so wide a field, it remained specially appropriate that his bicentenary should be celebrated at St. George's Hospital, of which he was the chief glory, and where he first instituted clinical teaching in surgery. Sir Humphry concluded by referring to Hunter's burial in Westminster Abbey and to Gilbert's bronze bust which adorns the entrance to the St. George's out-patient department. Sir Crisp English then gave a graphic sketch of the places with which Hunter was associated, from his home in Scotland, where he worked for a while as a cabinet-maker, to St. George's Hospital, where, as a surgeon, he practised, taught, and died. He was a man without the advantages of education and culture, which accounted for his roughness of manner and perhaps his difficulty in getting on with his colleagues. But the pupils who had written of their master knew more of Hunter than his critics did, and it was impossible for us to-day, looking at his portrait, not to believe that their appreciation was justified. In his spacious house at Earl's Court Hunter had

many sorts of animals devoted, like himself, to science, and Sir Crisp showed drawings of the house and of the boiler in which Hunter prepared his skeletons, including that of the Irish giant now in the Hunterian Museum of the Royal College of Surgeons of England.

During the conversazione there was a display of many interesting specimens and letters.

THE COMPOSITION OF BOROCAINE.

ANNOUNCED some two years ago under the title the Borocaines: a New Class of Local Anæsthetics, these compounds entered the medical world with a certain éclat. Borocaine, or ethocaine borate, was claimed to be less toxic than the corresponding hydrochloride, novocaine, since its alkaloid content was only about two-thirds as great. It was also said to be ten times as effective as novocaine, and more powerful even than cocaine, a claim that clinicians have not been able to support. The real interest in the discovery was that it was something new. A careful investigation[1] of this claim by Dr. G. W. Collins leads him to the conclusion that the borocaine of Copeland and Notton is identical with the novocaine borate prepared by Einhorn and Uhlfelder, described by them in 1910, and used by Gros in 1911. The average medical reader is hardly qualified to weigh evidence in a matter involving the composition of a complex organic ester, and is naturally disposed to attach much weight to the opinion of Sir William Pope as to the true formula of borocaine. But the facts Dr. Collins adduces in support of his thesis, and of the formula, $C_{13}H_{20}O_2N_2.5HBO_2$, which he considers represents the borate synthetised by both groups of workers, are apparently conclusive, and have already met with acceptance in America. The various claims may be summarised thus:—

—	Formula.	Percentage of boric acid (theoretical).	Melting-point (actual) Cent.
Einhorn and Uhlfelder..	$C_{13}H_{20}O_2N_2.4B(OH)_3$	50·1	160°
Copeland and Notton ..	$2(C_{13}H_{20}O_2N_2)4H_2O,5B_2O_3$	47·2	168°
Watson-Williams (E.)	—	—	166°
Collins.. ..	$C_{13}H_{20}O_2N_2.5HBO_2$.	48·2	166°

Borocaine is, we believe, protected by patent, but it is a little difficult to discover in its preparation the element of newness essential for such protection. The process of synthesis consists of mixing in solution molecular proportions of the base and the acid, an old-established method. Possibly the use of acetone as a solvent was a novelty, but that hardly seems essential for the production of ethocaine borate.

CONGRESS OF THALASSOTHERAPY.—The fifth annual international congress of thalassotherapy will be held at Bucharest and Constanza from May 21st to 29th.

A CONFERENCE ON RHEUMATIC DISEASES.—On May 10th and 11th next a conference on rheumatic diseases will be held at Bath under the presidency of Sir George Newman, Chief Medical Officer to the Ministry of Health. The conference will be divided into three sessions. The first, over which Lord Dawson presides, will deal with the social aspects of the disease; the second, presided over by Sir Humphry Rolleston, will deal with causation; and the third, presided over by Sir Farquhar Buzzard, will discuss treatment. Many leading authorities on rheumatic diseases have promised to contribute papers on various aspects of the subject, which is felt to be one upon which both the medical profession and the public require information and guidance. The hon. medical secretary of the conference is Dr. Vincent Coates, 10, The Circus, Bath, and the hon. organising secretary, Mr. John Hatton, who may be addressed at the Pump Room, Bath.

Modern Technique in Treatment

A Series of Special Articles, contributed by invitation on the Treatment of Medical and Surgical Conditions

CCLXVI.—TREATMENT OF DIVERTICULITIS OF THE COLON.

OBSERVATIONS of recent years have shown tha the occurrence of diverticula of the large intestin (" diverticulosis ") is comparatively common, and tha these diverticula become inflamed and give rise to variety of pathological and clinical conditions. Th diverticula are hernial protrusions of the mucou membrane through the muscular coat of the bowe and they may project from its peritoneal surface or ma be hidden in the fat between the layers of the mesocolo or in appendices epiploicæ; they are usually preser in large numbers and affect most commonly the pelv colon, but they may also be found with some frequenc in the descending colon and in the transverse colon t the left of the middle line.

Pathological Changes.

Diverticulitis is essentially a disease of later midd life, between the ages of 45 and 65; the condition commoner in men than in women and affects f people more often than thin. Many of the patien suffer from chronic constipation, and it is likely tha the resulting distension of the colon plays some pa in the development of the hernial protrusions. Th openings of the diverticula into the lumen of the bow are very small, and they may easily be overlooke even at a post-mortem examination.

Illness associated with the presence of diverticu is generally caused by inflammation of their walls ar of the tissues with which they are in contact. The may be retention of fæcal material in the diverticul causing spasm of the colon; infection causing sma abscesses in the wall of the bowel; or perforatic leading either to diffuse peritonitis or a localise abscess or fistula. Such fistulæ may communica with the surface of the body, with the bladder, with other parts of the bowel. In another class cases chronic inflammation leads to great thickenir and sclerosis of the affected loop of colon, close simulating carcinoma and causing partial or comple intestinal obstruction. There is some evidence suggest that carcinoma is liable to develop in segment of gut affected by chronic diverticulitis.

Varieties of Clinical Picture.

As the result of these pathological changes number of clinical pictures may be produced ar diagnosis may be difficult and delayed until a la stage of the disease, not only because the condition insidious but also because it simulates a number more common diseases. The clinical varieties mc often seen are: (*a*) attacks of subacute inflammati associated with temporary spasm of the colo (*b*) the formation of a localised abscess in the pelv or left iliac region; (*c*) the development of an extern fistula in the left iliac region; (*d*) diffuse perforati peritonitis; (*e*) involvement of the urinary bladd by adhesions, cystitis, or the formation of a vesic colic fistula; and (*f*) chronic and acute obstructi of the colon.

(*a*) *Attacks of subacute inflammation.*—The patie who perhaps has noticed an increasing tendency constipation, is seized suddenly with pain of modera severity in the left lower quadrant of the abdome referred in some cases to the perineum, groin, or pen The pain is spasmodic in character and increases severity during the first few hours; it is made wor by exercise, and particularly by jolting—a somewh characteristic symptom. The bowels are confined a the temperature rises to between 99° and 100° If the patient lies up and the bowels are cleared t first attack will, as a rule, subside within a week a leave him apparently in his usual good health.

Palpation of the abdomen in the early stages the attack will reveal tenderness and possibly slig rigidity above the pubes just to the left of the midc

line. On bimanual examination a tumour can be felt, usually about the size of a small orange, high in the pelvis, and sufficiently movable to allow of its being pushed down on to the finger in the rectum; it is tender to the touch below as well as above. Active movements of the hip may elicit pain. If the attack subsides without the formation of an abscess the tumour gradually shrinks and usually becomes impalpable within ten days.

In the diagnosis of early cases X ray examination is often of great value. Two observations may be made: (1) A barium enema sometimes reveals a narrowing of the lumen of the gut for two or three inches in the inflamed and spasmodic area, the film even showing no barium here though the colon above and below is filled. (2) A barium meal may show numerous diverticula extending up the descending colon, which appear as small opaque areas about the size of peas, persisting after the main bulk of the barium has been evacuated. On the other hand, a negative X ray finding does not exclude diverticulitis, for the barium in the pelvic loop or rectum may mask the defect, and it is sometimes only on repeated examinations that the barium will enter the diverticula, because of the small size of their mouths, and because they may already be loaded with stiff fæcal material. Sigmoidoscopy is of little value in the diagnosis of diverticulitis, except in some cases by excluding new growth. The thickened inflamed loop does not allow the sigmoidoscope to approach it easily, and the openings of the diverticula into the bowel are so small as rarely to be visible.

During the attack the patient must be kept in bed on a light diet with plenty of fluids, and the contents of the large intestine must be liquefied as early as possible by large doses of a saline aperient; the bowel should be washed out by simple enemata, which must be given slowly and carefully, as they are apt to cause pain, and any sudden tension would be dangerous. After the attack has subsided further trouble may be warded off by the initiation of a régime which should be continued indefinitely. This has two main objects—the production of a bulky food residue in the colon and at the same time the reduction of this residue to a liquid form, of about the same consistency as that usually present in the small intestine. For this purpose an ounce of liquid paraffin should be taken three times a day and may be expected to produce two or three loose actions of the bowel daily. Should the patient at any time become sufficiently constipated to form a hard stool he should at once take a large dose of a saline purgative so as to produce watery motions. Any carelessness in this respect is likely to be at once followed by another attack of inflammation, which may go on to the formation of an abscess. As to diet, the patient must carefully avoid all fruits which contain small seeds (and these unfortunately are the most attractive to many people), such as figs, currants, strawberries, raspberries, and gooseberries; the seeds of these are small enough to enter the tiny mouths of the diverticula and produce inflammation. The foods that produce a bulky residue and prevent spasm of the colon are to be encouraged, such as brown bread, oatmeal porridge, and vegetables.

(*b*) *Abscess formation.*—Any attack of diverticulitis may go on to perforation and the production of a localised abscess, which will usually be situated either on the left side of the pelvis or in the left iliac fossa. Such abscesses require drainage, and this will usually be followed by a temporary fæcal fistula; the operation wound of the abdominal wall may be expected to become heavily infected, and the incision therefore should as far as possible be planned to allow for this, a short oblique or transverse cut being much preferable to a vertical one.

(*c*) *Fistulæ* in the left iliac or hypogastric region not only follow the drainage of an abscess, but may open spontaneously. In such cases a transverse colostomy will usually be necessary, but sometimes it is possible to short-circuit the affected segment of colon.

(*d*) *Acute diffuse peritonitis* from the perforation of a diverticulum or the rupture of a peri-diverticular abscess is the most dangerous complication of the disease, for the patients collapse rapidly from the severity of the toxæmia. They are not able to withstand a prolonged operation, and gas-oxygen and local anæsthesia are strongly indicated. The peritoneum must be drained, and, if the patient's condition will allow, it is advantageous at the same time to perform a colostomy above the site of the perforation.

(*e*) *Vesical complications.*—Diverticulitis of the pelvic colon not uncommonly involves the bladder, adhesions between the two viscera and the migration of bacteria from the colon causing chronic cystitis, with pyuria and frequency of micturition, and acute exacerbations from time to time; considerable general debility and cachexia are usual. In such cases the intestinal symptoms and signs may very easily be masked by the more obvious urinary ones, but a careful bimanual examination is likely to reveal the presence of the typical inflammatory tumour. If a vesico-colic fistula forms the patient will pass fæcal material per urethram, and his condition will rapidly deteriorate; cystoscopy is made difficult by the heavy infection of the bladder, but it may be possible to see the fistulous opening in its wall and to distinguish it from a malignant fistula by its more clean-cut edge. Where there is merely intermittent cystitis from adhesions this may be cleared up by initiating the régime of diet and aperients laid down above and by the administration of urinary antiseptics. For a vesico-colic fistula a colostomy should be performed.

(*f*) *Chronic and acute obstruction* resulting from diverticulitis are often indistinguishable from the forms due to new growths, and it has in fact been shown that a number of tumours due to diverticulitis have been excised in the belief that they were cancers of the colon. A diagnosis of diverticulitis as the cause of chronic obstruction—with diarrhœa, alternating constipation and diarrhœa, or constipation alone—may be suggested by a history of attacks of recurrent spasm and inflammation over a period of years. The symptoms of actual obstruction may be of longer standing than would be likely in a case of carcinoma; there is less cachexia, bleeding is less common, and a tumour is more often to be felt, slightly tender, movable, and usually as big as an orange. The presence of so large a mass without fixation would be strongly in favour of diverticulitis as against new growth. The treatment of such a case is to short-circuit the site of obstruction, if it is sufficiently high to allow this; for instance, for obstructive diverticulitis of the left half of the transverse colon the proximal part of the transverse colon may be joined up to the pelvic loop, and for obstruction at the upper part of the pelvic colon the transverse colon may be anastomosed to the lower part of the pelvic colon. If, as is often the case, the inflammatory mass is too low to allow of a short-circuit, a colostomy must be performed.

When diverticulitis causes acute obstruction the symptoms are those typical of obstruction of the large intestine; there is much distension, late vomiting, and the cæcum is palpable when in peristalsis, whilst it may be possible to feel the mass formed by the inflamed loop of bowel. For such patients a colostomy will usually be necessary, but occasionally they are fit enough to stand a short-circuiting operation; in this case it is advisable as a precaution to perform a temporary cæcostomy at the same time.

Fortunately, after drainage of the colon above a mass due to diverticulitis the lumen of the bowel at the site of the obstruction tends gradually to be restored, and a vesico-colic fistula will close; so that in some instances it is possible later on to close the colostomy. The bowel does not usually recover its lumen in less than three years, and in deciding whether the time has come to close the colostomy an X ray examination will, of course, be of great help. After such an operation the patient must carry on the régime described for early cases.

C. W. GORDON BRYAN, *M.C.*, F.R.C.S. Eng.,
Surgeon (with charge of Out-patients), St. Mary's Hospital, and the Hampstead General and North-West London Hospital.

Special Articles.

LIVER EXTRACT FOR THE TREATMENT OF PERNICIOUS ANÆMIA.

(Preliminary Report by the Medical Research Council.)

THE treatment of pernicious anæmia by addition of liver to the diet, introduced in America by Minot and Murphy, has already been widely adopted with encouraging results. An important development of this has recently become possible through the successful preparation, by Cohn and others, of an extract of liver containing in small bulk the unknown factor which produces the ameliorating effect. The treatment is thereby made available for patients who cannot tolerate the large daily consumption of liver itself.

Source of the Extract.

In the past autumn, through the courtesy of the Pernicious Anæmia Committee of Harvard Medical School, the Medical Research Council received information about this method of preparing liver extract, and were invited to make trial of it with a view to assisting introduction of the treatment in this country. On the basis of this information experimental work was undertaken in the Council's laboratories at the National Institute for Medical Research, and a modification of the American process was found, through the coöperation of Prof. F. R. Fraser, of St. Bartholomew's Hospital, to yield a satisfactory extract. To increase the scope of the work the Council then invited the coöperation of manufacturing firms likely to be interested, and arrangements were made for clinical trials of the preparations thus obtained in adequate quantity.

Supplies of liver extract made on a manufacturing scale by the modified process were received from the Boots Pure Drug Co., from the British Drug Houses, Ltd., and from Messrs. Burroughs Wellcome and Co.

It is at present impossible to gauge the therapeutic effects of liver extracts in pernicious anæmia by any other method than that of direct trial upon human patients. The extracts supplied by the three firms were therefore distributed widely to various hospitals, and clinical reports upon the activity of the several preparations have been received from the following physicians: Dr. John Cowan, Glasgow; Dr. S. P. Davidson, Edinburgh; Prof. E. C. Dodds, Middlesex Hospital; Prof. T. R. Elliott, University College Hospital, London; Prof. A. W. M. Ellis, London Hospital; Sir Thomas Houston, Belfast; Prof. W. E. Hume, Newcastle-on-Tyne; and Prof. E. Mellanby, Sheffield. To these, and the colleagues who have been associated with them in this work, the Council are much indebted.

Results in 34 Cases.

A total of 34 apparently clear cases of the disease came under treatment. The object of the trials was to test the activity of each extract as rapidly as possible rather than to watch the results over a long period of time. For this purpose the early increase in the count of reticulocytes, the young red cells with special staining properties, was adopted, as it had been found to be satisfactory in the American work. This rise is usually associated with clear sensations of improvement on the part of the patient, and it is succeeded by a progressive increase in the general red cell count while the relative proportion of reticulocytes diminishes.

Out of the 34 cases all but two showed a good response. In 23 of these the conditions were such that other reasons for the improvement than the administration of the extract were clearly excluded. In the remaining nine the response during treatment was n less marked, but the possibility of natural remission or of the influence of other treatments, such a previous administration of fresh liver, rendered th conclusion less certain. The daily dose of extrac corresponding to half a pound or 250 g. of live generally brought a clear rise in reticulocytes, cu minating about the twelfth or fifteenth day; doubl that amount daily excited an earlier reaction, with maximum as early as the fifth day. As illustratin the remoter benefit in a case that had been treate with only the smaller doses, but over a longer perioc the total red cell count rose from 750,000 to 5,000,00 in 34 days.

These effects are identical with those obtained wit liver itself, although the effect of a given dose of th extract is not so great as that of the quantity of live from which it is derived. Time has not yet permitte an estimate of any possible deterioration of the extrac on keeping.

Suggested Line of Further Progress.

These preliminary reports enable the Medica Research Council to state that the preparation submitted have been found to be satisfactory. Th process used in making these extracts has not neces sarily any peculiar value as compared with possibl alternatives, but it is one capable of ready applicatio on a large scale. The Council believe that furthe progress will be best facilitated if extracts of the typ which they have investigated are now made available along with any others introduced apart from th Council's action, to the medical profession in genera

It is understood that supplies of these liver extract will at once be obtainable, through the usual com mercial channels, from the firms already named. Th Council are not themselves able to deal with an applications for the material.

MEDICINE AND THE LAW.

Encephalitis Lethargica.

Is encephalitis lethargica a disease of which th incidence is attributable to lowered vitality? Is i more likely to attack a patient whose general powe of resistance to disease has been lowered? If so, i might be an additional ground for awarding damage in an action arising out of injuries due to a motorin or railway accident. It has, in fact, been made th basis of a claim last month under the Workmen Compensation Act, but if it were to be regarded a among the natural sequelæ of lowered vitality, i might figure in many other kinds of claim and insuranc companies would find their commitments correspond ingly increased. On Feb. 15th a collier, aged 25, wh had been injured in a mine and had subsequentl suffered from encephalitis lethargica, claimed com pensation in the Wrexham County Court from hi employers on the ground that the latter disease coul be regarded as part of his "accident" arising out of hi employment since the injuries for which his employer admittedly had to compensate him had lowered hi power of resistance. Medical evidence was given i support of his claim, but Judge Roberts (who had th assistance of Dr. Geoffrey Williams, of Wrexham, a medical referee) did not regard the claim as based upo a sound medical foundation. Dr. H. Cohen, o Liverpool, a witness called by the employers, state that he had knowledge of 1200 cases of sleepy sickness and that in no single case was the onset of the disease attributable to lowered vitality. The disease, he said attacked people without regard to their state o health.

Hygiene in Barber's Shop.

A plaintiff has been awarded £150 damages an costs against a South Tottenham hairdresser fo what the jury has found to be negligence on th part of the defendant. The plaintiff had his hai cut and, in the final trimming of the hair above th

ears with a razor, the barber's assistant cut the skin. Two days later the plaintiff's face began to swell and presently it was found that he was suffering from erysipelas and septic poisoning. He said the sponge used on his face was kept in the basin opposite his chair; so far as he could see, the materials were not sterilised; the razor was not placed in hot water but was merely stropped. A hairdresser employed by the defendant described the practice in the shop as follows. As soon as a customer had gone the instruments were dipped into a disinfectant fluid, and were then wiped and put aside for the next customer; sponges, after being dipped in the disinfectant, were rinsed; cuts were dealt with by sponging the wound and applying an antiseptic stick, which had previously been dipped in the disinfectant. Evidently the jury considered that this hygienic ritual had not been fully observed when the plaintiff was injured, or that it was inadequate. Dr. M. J. Cronin, who had attended the plaintiff, said it was a fair inference to attribute the erysipelas from which the plaintiff suffered to the way in which the cut had been treated. As a matter of law a hairdresser, cutting a customer's hair for money, must, of course, use proper skill in his calling; he must also see that his materials and treatment are antiseptic. Such a verdict will direct the attention of barbers to their liability.

Ordeals of Jury Service.

While a medical witness was giving evidence in a murder trial at Derby Assizes the other day a juryman collapsed and was removed in a fainting condition. The witness had been identifying a carving knife which he found stuck in the victim's throat. After some delay a doctor returned to court and stated that the juror had been upset by the ghastly details. "Tell him to bear in mind," said Mr. Justice Hawke, "that even more detailed description of what occurred as still to be given; the strain will come later." After a further adjournment the doctor informed the judge that it would be unwise for the juror to resume his duties. Under recent legislation there is power to continue a trial in the circumstances notwithstanding a juror's illness provided that both the prosecution and the defence agree to this course. Apparently there was no such agreement, for a new juryman was taken in, the whole jury was sworn afresh, and the case recommenced.

There must be many jurors to whom the task of listening to unpleasant details is physically repugnant and nauseating. The nature of the evidence is a ground on which a woman juror has a statutory right to apply to be excused from jury service. The words refer perhaps rather to reasons of delicacy in relation to sexual matters, but they would cover any case of an unpleasant or disgusting nature. When summoned to attend a court as a juror, nobody can tell beforehand what the cases will be about. Would a male juror, if of highly-strung temperament or neurasthenic type, be entitled to exemption from jury service on medical grounds? Or must he do his duty at the risk of collapse? The viewing of a dead body by a coroner's jury is an ordeal which is no longer indispensable. Under Section 14 of the Coroners (Amendment) Act of 1926 the coroner himself must view the body but the jury need not do so unless the coroner so directs or the majority of the jury so desire. This change in the law was advocated by the late Sir Mackenzie Chalmers, who was for many years chairman of the Coroners Law Committee established by the Home Office. He personally attended inquests and watched the conduct of jurors when viewing the corpse. The better class of jurors, he averred, evaded their duty of looking at the body while the more morbid-minded gazed their fill. Though there have been indications that not all coroners approve the relaxation of the jurors' duty to view, this amendment of the law should mean that in practice the jury will be spared the ordeal of the view unless there are wounds, the sight of which might help to determine an uncertainty as to whether they were self-inflicted or not.

ROYAL INSTITUTE OF PUBLIC HEALTH.

The Present State of the Care of the Insane and the Mentally Defective.

Sir Frederick Willis took the chair on Feb. 29th, when Sir Robert Armstrong-Jones, Lord Chancellor's Visitor in Lunacy, delivered a lecture on this subject. The present conditions, he said, were unsatisfactory for both classes. The insane, owing to the relative lack of provision for voluntary treatment, came under certificate too soon; the mental defective was certified too late, as there were no places available to receive him. There was one law for the rich and another for the poor; the rich man who cared to be treated as a voluntary patient could go in and out as he liked, but the poor man had to wait until he was certified, and had to wait longer before he could get out. These, with other differences, constituted an injustice to democracy, and the present distrust of the system had resulted in the appointment of a Royal Commission, whose report went a long way to reassure the public mind, but left something to be desired in its suggestions for reform.

Need for Voluntary Treatment.

The exclusion of voluntary patients from public asylums was an anomaly. One of the great points urged in the report had been the necessity for the earliest possible treatment of all mental patients The recovery-rate for all cases was 40–50 per cent., and after early treatment it was 70 per cent., if all forms of threatening insanity were included. Many large teaching hospitals maintained psychiatrical out-patient departments, but a very large proportion of patients required ward treatment. For every certified patient there was one on the borderline, ready to be precipitated into the certified and probably permanent group if treatment were delayed. Insanity cost the country over £20,000,000 a year, and its prevention depended on early treatment. The Royal Commission had stated that certification should be the last resort, and not the pre-requisite of treatment, and had recommended that voluntary patients should be admitted into general hospitals, nursing homes, and private care.

The "Non-Voluntary" Patient.

It was, however, a serious defect in the report that it did not allow for a "non-voluntary" class of patients as well as a voluntary and an involuntary class. The will-power of a mental patient often became so malleable that it would readily yield to a superior will against the best interests of the patient and his friends; the patient was then non-volitional. but not involuntary. It was therefore important that the Board of Control should not only have cognisance of all voluntary patients, but should be able to have immediate access to them and should inspect the conditions under which they resided. The number of voluntary patients was now 1127, and if the voluntary system became general the total would probably reach 20,000. The Commission had put forward the "Provisional Treatment Order" as a means of bringing the non-volitional patient under treatment, but the three visits from a justice within one year might be prejudicial to the patient and should be made discretionary. Another defect of the Order was the stress it laid on prognosis, always a very uncertain factor.

Recent law suits had made it obvious that the certifying medical man needed protection from litigation, and the public from the consequences of a wholesale reluctance by the profession to certify any case. The Commission had proposed that the onus of proof of bad faith or lack of reasonable care should be placed upon the plaintiff, but it was doubtful whether this would afford sufficient protection.

Importance of Prevention.

The Chairman said that seven years' chairmanship of the Board of Control had impressed him with the

fact that the mental health of the nation was not improving. The increase was 2500 to 3000 cases a year, and the incidence- and recovery-rate had been stationary for 30 years. The general health, on the contrary, had greatly improved, and the expectation of life had increased. He realised that it was impossible to dogmatise on this question, but every doctor with whom he had discussed it had said that they had a much better chance of curing a patient if they took him in an early stage. The present law absolutely discouraged the treatment of the great mass of the mentally ill of this country until they became so bad that a doctor certified them as proper persons to be locked up. Until they got to this stage the public authority could not spend a penny on their treatment. The authorities concerned had chafed for years at that restriction, but the lethargy of public opinion had prevented anything from being done. The Royal Commission had reported two years ago, but Parliament had taken no action. Even the rich person, as the law stood, could only go as a voluntary patient to a very limited number of places. If the law were altered it was to be hoped that the number of voluntary patients would be even greater than that suggested by Sir Robert Armstrong-Jones. In spite of this increase the expense to the country would be diminished, since, owing to early treatment, a much smaller number would eventually become insane.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Revival of the Cautery.

Prof. August Bier's recent address at the Berlin Medical Society has caused almost as much sensation as the one on homœopathy which he read a year or two ago. He began by pointing out that Hippocrates regarded the cautery-iron as the most powerful remedy in existence, and his main thesis was that its use should not have been abandoned as it is to-day. The unpopularity of the cautery he ascribes to the fact that it produces ulcers which heal slowly and leave ugly scars, and he therefore recommends that not the skin, but the subcutaneous tissue should be burnt; for this purpose he cuts a flap, raises it, and applies the cautery beneath the skin, later closing the flap by suture. The results of this technique, he said, are excellent, and the wounds heal with insignificant cicatrices.

The red-hot iron is especially useful, he considers, in combating infection. In cellulitis, for instance, after having removed any necrotic tissue, he applies the cautery to destroy bacteria, and then closes the wound with loose sutures. This treatment is said to have checked the progress of cellulitis in all the 222 cases in which he has tried it. One of the results of the operation is a considerable rise of temperature, but this falls again soon afterwards as a result of profuse sweating, and the patient's general condition soon becomes normal again. In the wound itself there is generally a high degree of inflammation with serous and afterwards purulent discharge. After describing the use of the cautery in a number of other surgical conditions, he gave an interesting account of results obtained in medical cases in which a bacterial focus of disease is not directly accessible. In 12 cases of endocarditis lenta sent to him by physicians he made a large flap of skin over the left costal arch and cauterised the subcutaneous tissue; seven of the patients were cured and five died. He concluded his address by stating emphatically that fever and inflammation are powerful remedies which should only be combated when they are excessive, and may well be *induced* in chronic diseases where they are absent. In this connexion he alluded to the use of malaria to cure G.P.I. For many years Director of the Surgical Clinic of the University, Prof. Bier is very popular with the profession in Berlin and he was listened to with the greatest interest by a large audience, although many of its members remained somewhat sceptical.

Salvarsan in Late Syphilis.

The German Dermatological Society has promoted an inquiry into the question whether salvarsan therapy favours development of the so-called meta syphilitic symptoms and of aortitis, as claimed by some authorities. With this object they have sen the following declaration to 130 eminent German and foreign specialists for criticism and comment.

There is no statistical evidence that the increase o paralysis in civilised countries has any connexion with th administration of salvarsan, and the same is true of aortitis The supposition that cases in which less vigorous treatmen has been administered are not so liable to metasyphilis i unfounded. Salvarsan, if cautiously administered, i harmless, and the medical profession should prescrib salvarsan, bismuth, and mercury at an early stage of th disease without regard to unfounded theories.

Of the 130 persons to whom this declaration wa sent, 120 returned it with an expression of agreement Four did not concur in parts of the statement, whils six did not reply at all.

The Campaign against Rheumatism.

The German Association for Combating Rheuma tism, founded a year ago, has just held a meeting i Oeynhausen, the renowned brine spa in Westphalia The secretary reported that special departments fo the study of rheumatism have been established in th hospitals of Aix-la-Chapelle and Wiesbaden and in th university clinics of Berlin and of Leipzig. Th delegate of the Government Health Department, Pro Martinek, stated that rheumatism, though it doe not endanger their lives, incapacitates a greate number of workmen than tuberculosis and involve large public expenditure for their maintenance. Th Government is considering, he said, whether the car provided by the sanitary authorities for tuberculosis venereal diseases, and crippling should not be extende to rheumatic diseases. Prof. H. Curschmann (Rostock spoke on the so-called induration of muscles, whic he believed to be a colloidal change, whilst Pro Müller (Munich) held that it was due to muscula contraction. Dr. J. van Breemen (Amsterdam proposed an international nomenclature for rheumati disorders, and this question was left to a specia committee which will have to submit proposals a the next meeting.

The first trial under the Prevention of Venere Diseases Act took place in Munich on Dec. 31st, whe a syphilitic man was found guilty of having ha intercourse with a woman and infecting her, whil aware that he suffered from the disease. He wa sentenced to one month's imprisonment, but wa discharged on probation.

The German Colonial Society is asking the Foreig Office to propose to the League of Nations tha medical men should be allowed to practise in countri belonging to the League without having to take speci examinations. In some of the mandated territorie it is said, there is a considerable shortage of medic men, which is prejudicial to the health of the nativ population, as is shown by an increase of sleepin sickness, tuberculosis, and malaria. The admission o qualified medical practitioners ought not to b restricted by the Mandatory Powers.

EXTENSION OF SUNDERLAND INFIRMARY.—Recentl an extension of this institution, to be called the Prince Mary Wing, was formally opened. It consists of a thre storey building with 95 beds and has cost £36,000.

WORKPEOPLE'S HOSPITAL FUNDS.—In the si months since its inception 65,000 workpeople have join the Liverpool penny-in-the-pound scheme. Last year th Leeds Workpeople's Hospital Fund raised £43,547, a increase of over £3000 upon the preceding year. One-fif of the population of the city contributes, and the cost administration has been reduced from 10 per cent. at whi it stood a few years ago, to 3½ per cent. The motor acciden admitted to the Leeds General Infirmary have risen fro 758 in 1925 to 1028 in 1927.

Public Health Services.

LOCAL AUTHORITIES AND SANITARY SCIENCE.

THE evidence submitted by the Ministry of Health and other Government departments before the Royal Commission on Local Government has now been published.[1] The Minister of Health submitted a memorandum and Sir W. Arthur Robinson, secretary, and Mr. E. R. Forber, deputy secretary, attended to give evidence. The Minister made it clear that his object was to put forward the weak points in the present system and to leave it to the Commission to devise remedies. The local authorities comprise 83 county borough councils, 62 county councils, and 686 councils of county districts, which include 255 non-county borough councils, 785 urban district councils, and 646 rural district councils. The evidence submitted largely deals with the capacity of the 686 councils of county districts to carry out the duties placed upon them by the many legislative enactments enacted between 1875 and 1926, a list of which is given. Statements taken from the 1923 survey reports of the medical officers of health of 35 urban areas (non-county boroughs and urban districts) and 37 rural districts are submitted as illustrations of the failure of certain councils to discharge their functions. The statements are purposely given without naming the districts. Among the 35 urban areas the chief failures have been with regard to water-supply, sewerage, sewage disposal, the provision of proper sanitary conveniences, and adequate scavenging. Among the 37 rural districts the failures have been somewhat similar, but the absence of proper scavenging assumes a more prominent place. It is pointed out that the number of statements are not to be regarded as percentages but only as illustrations. The memorandum goes on to discuss the reasons why medical officers of health should generally devote their whole time to public duties; why it is undesirable that a sanitary inspector should also act as surveyor; and the existing rate of progress towards the employment of medical officers of health and sanitary inspectors on proper terms. It is shown that in 1873 the proportion of whole-time medical officers of health was about one-quarter, and that now it is slightly over one-third. A statement in the appendix further shows that of the 1686 councils of county districts 120 (or 7 per cent.) have a whole-time M.O.H. of their own, while 385 (or 23 per cent.) have a whole-time M.O.H. jointly with other authorities, and 1181 (or 70 per cent.) have a part-time M.O.H., who is also engaged in private practice.

Infectious Hospitals.—Water-supply.

In spite of the legal provisions which allow the councils of small districts to combine for providing efficient hospitals for infectious diseases, there is much failure in this respect. The complicated and overlapping nature of the duties of the councils of county districts and county councils with regard to maternity and child welfare schemes, the supervision of midwives, the notification of births, the prevention of damage from ophthalmia neonatorum, the school medical service, and the prevention of tuberculosis are described.

The question of determining whether the disability of the council of a county district is due to restricted financial resources or to want of interest is acknowledged to be a difficult one, but it is pointed out that suitable candidates will not emerge from a population below a certain size. On March 31st, 1927, the Minister had not received the 1925 "survey" reports from 69 of the 1686 county districts, and the defaulters included five boroughs, and 32 urban and 32 rural districts.

It is laid down as a paramount principle that local self-government must be encouraged. The difficulties in the way of action by a county council in default of the district council are fully considered. The special need for joint action between the local authorities in district planning and water-supply are pointed out.

It is shown in the report that up to the present there are only two regional advisory committees for water-supplies, one for S.W. Lancashire and the other for the Sherwood area of Nottingham, where it is necessary to consider the proper allocation of the underground water obtainable from the Bunter sandstone. These regional committees are not in any sense a joint water authority, but have purely advisory functions, and serve as a neutral ground where divergent interests can be amicably adjusted.

The report comments on the desirability of considering whether the distinction between the status and functions of the councils of non-county boroughs and urban districts and also between the councils of urban and rural districts should be maintained or not.

In the evidence submitted on behalf of the Home Office it was pointed out that the enforcement of the provisions for the sanitary conditions of workshops are thrown upon the local authorities, and that while the law is fairly efficiently administered in the larger boroughs and urban districts, it is reported by the factory inspectors to be inefficiently administered in many of the small boroughs and urban districts and in most of the rural districts.

Agricultural Problems.

On behalf of the Ministry of Agriculture it was pointed out that 124 non-county borough councils, in addition to the county councils and county borough councils, deal with the Diseases of Animals Acts, and that there is a diversity of interests between urban and rural areas. The former are more interested in having a free meat market, the latter in the health of the stock. A suggested remedy is the formation of joint committees for the geographical counties, which shall include representatives of the county council and all the other local authorities. The Ministry of Agriculture favours the appointment of whole-time veterinary inspectors, but the County Councils Association in October, 1925, passed a resolution that each county authority should decide for itself whether its circumstances required the services of a whole-time veterinary inspector or not.

The Ministry of Agriculture memorandum mentioned the duties thrown on local authorities by the Rats and Mice (Destruction) Act, 1919, but Sir Francis Floud in his evidence did not seem to think that the Act had effected any very marked reduction in the number of rats and mice, or that the powers given to local authorities to destroy the rats and charge the owners with the cost were often exercised. The memorandum also showed that there is much diversity in the provision made by county councils and county borough councils for agricultural education, and Bedford and Huntingdon were mentioned as striking examples of agricultural counties, which did little or nothing. In the Ministry's view every county with real agricultural interests should have a whole-time agricultural organiser and, as a rule, a poultry instructor, a dairy instructor, and a horticultural instructor in addition. Huntingdon has a horticultural instructor and Bedford a poultry inspector. From the point of view of clean milk and the public health an agricultural organiser and a dairy instructor are of first-rate importance.

We do not notice any mention of the duties cast upon local authorities by the shell-fish regulations, although shell-fish are now regarded as a not uncommon cause of typhoid fever.

QUEEN'S HOSPITAL FOR CHILDREN.—The report for 1927 shows that the cost of each in-patient was £3 16*s.* 1*d.* per week, and of each out-patient 5*s.* 3*d.*

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 25TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 392 (last week, 369); scarlet fever, 1799; diphtheria, 1392; enteric fever, 66; pneumonia, 1604; puerperal fever, 55; puerperal pyrexia, 112; cerebro-spinal fever, 7; acute poliomyelitis, 9; acute polio-encephalitis, 3; encephalitis lethargica, 31; dysentery, 13; ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 25 counties:—London, 1; Bedford, 1; Chester, 9; Derby, 11; Durham, 85; Kent, 1; Lancaster, 22; Lincoln, Parts of Holland 1, Parts of Lindsey 12; Norfolk, 3; Northumberland, 14; Nottingham, 6; Oxford, 2; Southampton, 1; Stafford, 7; Suffolk East, 6; Surrey, 1; Sussex East, 1; Warwick, 8; Worcester, 1; Yorks, North Riding 9, West Riding 78; Brecknock, 3; Glamorgan, 41; Monmouth, 68.

The number of patients at the Infectious Hospitals of the Metropolitan Asylums Board on Feb. 28th–29th was as follows:—Small-pox, 16 (1 of these being under observation); scarlet fever, 1746; diphtheria, 2624; enteric fever, 30; measles, 1436; whooping-cough, 167; puerperal fever, 13 (plus 12 babies); encephalitis lethargica, 72; poliomyelitis, 1; "other diseases," 35. At St. Margaret's Hospital there were 14 cases of marasmus and 13 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was 1 death from small-pox, 1 (1) from enteric fever, 117 (66) from measles, 5 (3) from scarlet fever, 36 (6) from whooping-cough, 35 (12) from diphtheria, 51 (6) from diarrhœa and enteritis under two years, and 98 (20) from influenza. The figures in parentheses are those for London itself. Of the 51 fatal cases of measles outside London, 8 were reported from Plymouth, 7 from Sheffield, 5 each from West Ham and Manchester, and 4 from Bristol. The number of stillbirths registered during the week was 258 in the great towns, including 48 in London. The death from small-pox belonged to Bradford C.B.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. A. O'Flynn to *Ganges*.
Surg. Lt.-Comdr. S. R. Johnston to *Dauntless*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. J. F. Whelan, having attained the age fixed for compulsory retirement, retires on retd. pay.

Maj. E. C. Stoney retires with a gratuity.

Maj. R. O'Kelly, half-pay list, late R.A.M.C., retires on retd. pay on account of ill-health caused by wounds.

The undermentioned Capts. to be Majs.: D. Crellin (Prov.) and T. P. Buist.

Capt. (Prov. Maj.) C. H. G. Penny retires, receiving a gratuity, and relinquishes the rank of Prov. Maj.

Lt. J. G. Weston, from R.A.M.C., T.A., to be Lt. on prob.

Temp. Lt. R. Reynolds relinquishes his commn.

The undermentioned Lts. (on prob.) are confirmed in their rank: E. W. Hayward, M. F. N. Griffin, J. J. O'Dwyer, H. A. Ferguson, de L. Carey, M. G. de L'I. Sturm, and D. B. O'Sullivan-Beare.

G. L. Grieve and H. S. Littlepage to be Temp. Lts.

W. A. R. Ross and P. V. MacGarry to be Lts. on prob. and are secd. under the provisions of Art. 205, Royal Warrant for Pay and Promotion, 1926.

TERRITORIAL ARMY.

Hon. Col. J. Griffiths vacates the appt. of Hon. Col. R.A.M.C. Units, 54th (E. Anglian) Div. T.A., on completion of tenure.

Col. G. A. Troup to be Hon. Col. R.A.M.C. Units, 54th (E. Anglian) Div., T.A.

Lt. N. W. Hammer to be Capt.

INDIAN MEDICAL SERVICE.

Lt.-Col. (Bt. Col.) A. Spitteler to be Col.

Lt.-Col. F. F. Elwes retires.

To be Capts.: F. E. B. Manning and S. Smyth.

To be Lts.: J. Quigley, R. A. Haythornthwaite, R. I Alexander and J. C. Lamont.

To be Temp. Lts.: Nanikram Chartsing Ramchandan Hasibul Hasan Khan, Eruch Ardeshir Darukhanvala an Michael Rodriques.

Temp. Capt. Debendra Chandra Majumdar relinquishe his temp. commn. and retains his rank.

COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS.

The following have been granted commissions a Lieutenants on Probation in the R.A.M.C.: C. L. Day an G. T. L. Archer (Trinity Coll., Dublin); D. R. W. Burbur (London Hosp.); P. J. L. Capon (St. Thomas's Hosp.) P. Dwyer (Glasgow Univ.); K. McNeill (Edinburgh Univ.) M. R. Burke and P. W. A. Agnew (St. George's Hosp.) J. C. Gilroy (Edinburgh Univ.); J. W. Kendall (King Coll.); W. A. R. Ross (Edinburgh Univ.); P. V. MacGarr (London Hosp.); and J. G. Weston (Guy's Hosp.).

DEATHS IN THE SERVICES.

Sir Robert Porter, whose death was announced in th column in our last issue, was the son of Mr. Andre Porter, and was born in Donegal in 1858. He w educated at Foyle College, Londonderry, in Paris, ar at Glasgow University, where he graduated in medici and surgery in 1879. In 1881 he entered the Roy Army Medical Corps and saw service with the Ashan Expedition of 1895–96, and was present at the capture Kumasi. He also took part in the South African war ar was awarded for his services two medals and seven clasp In the late war, as Director of Medical Services of th Second Army in France, from its formation in 1914 unt its dispersion in July, 1917, he at one time had over 12 medical officers under his administrative control, includir the medical services and 28 divisions, corps troops ar army troops, 13 casualty clearing stations, 3 mobile labor tories, 14 sanitary sections and 5 army schools of sanit tion—a vast organisation which he had himself built u The Second Army numbered over 800,000 men at th Battle of Passchendaele, and was probably the large individual army of modern times; it was employed in th region of Ypres, and received the first gas attack. He w mentioned six times in despatches, was created C.B. in 191 C.M.G. in 1919, and K.C.B. in 1921. He was a Command of the Order of the Crown and he held the Croix de Guer both Belgian honours. He married in 1903 Mary, daught of the late Mr. John Johnston, of Barnard Castle, w survives him with three sons.

NATIONAL HOSPITAL, QUEEN-SQUARE.—The annu general meeting will be held at the hospital on Tuesda March 27th, at 4.30 P.M.
